Bamboo documentation

Bamboo is a continuous integration and delivery tool that ties automated builds, tests, and releases in a single workflow.

Get started

New to using Bamboo? Get started with some introductory information.
Let's start

What's new

Getting started with Bamboo

This page describes how to install, set up, and start using Bamboo.

If you're upgrading Bamboo, read the Bamboo upgrade guide instead of this page.

For production installs we recommend that you read Bamboo best practice - system requirements.

Atlassian Bamboo is a continuous integration (CI) and deployment server. Bamboo assists software development teams by providing:

- automated building and testing of software source-code status.
- updates on successful and failed builds.
- reporting tools for statistical analysis.

Please see the following pages for information about getting started with Bamboo:

- Bamboo best practice - system requirements
- Understanding the Bamboo CI Server - a conceptual overview of using Bamboo for continuous integration (CI).

1. Install and start Bamboo

See one of:

- Installing Bamboo on Linux
- Installing Bamboo on Mac OS X
- Installing Bamboo on Windows

Once it's started, you can access Bamboo in your browser at http://localhost:8085/.

2. Set up notifications

Bamboo can send build result notifications using:

- Hipchat - see Integrating Bamboo with Hipchat
- Email - see Configuring Bamboo to send SMTP Email
- Other services - see Notifications

3. Get building with Bamboo

Bamboo has the concept of a 'plan' to look after the configuration for a build. So, to run your first build, you create and run a plan:

- Getting started with Java and Bamboo - a guide to setting up a simple CI workflow for Java code.
- Getting started with .NET and Bamboo - a guide to setting up a simple CI workflow on Windows.

Understanding the Bamboo CI Server

Bamboo is a continuous integration (CI) server that can be used to automate the release management for a software application, creating a continuous delivery pipeline.

What does this mean?

CI is a software development methodology in which a build, unit tests and integration tests are performed, or triggered, whenever code is committed to the repository, to ensure that new changes integrate well into the existing code base. Integration builds provide early 'fail fast' feedback on the quality of new changes.

Release management describes the steps that are typically performed to release a software application, including building and functional testing, tagging releases, assigning versions, and deploying and activating the new version in production.
What problem does Bamboo solve?

If you are a solo developer, then using Bamboo gives you:

- an automated, and therefore reliable, build and test process, leaving you free to code more.
- a way to manage builds that have different requirements or targets.
- automatic deployment to a server, such as the App Store or Google Play.

If you work in a team, then as well as the above advantages, using Bamboo also means that:

- your build and test process is not dependent on a specific local environment.
- builds and integration tests are triggered automatically as soon as a developer commits code (continuous integration).

If you work on a large, complex application, then, in addition to all the above advantages, using Bamboo means that:

- you can optimize build performance through parallelism.
- you can leverage elastic resources.
- you can deploy continuously, for example to user acceptance testing (UAT).
- you can implement release management.

How does Bamboo do this?

- Bamboo is the central management server which schedules and coordinates all work.
- Bamboo itself has interfaces and plugins for lots of types of work.
- Bamboo first gets your source from a source repository (lots of plugins here for a variety of systems).
- Then Bamboo starts the build - that can be done by calling something like MSBuild to build your Visual Studio solution, or Maven to call your compiler and linker - whatever you use.
- Once your solution or project is built, you have “artifacts” (build results, for example, an executable app, config files, etc.).
- You can do additional things with the build artifacts:
  - zip them up into a ZIP file and copy them somewhere.
  - run an install builder on them and create an MSI.
  - install them on a test server to make sure everything installs just fine.
- Bamboo provides a web front-end for configuration and for reporting the status of builds.
What does Bamboo need?

Bamboo schedules and coordinates the work involved in building and testing your application. Therefore, to use Bamboo, you will need to already have the following set up:

- a code repository that contains the complete source code for the project.
- build scripts
- test suites

It is generally assumed that the person who commits a change to the code is responsible for fixing any resulting build errors immediately.

How is a Bamboo workflow organized?

Bamboo uses the concept of a 'plan' with 'jobs' and 'tasks' to configure and order the actions in the workflow.

Project

- Has none, one, or more, plans.
- Provides reporting (using the wallboard, for example) across all plans in the project.
- Provides links to other applications.
- Allows setting up permissions for all the plans it contains

Plan

- Has a single stage, by default, but can be used to group jobs into multiple stages.
- Processes a series of one or more stages that are run sequentially using the same repository.
- Specifies the default repository.
- Specifies how the build is triggered, and the triggering dependencies between the plan and other plans in the project.
- Specifies notifications of build results.
- Specifies who has permission to view and configure the plan and its jobs.
- Provides for the definition of plan variables.

Stage

- Has a single job, by default, but can be used to group multiple jobs.
- Processes its jobs in parallel, on multiple agents (where available).
- Must successfully complete all its jobs before the next stage in the plan can be processed.
- May produce artifacts that can be made available for use by a subsequent stage.

Job

- Processes a series of one or more tasks that are run sequentially on the same agent.
- Controls the order in which tasks are performed.
- Collects the requirements of individual tasks in the job, so that these requirements can be matched with agent capabilities.
- Defines the artifacts that the build will produce.
- Can only use artifacts produced in a previous stage.
- Specifies any labels with which the build result or build artifacts will be tagged.

Task

- Is a small discrete unit of work, such as source code checkout, executing a Maven goal, running a script, or parsing test results.
- Is run sequentially within a job on a Bamboo working directory.
Understanding the Bamboo CI Server v5.14

Bamboo is a continuous integration (CI) server that can be used to automate the release management for a software application, creating a continuous delivery pipeline.

What does this mean?

CI is a software development methodology in which a build, unit tests and integration tests are performed, or triggered, whenever code is committed to the repository, to ensure that new changes integrate well into the existing code base. Integration builds provide early 'fail fast' feedback on the quality of new changes.

Release management describes the steps that are typically performed to release a software application, including building and functional testing, tagging releases, assigning versions, and deploying and activating the new version in production.

How does Bamboo do this?

- Bamboo is the central management server which schedules and coordinates all work.
- Bamboo itself has interfaces and plugins for lots of types of work.
- Bamboo first gets your source from a source repository (lots of plugins here for a variety of systems).
- Then Bamboo starts the build - that can be done by calling something like MSBuild to build your Visual Studio solution, or Maven to call your compiler and linker - whatever you use.
- Once your solution or project is built, you have "artifacts" (build results, for example, an executable app, config files, etc.).
- You can do additional things with the build artifacts:
  - zip them up into a ZIP file and copy them somewhere.
  - run an install builder on them and create an MSI.
  - install them on a test server to make sure everything installs just fine.
- Bamboo provides a web front-end for configuration and for reporting the status of builds.

What does Bamboo need?

Bamboo schedules and coordinates the work involved in building and testing your application. Therefore, to use Bamboo, you will need to already have the following set up:

- a code repository that contains the complete source code for the project.
- build scripts
- test suites

It is generally assumed that the person who commits a change to the code is responsible for fixing any resulting build errors immediately.

How is a Bamboo workflow organized?
Bamboo uses the concept of a 'plan' with 'jobs' and 'tasks' to configure and order the actions in the workflow.

### Project
- Has none, one, or more, **plans**.
- Provides **reporting** (using the wallboard, for example) across all plans in the project.
- Provides links to other applications.
- Allows setting up permissions for all the plans it contains.

### Plan
- Has a single **stage**, by default, but can be used to group **jobs** into multiple stages.
- Processes a series of one or more stages that are run **sequentially** using the **same** repository.
- Specifies the default repository.
- Specifies how the build is **triggered**, and the triggering dependencies between the plan and other plans in the project.
- Specifies **notifications** of **build results**.
- Specifies who has **permission** to view and configure the plan and its jobs.
- Provides for the definition of **plan variables**.

### Stage
- Has a single **job**, by default, but can be used to group multiple jobs.
- Processes its jobs in **parallel**, on **multiple agents** (where available).
- Must successfully complete all its jobs before the next **stage** in the **plan** can be processed.
- May produce **artifacts** that can be made available for use by a subsequent stage.

### Job
- Processes a series of one or more **tasks** that are run **sequentially** on the **same** **agent**.
- Controls the order in which tasks are performed.
- Collects the **requirements** of individual tasks in the job, so that these requirements can be matched with agent **capabilities**.
- Defines the **artifacts** that the build will produce.
- Can only use artifacts produced in a previous stage.
- Specifies any labels with which the **build result** or **build artifacts** will be tagged.

### Task
- Is a small discrete unit of work, such as source code checkout, executing a Maven goal, running a script, or parsing test results.
- Is run **sequentially** within a **job** on a Bamboo working directory.

---

### Understanding the Bamboo CI Server v6.1

Bamboo is a continuous integration (CI) server that can be used to automate the release management for a software application, creating a continuous delivery pipeline.
What does this mean?

CI is a software development methodology in which a build, unit tests and integration tests are performed, or triggered, whenever code is committed to the repository, to ensure that new changes integrate well into the existing code base. Integration builds provide early ‘fail fast’ feedback on the quality of new changes.

Release management describes the steps that are typically performed to release a software application, including building and functional testing, tagging releases, assigning versions, and deploying and activating the new version in production.

Continuous Integration

What problem does Bamboo solve?

If you are a solo developer, then using Bamboo gives you:

- an automated, and therefore reliable, build and test process, leaving you free to code more.
- a way to manage builds that have different requirements or targets.
- automatic deployment to a server, such as the App Store or Google Play.

If you work in a team, then as well as the above advantages, using Bamboo also means that:

- your build and test process is not dependent on a specific local environment.
- builds and integration tests are triggered automatically as soon as a developer commits code (continuous integration).

If you work on a large, complex application, then, in addition to all the above advantages, using Bamboo means that:

- you can optimize build performance through parallelism.
- you can leverage elastic resources.
- you can deploy continuously, for example to user acceptance testing (UAT).
- you can implement release management.

How does Bamboo do this?

- Bamboo is the central management server which schedules and coordinates all work.
- Bamboo itself has interfaces and plugins for lots of types of work.
- Bamboo first gets your source from a source repository (lots of plugins here for a variety of systems).
- Then Bamboo starts the build - that can be done by calling something like MSBuild to build your Visual Studio solution, or Maven to call your compiler and linker - whatever you use.
Once your solution or project is built, you have “artifacts” (build results, for example, an executable app, config files, etc.).

You can do additional things with the build artifacts:

- zip them up into a ZIP file and copy them somewhere.
- run an install builder on them and create an MSI.
- install them on a test server to make sure everything installs just fine.

Bamboo provides a web front-end for configuration and for reporting the status of builds.

**What does Bamboo need?**

Bamboo schedules and coordinates the work involved in building and testing your application. Therefore, to use Bamboo, you will need to already have the following set up:

- a code repository that contains the complete source code for the project.
- build scripts
- test suites

It is generally assumed that the person who commits a change to the code is responsible for fixing any resulting build errors immediately.

**How is a Bamboo workflow organized?**

Bamboo uses the concept of a 'plan' with 'jobs' and 'tasks' to configure and order the actions in the workflow.

**Project**

- Has none, one, or more, plans.
- Provides reporting (using the wallboard, for example) across all plans in the project.
- Allows setting up permissions for all the plans it contains

**Plan**

- Has a single stage, by default, but can be used to group jobs into multiple stages.
- Processes a series of one or more stages that are run sequentially using the same repository.
- Specifies the default repository.
- Specifies how the build is triggered, and the triggering dependencies between the plan and other plans in the project.
- Specifies notifications of build results.
- Specifies who has permission to view and configure the plan and its jobs.
- Provides for the definition of plan variables.

**Stage**

- Has a single job, by default, but can be used to group multiple jobs.
- Processes its jobs in parallel, on multiple agents (where available).
- Must successfully complete all its jobs before the next stage in the plan can be processed.
- May produce artifacts that can be made available for use by a subsequent stage.

**Job**

- Processes a series of one or more tasks that are run sequentially on the same agent.
- Controls the order in which tasks are performed.
- Collects the requirements of individual tasks in the job, so that these requirements can be matched with agent capabilities.
- Defines the artifacts that the build will produce.
- Can only use artifacts produced in a previous stage.
- Specifies any labels with which the build result or build artifacts will be tagged.

**Task**

- Is a small discrete unit of work, such as source code checkout, executing a Maven goal, running a script, or parsing test results.
- Is run sequentially within a job on a Bamboo working directory.
AWS account for Bamboo

Create and configure your AWS (Amazon Web Services) account for smooth Elastic Bamboo setup and maintenance.

<table>
<thead>
<tr>
<th>Bamboo</th>
<th>AWS account required</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud</td>
<td>no</td>
<td>Runs builds on local agents and/or in cloud (with Elastic Bamboo)</td>
</tr>
<tr>
<td>Server</td>
<td>no</td>
<td>Runs builds on local agents and/or in cloud (with Elastic Bamboo)</td>
</tr>
</tbody>
</table>

Creating AWS accounts

You can create an AWS root account on [http://aws.amazon.com](http://aws.amazon.com).

Cost management

The cost of all Amazon Web Services usage is billed to your AWS account, separately from your Atlassian subscription. It means that you are responsible for all AWS usage costs incurred on your AWS account.

The AWS account billing doesn’t distinguish between your Bamboo EC2 usage and your other (non-Bamboo) EC2 usage.

Recommendations

We respect different ways in which you might want to structure your working environment. However, we thought we’d let you know what is important from our perspective.

IAM (AWS Identity and Access Management)

For security reasons, Atlassian recommends using IAM for user and access key management. For more information, see [IAM Best Practices](https://docs.aws.amazon.com/IAM/latest_USER_guide/best-practices.html) and [IAM Users and Groups](https://docs.aws.amazon.com/IAM/latest/UserGuide/idRoleId.html).

Tips:

- Bamboo uses access keys for authorization
- Lost access keys? You must generate a new key set in the AWS account console. For more information, see [How Do I Get Security Credentials?](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_createVien.html)

Getting started with Java and Bamboo

This tutorial outlines how to use Bamboo to run, and get rapid feedback on, builds for your Java project. Bamboo has the concept of a ‘plan’ to look after the configuration for your continuous integration workflow. So, to run your first build, you’ll create and run a Bamboo plan.
Information you need before you begin

This tutorial assumes you are using Bamboo Cloud, which allows us to make some assumptions about the resources available to Bamboo. You can still use the tutorial if you are using Bamboo Server installed on your local network. You just need to make sure you or your company administrator have properly installed and configured Bamboo for running plans.

We also assume you have an individual Bitbucket account. If you don’t, it only takes minutes to create one, and you can always delete it after you’re done.

1. Create a project and plan

A Bamboo plan specifies the source code repository, the tasks to run in your build, and when to trigger a build. We start by creating a new plan:

   1. Log into your Bamboo instance as a user with permissions to create plans.
   2. Choose Create > Create a new plan from the menu bar.

Every plan belongs to a project. We don’t have a project yet, so choose Project > New Project, and enter details for both the project and plan.

   - **Project name**: TestProject
   - **Project key**: TP
   - **Plan name**: Tutorials
   - **Plan key**: TUT
   - **Description**: Build atlassian tutorials

See Configuring plans for more details.

2. Connect to a source repository

Bamboo needs to know where the source code repository is located, and needs permissions to access the repo, so that it can check out the code when it runs a build. Enter your Bitbucket credentials, and click Load Repositories to browse to your repository.

Connect to the demonstration atlassian_tutorial/helloworld repo on Bitbucket for this tutorial, if you like.
3. Choose how builds are triggered

We can choose how Bamboo gets prompted to run our plan build. For this tutorial, we want Bamboo to run the build when code is committed to the repo:

![Bamboo screenshot](image)

<table>
<thead>
<tr>
<th>Trigger type</th>
<th>How build triggers work</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository triggers the build when</td>
<td>How should Bamboo trigger builds for this plan? (dependent builds are automatically triggered)</td>
</tr>
<tr>
<td>Trigger IP addresses</td>
<td>Bamboo ensures that triggers originate from IP addresses of the repository server(s). You can authorise additional IP addresses here, separated by a comma.</td>
</tr>
</tbody>
</table>

Leave the **Trigger IP addresses** setting empty.

See [Triggering builds](#) for more details.

4. Configure tasks

Each plan needs to have at least one task specified. Tasks do the real work of the plan.

- **The source code checkout task**
  
  A newly created plan has a default Source Code Checkout task that gets the source code from the source repository specified earlier.
  
  See [Checking out code](#) for details.

- **The builder task**
We also want to compile the code, and run the unit and integration tests. We'll add a builder task to the Bamboo plan to do that. We assume that your project already has a build process set up that Bamboo can call.

Click Add Task, then Builder and choose the task that matches the build tool for your project. Expand one of the following sections to see configuration details specific to that builder task:

### Ant Configuration

**Task Description**

**Executable**

Ant

**Build File**

build.xml

**Target**

clean test

The target you want to execute. You can also define system properties such as -Djava.awt.headless=true.

### Maven 3.x Configuration

**Task Description**

**Executable**

Maven 3

**Goal**

clean test

The goal you want to execute. You can also define system properties such as -Djava.awt.headless=true.

- Use Maven Return Code
  
  When determining build success, Bamboo checks Maven return code and searches the log for "BUILD SUCCESS". By checking this option, you will configure Bamboo to skip log parsing. This may fail on some Maven versions/operating systems.

Bamboo also supports Maven 1.0 and Maven 2.0.

### Grails...
Grails Configuration

<table>
<thead>
<tr>
<th>Task Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Executable</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>

Add New Executable

<table>
<thead>
<tr>
<th>Grails Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>clean</td>
</tr>
<tr>
<td>test-app</td>
</tr>
</tbody>
</table>

Use a new line to separate Grails commands. Bamboo will automatically append "-non-interactive" to each command.

Note that:

- A build tool needs to be installed on the Bamboo server machine before you can use the Bamboo task.
- There are plugins available for Bamboo that add build tasks for other tools, such as Gant and Gradle. See the [Atlassian Marketplace](https://marketplace.atlassian.com) for details.

### Getting the test results

Your tests will be run when the builder task compiles the code. Each of the builder tasks above has a section to tell Bamboo to expect test results and where to look for them. You can specify a custom results location if your project directory doesn't use the conventional structure.

### Where should Bamboo look for the test result files?

- [ ] The build will produce test results.
  - If checked, the build will fail if no tests are found. Test output must be in JUnit XML format.

<table>
<thead>
<tr>
<th>Test Results Directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ ] Lock in the standard test results directory.</td>
</tr>
<tr>
<td>[ ] Specify custom results directories</td>
</tr>
</tbody>
</table>

Where should Bamboo look for the test result files?

See [Configuring jobs](https://confluence.atlassian.com/display/DOCS/Configuring+jobs) and [Configuring tasks](https://confluence.atlassian.com/display/DOCS/Configuring+tasks) for details.

### 5. Run!

Enable the plan, and click **Create**.

You should see the plan run. Bamboo will:

- Connect to the code repository
- Check out the source code
- Compile the code
- Run unit and integration tests
- Report back the test results

The 'Plan Summary' tab will report whether the build succeeded or not.

Tests in the appropriate directory in the source code repository will be run automatically as part of the build, and the test results will be displayed in Bamboo.

Now, whenever you commit a change to the repository, Bamboo will build your source code and report on your test results.

### 6. Get feedback
Bamboo displays a summary of the results of the build on the dashboard.

You can get further information about the build in the following ways:

- Build results for one or more plans can be displayed on a wallboard.
- You can get notifications about build results sent to you by email, IM and RSS feed.
- You can get build statistics about plans, and about developers contributing code to the build.
- You can drill down into the results to see the code changes that triggered the build, and the tests that were run for that build.

See Getting feedback for details.

Getting started with .NET and Bamboo

This page describes how your development team can start using the Bamboo continuous integration server to get rapid feedback on your .NET project.

ℹ️ You may want to read Understanding the Bamboo CI Server first.

We assume that you already have:

- Bamboo installed and running. See Installing and upgrading for details. You'll want user accounts in Bamboo for each member of your team.
- Source code under version control. Each team member will have access to the repository.
- Tests, as part of the source code for the project.
- A command that builds the code and executes the tests.

The continuous integration workflow we want is:

1. A developer commits code.
2. Bamboo builds the project:
   a. Connects to the repository and checks out the source code.
   b. Compiles the code.
   c. Runs the unit and integration tests.
3. Bamboo provides feedback on the test results.

How do we achieve this with Bamboo?

Well, we'll create a new Bamboo plan that knows how to check out and build our source code, and then report on our test results.

On this page:

Create a Bamboo plan
1. Plan details
2. Choose a source repository
3. Triggering the build
4. Configure tasks
   The source code checkout task
   The builder task
   Getting the test results
5. Go!
Get feedback

Related pages:

- Getting started with Java and Bamboo

Create a Bamboo plan

A Bamboo plan is where you define the details of your continuous integration workflow.

A plan allows us to specify a source code repository, when Bamboo gets triggered to run the build, and how Bamboo should provide feedback on the test results.

1. Plan details

Click Create Plan in the menu bar, and then Create a New Plan.

Every plan belongs to a project. We don't have a project yet, so choose Project > New Project, and enter details for both the project and plan.

See Configuring plans for details.
2. Choose a source repository

Bamboo needs to know where the source code repository is located, and needs access to the repo so that it can check out the code when it runs a build.

Choose the repository type from **Source Repository**, and provide access details such as username and password.

See **Linking to source code repositories** for details.

### Source Repositories

<table>
<thead>
<tr>
<th>Source Repository</th>
<th>Git</th>
</tr>
</thead>
<tbody>
<tr>
<td>Git support works best if the Git executable capability is defined for agents. If not defined, Bamboo will use JGit, which currently does not support submodules.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Repository URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>The URL of Git repository.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Branch</th>
</tr>
</thead>
<tbody>
<tr>
<td>The name of the branch (or tag) containing source code.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Authentication Type</th>
<th>None</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use shallow clones</td>
<td></td>
</tr>
<tr>
<td>Fetches the shallowest commit history possible. Do not use if your build depends on full repository history.</td>
<td></td>
</tr>
</tbody>
</table>

3. Triggering the build

We can choose how Bamboo gets triggered to run the plan build.

We want Bamboo to build the project whenever code is checked into the repository.

Choose **Trigger type > Repository triggers the build...**, and optionally, specify an IP address for the repository server.

See **Triggering builds** for details.
4. Configure tasks

Each plan needs to have one or more tasks specified. Tasks do the real work of the plan.

**The source code checkout task**

A newly created plan has a default Source Code Checkout task that gets the source code from the source repository specified earlier. See [Checking out code](#) for details.

**The builder task**

We also want to compile the code. We'll add a builder task to the Bamboo plan to do that. We assume that your project already has a build process set up that Bamboo can call upon.

Click **Add Task**, then **Builder** and choose the task that matches the build tool for your project. Expand one of the following sections to see configuration details specific to that builder task:

> **MSBuild**

**MSBuild Configuration**

<table>
<thead>
<tr>
<th>Task Description</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Executable*</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSBuild v2.0 (32bit)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Project File*</th>
</tr>
</thead>
<tbody>
<tr>
<td>YourSolution.sln</td>
</tr>
</tbody>
</table>

The solution, project file, or MSBuild project to execute when this job builds

<table>
<thead>
<tr>
<th>Options</th>
</tr>
</thead>
</table>

The MSBuild.exe command line switches you wish to include.

> **NAnt**
**NAnt Configuration**

Task Description

**Executable**

NAnt

Add New Executable

Build File

default.build

The name of the NAnt build file that you want to execute when this Job builds

Targets

run

The NAnt targets you want Bamboo to execute when this Job builds

Options

The NAnt command line options you wish to include.

See http://nant.sourceforge.net/ for information about NAnt.

**Visual Studio Configuration**

Task Description

**Executable**

Visual Studio 2010

Add New Executable

Solution

The Visual Studio solution file you want Bamboo to execute when this Job builds

Options

The devenv command line options you wish to include.

Platform

x86

The platform toolset required to compile your Solution.

Note that a build tool needs to be installed on the Bamboo server machine before you can use the Bamboo task.

See Configuring a builder task for details.

**Getting the test results**

Now we want to run the unit and integration tests, and display the results from those. You need to set up one of the MSTest, NUnit or MBUnit tasks so Bamboo can get and display the test results. You can specify a custom results location if your project directory doesn't use the conventional structure.

See Configuring a test task for details.

5. Go!
Enable the plan, and click **Create**.

You should see the plan run. The 'Plan Summary' tab will report whether the build succeeded or not.

Tests in the appropriate directory in the source code repository will be run automatically as part of the build, and the test results will be displayed in Bamboo.

Now, whenever you commit a change to the repository, Bamboo will build your source code and report on your test results.

**Get feedback**

Bamboo displays a summary of the results of the build on the dashboard.

You can get further information about the build in the following ways:

- Build results for one or more plans can be displayed on a wallboard.
- You can get notifications about build results sent to you by email, IM and RSS feed.
- You can get build statistics about plans, and about developers contributing code to the build.
- You can drill down into the results to see the code changes that triggered the build, and the tests that were run for that build.

See **Getting feedback** for details.

### Getting started with PHP and Bamboo

This page describes how to use Bamboo to get rapid feedback on your PHP project. The worked example builds a Bamboo plan where a developer commits code and Bamboo responds by:

- Connecting to the code repository
- Checking out the source code
- Compiling the code
- Running unit and integration tests
- Reporting back test results

**On this page:**

- Information you need before you begin
- Step 1: Install the PHP base code framework
- Step 2: Install PHPUnit
- Step 3. Create a project and plan
- Step 4. Configure tasks
- Get feedback

**Related pages:**

- Getting started with .NET and Bamboo
- Getting started with Ruby and Bamboo

### Information you need before you begin

This introduction assumes you are using Bamboo Server installed on your local network. You need to make sure you or your company administrator have properly installed and configured Bamboo for running plans.

You will also need to install:

- The PHP framework
- PHPUnit testing framework

### Step 1: Install the PHP base code framework

In order to get full functionality from Bamboo and PHP, you will need to install the PHP base code framework. If you are using Ubuntu, then use the following command to install PHP.

```
$ sudo apt-get install php5-cli
```

See also:

- Installing PHP on MacOS
- Installing PHP on Windows
Step 2: Install PHPUnit

PHPUnit.de provides an excellent PHP archive resource called PHAR.

```bash
$ wget https://phar.phpunit.de/phpunit.phar  // download the PHPUnit packages
$ chmod +x phpunit.phar    // make PHPUnit executable
$ mv phpunit.phar /usr/local/bin/phpunit    // copy PHPUnit into your path
$ phpunit --version    // double check it's installed completely
```

If you prefer, you may use Composer or PEAR to download and install PHPUnit along with its dependencies, however these approaches are beyond the scope of this introduction.

Step 3. Create a project and plan

1. Create a new project

A Bamboo plan defines the details of your continuous integration workflow. You use a plan to identify the source code repository, specify the tasks to run in your build, and when to trigger a build. Each plan belongs to a project. You can add a plan to an existing project or create a new project. In this example, you create both a new project and a new plan in that project.

1. Log into your Bamboo instance as a user with permissions to create plans.
2. Choose Create > Create a New Plan from the menu bar.

Every plan belongs to a project. We don't have a project yet, so choose **Project > New Project**, and enter details for both the project and plan.

![Project Creation Window]

- **Project Name**: TestProject
- **Project Key**: TP

2. Configure the plan details

Bamboo needs to know the Plan name, Plan key and a brief description of what the plan is for. See Configuring plans for more details.

![Plan Configuration Window]

- **Plan name**: Tutorials
- **Description**: Build atlassian tutorials
TUT

Description

Build Atlassian tutorials

3. Choose a source repository

Bamboo needs to know where the source code repository is located, and needs access to the repo so that it can check out the code when it runs a build. See Linking to source code repositories for more details.

<table>
<thead>
<tr>
<th>Source repositories</th>
<th>Bitbucket</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Source repository</strong></td>
<td>Bitbucket</td>
</tr>
<tr>
<td><strong>Username</strong></td>
<td>MyBitbucketUsername</td>
</tr>
<tr>
<td><strong>Password</strong></td>
<td>***************</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>atlassian_tutorial/helloworld (git)</td>
</tr>
<tr>
<td><strong>Branch</strong></td>
<td>master</td>
</tr>
<tr>
<td><strong>Use shallow clones</strong></td>
<td>Set this checkbox</td>
</tr>
</tbody>
</table>

4. Triggering the build

We can choose how Bamboo gets triggered to run the plan build:

<table>
<thead>
<tr>
<th>Trigger</th>
<th>How build triggers work</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Trigger type</strong></td>
<td>Repository triggers the build when</td>
</tr>
<tr>
<td><strong>Trigger IP</strong></td>
<td>How should Bamboo trigger builds for this plan? (dependent builds are automatically triggered)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Trigger type</th>
<th>How build triggers work</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository triggers the build when</strong></td>
<td>How should Bamboo trigger builds for this plan? (dependent builds are automatically triggered)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Trigger IP</th>
<th>How build triggers work</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Trigger IP</strong></td>
<td>Optionally add an IP address for your repository</td>
</tr>
</tbody>
</table>

See Triggering builds for more details.
Step 4. Configure tasks

Each plan needs to have at least one task specified. Tasks do the real work of the plan.

The source code checkout task

A newly created plan has a default Source Code Checkout task that gets the source code from the source repository specified earlier. See Checking out code for details.

Unit testing

Unit testing for PHP is completed using the PHPUnit testing framework. This is a port of the popular Java JUnit testing framework to PHP. PHPUnit provides also produces test results in the JUnit XML format required by Bamboo.

You will need to add a server executable capability to run PHPUnit:

1. Go to Overview > Server capabilities.
2. Click Add capability and complete the configuration using the following:
   
   Capability type
   Executable

   Type
   PHPUnit

   Executable label
   PHPUnit x.x

   Path
   Path to the PHPUnit executable e.g. /usr/bin/phpunit-x.x
3. Click Add to add the PHPUnit capability.

Now you can create a PHPUnit testing task:
Getting the test results

Your tests will be run when the builder task compiles the code. Each of the builder tasks above has a section to tell Bamboo to expect test results and where to look for them. You can specify a custom results location if your project directory doesn't use the conventional structure.

See Jobs and tasks for details.

Step 5: Go!

Enable the plan, and click Create.

You should see the plan run. The 'Plan Summary' tab will report whether the build succeeded or not.

Tests in the appropriate directory in the source code repository will be run automatically as part of the build, and the test results will be displayed in Bamboo.

Now, whenever you commit a change to the repository, Bamboo will build your source code and report on your test results.

Get feedback
Bamboo displays a summary of the results of the build on the dashboard.

You can get further information about the build in the following ways:

- Build results for one or more plans can be displayed on a wallboard.
- You can get notifications about build results sent to you by email, IM and RSS feed.
- You can get build statistics about plans, and about developers contributing code to the build.
- You can drill down into the results to see the code changes that triggered the build, and the tests that were run for that build.

See Getting feedback for details.

### Getting started with PHP and Bamboo v5.14

This page describes how to use Bamboo to get rapid feedback on your PHP project. The worked example builds a Bamboo plan where a developer commits code and Bamboo responds by:

- Connecting to the code repository
- Checking out the source code
- Compiling the code
- Running unit and integration tests
- Reporting back test results

### On this page:

- Information you need before you begin
- Step 1: Install the PHP base code framework
- Step 2: Install PHPUnit
- Step 3. Create a project and plan
- Step 4. Configure tasks
- Get feedback

### Related pages:

- Getting started with .NET and Bamboo
- Getting started with Ruby and Bamboo

### Information you need before you begin

This introduction assumes you are using Bamboo Server installed on your local network. You need to make sure you or your company administrator have properly installed and configured Bamboo for running plans.

You will also need to install:

- The PHP framework
- PHPUnit testing framework

### Step 1: Install the PHP base code framework

In order to get full functionality from Bamboo and PHP, you will need to install the PHP base code framework. If you are using Ubuntu, then use the following command to install PHP.

```
$ sudo apt-get install php5-cli
```

See also:

- Installing PHP on MacOS
- Installing PHP on Windows

### Step 2: Install PHPUnit

PHPUnit.de provides an excellent PHP archive resource called PHAR.

```
$ wget https://phar.phpunit.de/phpunit.phar  // download the PHPUnit packages
$ chmod +x phpunit.phar  // make PHPUnit executable
$ mv phpunit.phar /usr/local/bin/phpunit  // copy PHPUnit into your path
$ phpunit --version  // double check it's installed completely
```
If you prefer, you may use Composer or PEAR to download and install PHPUnit along with its dependencies, however these approaches are beyond the scope of this introduction.

Step 3. Create a project and plan

1. Create a new project

A Bamboo plan defines the details of your continuous integration workflow. You use a plan to identify the source code repository, specify the tasks to run in your build, and when to trigger a build. Each plan belongs to a project. You can add a plan to an existing project or create a new project. In this example, you create both a new project and a new plan in that project.

1. Log into your Bamboo instance as a user with permissions to create plans.
2. Choose Create > Create a New Plan from the menu bar.

Every plan belongs to a project. We don’t have a project yet, so choose Project > New Project, and enter details for both the project and plan.

<table>
<thead>
<tr>
<th>Project</th>
<th>New Project</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project Name</td>
<td>TestProject</td>
</tr>
<tr>
<td>Project Key</td>
<td>TP</td>
</tr>
</tbody>
</table>

2. Configure the plan details

Bamboo needs to know the Plan name, Plan key and a brief description of what the plan is for. See Configuring plans for more details.

<table>
<thead>
<tr>
<th>Plan name</th>
<th>Tutorials</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plan key</td>
<td>TUT</td>
</tr>
<tr>
<td>Description</td>
<td>Build Atlassian tutorials</td>
</tr>
</tbody>
</table>

3. Choose a source repository

Bamboo needs to know where the source code repository is located, and needs access to the repo so that it can check out the code when it runs a build. See Linking to source code repositories for more details.
1. Source Repository
   - Bitbucket
2. Username
   - Your Bitbucket username
3. Password
   - Your Bitbucket password
4. Repository
   - atlassian_tutorial/hellworld (git)
5. Branch
   - master
6. Use shallow clones
   - Set this checkbox

4. Triggering the build

We can choose how Bamboo gets triggered to run the plan build:

- **Trigger type**: Repository triggers the build when changes are committed
- **Trigger IP**: Optionally add an IP address for your repository

See Triggering builds for more details.

Step 4. Configure tasks

Each plan needs to have at least one task specified. Tasks do the real work of the plan.

**The source code checkout task**

A newly created plan has a default Source Code Checkout task that gets the source code from the source repository specified earlier. See Checking out code for details.

**Unit testing**

Unit testing for PHP is completed using the PHPUnit testing framework. This is a port of the popular Java JUnit testing framework to PHP. PHPUnit provides also produces test results in the JUnit XML format required by Bamboo.

You will need to add a server executable capability to run PHPUnit:

1. Go to Overview > Server capabilities.
2. Click Add capability and complete the configuration using the following:
   - **Capability type**: Executable
3. Click **Add** to add the PHPUnit capability.

Now you can create a PHPUnit testing task:

![PHPUnit configuration](image)

**Getting the test results**

Your tests will be run when the builder task compiles the code. Each of the builder tasks above has a section to tell Bamboo to expect test results and where to look for them. You can specify a custom results location if your project directory doesn't use the conventional structure.

![Where should Bamboo look for the test result files?](image)

**Step 5: Go!**

Enable the plan, and click **Create**.
You should see the plan run. The 'Plan Summary' tab will report whether the build succeeded or not.

Tests in the appropriate directory in the source code repository will be run automatically as part of the build, and the test results will be displayed in Bamboo.

Now, whenever you commit a change to the repository, Bamboo will build your source code and report on your test results.

Get feedback

Bamboo displays a summary of the results of the build on the dashboard.

You can get further information about the build in the following ways:

- Build results for one or more plans can be displayed on a wallboard.
- You can get notifications about build results sent to you by email, IM and RSS feed.
- You can get build statistics about plans, and about developers contributing code to the build.
- You can drill down into the results to see the code changes that triggered the build, and the tests that were run for that build.

See Getting feedback for details.

Getting started with PHP and Bamboo v6.1

This page describes how to use Bamboo to get rapid feedback on your PHP project. The worked example builds a Bamboo plan where a developer commits code and Bamboo responds by:

- Connecting to the code repository
- Checking out the source code
- Compiling the code
- Running unit and integration tests
- Reporting back test results

On this page:

- Information you need before you begin
- Step 1: Install the PHP base code framework
- Step 2: Install PHPUnit
- Step 3. Create a project and plan
- Step 4. Configure tasks
- Get feedback

Related pages:

- Getting started with .NET and Bamboo
- Getting started with Ruby and Bamboo

Information you need before you begin

This introduction assumes you are using Bamboo Server installed on your local network. You need to make sure you or your company administrator have properly installed and configured Bamboo for running plans.

You will also need to install:

- The PHP framework
- PHPUnit testing framework

Step 1: Install the PHP base code framework

In order to get full functionality from Bamboo and PHP, you will need to install the PHP base code framework. If you are using Ubuntu, then use the following command to install PHP.

```bash
$ sudo apt-get install php5-cli
```

See also:

- Installing PHP on MacOS
- Installing PHP on Windows

Step 2: Install PHPUnit
PHPUnit.de provides an excellent PHP archive resource called PHAR.

```bash
$ wget https://phar.phpunit.de/phpunit.phar  // download the PHPUnit packages
$ chmod +x phpunit.phar  // make PHPUnit executable
$ mv phpunit.phar /usr/local/bin/phpunit  // copy PHPUnit into your path
$ phpunit --version  // double check it's installed completely
```

If you prefer, you may use Composer or PEAR to download and install PHPUnit along with its dependencies, however these approaches are beyond the scope of this introduction.

---

Step 3. Create a project and plan

1. **Create a new project**

A Bamboo plan defines the details of your continuous integration workflow. You use a plan to identify the source code repository, specify the tasks to run in your build, and when to trigger a build. Each plan belongs to a project. You can add a plan to an existing project or create a new project. In this example, you create both a new project and a new plan in that project.

   1. Log into your Bamboo instance as a user with permissions to create plans.
   2. Choose Create > Create a New Plan from the menu bar.

   Every plan belongs to a project. We don't have a project yet, so choose Project > New Project, and enter details for both the project and plan.

   ![Project creation](image)

   **Project**
   - New Project
   - **Project Name**: TestProject
   - **Project Key**: TP

2. **Configure the plan details**

Bamboo needs to know the Plan name, Plan key and a brief description of what the plan is for. See Configuring plans for more details.

   ![Plan details](image)

   **Plan name**
   - Tutorials

   **Plan key**
   - TUT

   **Description**
   - Build atlassian tutorials
Build Atlassian tutorials

3. Choose a source repository

Bamboo needs to know where the source code repository is located, and needs access to the repo so that it can check out the code when it runs a build. See Linking to source code repositories for more details.

![Source repositories](image)

Source Repository

Bitbucket

**Username**

Your Bitbucket username

**Password**

Your Bitbucket password

**Repository**

atlassian_tutorial/hellworld (git)

**Branch**

master

**Use shallow clones**

Set this checkbox

4. Triggering the build

We can choose how Bamboo gets triggered to run the plan build:

![Trigger](image)

**Trigger type**

Repository triggers the build when changes are committed

**Trigger IP**

Optionally add an IP address for your repository

See Triggering builds for more details.

Step 4. Configure tasks

Each plan needs to have at least one task specified. Tasks do the real work of the plan.

*The source code checkout task*
A newly created plan has a default Source Code Checkout task that gets the source code from the source repository specified earlier. See Checking out code for details.

Unit testing

Unit testing for PHP is completed using the PHPUnit testing framework. This is a port of the popular Java JUnit testing framework to PHP. PHPUnit provides also produces test results in the JUnit XML format required by Bamboo.

You will need to add a server executable capability to run PHPUnit:

1. Go to Overview > Server capabilities.
2. Click Add capability and complete the configuration using the following:
   
   **Capability type**
   Executable
   
   **Type**
   PHPUnit
   
   **Executable label**
   PHPUnit x.x
   
   **Path**
   Path to the PHPUnit executable e.g. /usr/bin/phpunit-x.x
3. Click Add to add the PHPUnit capability.

Now you can create a PHPUnit testing task:

Getting the test results
Your tests will be run when the builder task compiles the code. Each of the builder tasks above has a section to tell Bamboo to expect test results and where to look for them. You can specify a custom results location if your project directory doesn’t use the conventional structure.

<table>
<thead>
<tr>
<th>Where should Bamboo look for the test result files?</th>
</tr>
</thead>
<tbody>
<tr>
<td>✔️ The build will produce test results.</td>
</tr>
<tr>
<td>If checked, the build will fail if no tests are found. Test output must be in JUnit XML format.</td>
</tr>
<tr>
<td>Test Results Directory</td>
</tr>
<tr>
<td>Look in the standard test results directory.</td>
</tr>
<tr>
<td>Specify custom results directories</td>
</tr>
<tr>
<td>Where should Bamboo look for the test result files?</td>
</tr>
</tbody>
</table>

See Jobs and tasks for details.

**Step 5: Go!**

Enable the plan, and click Create.

You should see the plan run. The ‘Plan Summary’ tab will report whether the build succeeded or not.

Tests in the appropriate directory in the source code repository will be run automatically as part of the build, and the test results will be displayed in Bamboo.

Now, whenever you commit a change to the repository, Bamboo will build your source code and report on your test results.

Get feedback

Bamboo displays a summary of the results of the build on the dashboard.

You can get further information about the build in the following ways:

- Build results for one or more plans can be displayed on a wallboard.
- You can get notifications about build results sent to you by email, IM and RSS feed.
- You can get build statistics about plans, and about developers contributing code to the build.
- You can drill down into the results to see the code changes that triggered the build, and the tests that were run for that build.

See Getting feedback for details.

---

**Information you need before you begin**

This introduction assumes you are using Bamboo Server installed on your local network. You need to make sure you or your company administrator have properly installed and configured Bamboo for running plans.

You will also need to install:

- The PHP framework
- PHPUnit testing framework
Step 1: Install the PHP base code framework

In order to get full functionality from Bamboo and PHP, you will need to install the PHP base code framework. If you are using Ubuntu, then use the following command to install PHP.

```
$ sudo apt-get install php5-cli
```

See also:

- Installing PHP on MacOS
- Installing PHP on Windows

Step 2: Install PHPUnit

PHPUnit.de provides an excellent PHP archive resource called PHAR.

```
$ wget https://phar.phpunit.de/phpunit.phar  // download the PHPUnit packages
$ chmod +x phpunit.phar  // make PHPUnit executable
$ mv phpunit.phar /usr/local/bin/phpunit  // copy PHPUnit into your path
$ phpunit --version  // double check it's installed completely
```

If you prefer, you may use Composer or PEAR to download and install PHPUnit along with its dependencies, however these approaches are beyond the scope of this introduction.

Step 3. Create a project and plan

1. Create a new project

A Bamboo plan defines the details of your continuous integration workflow. You use a plan to identify the source code repository, specify the tasks to run in your build, and when to trigger a build. Each plan belongs to a project. You can add a plan to an existing project or create a new project. In this example, you create both a new project and a new plan in that project.

   1. Log into your Bamboo instance as a user with permissions to create plans.
   2. Choose Create > Create a New Plan from the menu bar.

Every plan belongs to a project. We don't have a project yet, so choose Project > New Project, and enter details for both the project and plan.

![Project](image)

Project

New Project

Project Name

TestProject

Project Key

TP

2. Configure the plan details

Bamboo needs to know the Plan name, Plan key and a brief description of what the plan is for. See Configuring plans for more details.
Plan details

Plan name: Tutorials
Plan key: TUT
Description: Build Atlassian tutorials

3. Choose a source repository

Bamboo needs to know where the source code repository is located, and needs access to the repo so that it can check out the code when it runs a build. See Linking to source code repositories for more details.

Source repositories

Source repository: Bitbucket
Username: Your Bitbucket username
Password: Your Bitbucket password
Repository: atlassian_tutorial/hellworld (git)
Branch: master
Use shallow clones: Set this checkbox

4. Triggering the build

We can choose how Bamboo gets triggered to run the plan build:
Trigger type

Repository triggers the build when changes are committed

Trigger IP

Optionally add an IP address for your repository

See Triggering builds for more details.

Step 4. Configure tasks

Each plan needs to have at least one task specified. Tasks do the real work of the plan.

The source code checkout task

A newly created plan has a default Source Code Checkout task that gets the source code from the source repository specified earlier.

See Checking out code for details.

Unit testing

Unit testing for PHP is completed using the PHPUnit testing framework. This is a port of the popular Java JUnit testing framework to PHP. PHPUnit provides also produces test results in the JUnit XML format required by Bamboo.

You will need to add a server executable capability to run PHPUnit:

1. Go to Overview > Server capabilities.
2. Click Add capability and complete the configuration using the following:

   Capability type
   Executable

   Type
   PHPUnit

   Executable label
   PHPUnit x.x

   Path
   Path to the PHPUnit executable e.g. /usr/bin/phpunit-x.x
3. Click Add to add the PHPUnit capability.

Now you can create a PHPUnit testing task:
Getting the test results

Your tests will be run when the builder task compiles the code. Each of the builder tasks above has a section to tell Bamboo to expect test results and where to look for them. You can specify a custom results location if your project directory doesn't use the conventional structure.

See Jobs and tasks for details.

Step 5: Go!

Enable the plan, and click Create.

You should see the plan run. The 'Plan Summary' tab will report whether the build succeeded or not.

Tests in the appropriate directory in the source code repository will be run automatically as part of the build, and the test results will be displayed in Bamboo.

Now, whenever you commit a change to the repository, Bamboo will build your source code and report on your test results.

Get feedback
Bamboo displays a summary of the results of the build on the dashboard.

You can get further information about the build in the following ways:

- Build results for one or more plans can be displayed on a wallboard.
- You can get notifications about build results sent to you by email, IM and RSS feed.
- You can get build statistics about plans, and about developers contributing code to the build.
- You can drill down into the results to see the code changes that triggered the build, and the tests that were run for that build.

See [Getting feedback](#) for details.

### Getting started with Ruby and Bamboo

#### Getting started with Ruby and Bamboo v5.14

#### Getting started with Ruby and Bamboo v6.2

#### Getting started with Ruby and Bamboo v6.3

### Using the Bamboo dashboard

The dashboard is your Bamboo 'home' page. The dashboard has three tabs:

- **My Bamboo** — a convenient summary of information that is relevant to you (only appears if you have logged in to Bamboo):
  - plans that you have nominated as your favorites
  - your latest build results (i.e. builds that were triggered by your latest code changes)
  - a summary of your build statistics (only appear if your Bamboo User Profile has been associated with your Author Name).

- **All build plans** — a list of plans and each plan's latest build result.
- **Build Activity** — Bamboo's agents and build queue, showing which plans Bamboo is currently building and which plans are waiting to be built.

You can return to the dashboard from anywhere in Bamboo by clicking [Dashboard](#) in the top navigation menu.

**On this page:**
- Viewing the dashboard
- Filtering the plans
- Working with favorites

**Related pages:**
- Configuring plans
- Working with builds
- Getting feedback

### Viewing the dashboard

You can:

- click the **project name** (e.g. 'Bamboo Testing') to view the plans in the project.
- click the **plan name** (e.g. 'Acceptance Test JDK 1.6') to view the plan details.
- click the **build number** (e.g. '7823') to view the build result.
- click the **author's name** to view the author's details (the author is the person who triggered the build by checking-in code).

The icon next to a build number indicates the plan's current status:

- ✓ This plan's latest build was successful.
- 🟡 This plan's latest build failed.
- 🛠 Bamboo is currently checking-out the source-code for this plan, in preparation for starting a build.
- 💡 Bamboo is currently queuing a build for this plan in the Build Queue.
- ⚙ Bamboo is currently executing a build for this plan.
- 🕒 The plan is stopped at a manual stage.
The plan was not built, perhaps because the build was manually stopped.

This plan has been disabled.

Screenshot: Bamboo dashboard - ‘All Plans’ tab

Filtering the plans

You can filter the plans on your dashboard according to plan labels. For instructions on how to add a label to a plan, see Working with labels.

To filter the dashboard plans by label:

1. Navigate to the dashboard.
2. Click the button. If the plan already has labels, they will be displayed next to the button, otherwise the button will read Filter Plans.
3. In the ‘Filter Plans’ dialog, select the labels to filter by.
4. Click Save. The dashboard will refresh, showing only the plans with the selected labels.

Screenshot: Filtering plans on a dashboard

Working with favorites

The My Bamboo tab lists your favorite plans — that is, the plans you work with the most. You can easily add and remove plans from your
When you add a plan to your favorites, you become a ‘watcher’ of the plan. This means that you will receive notifications about the build results for your favorite plans, depending on how your administrator has configured each plan's notifications. You can receive notifications by email, Instant Messaging (IM) and RSS feed.

**To add a plan to your favorites:**

1. Click Dashboard in the top navigation bar, to display the dashboard.
2. Click the All Plans tab. This will display a list of all plans in your Bamboo system.
3. Locate the plan and click the grey star icon at the right.

**Viewing Bamboo’s agents**

A Bamboo agent is a service that can run job builds. There are the following types of Bamboo agents:

- **local agents** run as part of the Bamboo server.
- **remote agents** run on computers, other than the Bamboo server, that run the remote agent tool.
- **elastic agents** run in the Amazon Elastic Compute Cloud (EC2).

Local agents run in the Bamboo server's process, i.e. in the same JVM as the server. Each remote agent runs in its own process, i.e. has its own JVM.

Each agent has a defined set of capabilities and can only run builds for jobs whose requirements match the agent's capabilities.

**To view agents that are currently active, see Using the Bamboo dashboard.**

**View the agents in Bamboo**

1. Choose Build > Build activity from the Bamboo header.
2. Click the name of the agent in the 'Building' section to see details for that particular agent.
3. Click X of Y online agents building in the 'Building' section of the page to see a list of all available agents.

**View a specific Bamboo agent as a Bamboo administrator**

1. Choose Agents from the 'cog' menu of the Bamboo header.
2. Click the name of the agent. You can configure this agent and its capabilities:
   - Click Executable Plans to view the plans that this agent can build.
   - Click System Properties to view the system properties of this agent.

**Using the Bamboo dashboard v5.14**

The dashboard is your Bamboo 'home' page. The dashboard has three tabs:

- **My Bamboo** — a convenient summary of information that is relevant to you (only appears if you have logged in to Bamboo):
  - plans that you have nominated as your favorites.
  - your latest build results (i.e. builds that were triggered by your latest code changes).
  - a summary of your build statistics (only appear if your Bamboo User Profile has been associated with your Author Name).

- **All build plans** — a list of plans and each plan's latest build result.
- **Build Activity** — Bamboo's agents and build queue, showing which plans Bamboo is currently building and which plans are waiting to be built.

You can return to the dashboard from anywhere in Bamboo by clicking Dashboard in the top navigation menu.
- click the plan name (e.g. 'Acceptance Test JDK 1.6') to view the plan details.
- click the build number (e.g. '7823') to view the build result.
- click the author's name to view the author's details (the author is the person who triggered the build by checking-in code).

The icon next to a build number indicates the plan's current status:

- This plan's latest build was successful.
- This plan's latest build failed.
- Bamboo is currently checking-out the source-code for this plan, in preparation for starting a build.
- Bamboo is currently queuing a build for this plan in the Build Queue.
- Bamboo is currently executing a build for this plan.
- The plan is stopped at a manual stage.
- The plan was not built, perhaps because the build was manually stopped.
- This plan has been disabled.

**Screenshot: Bamboo dashboard - 'All Plans' tab**

Getting started with Node.js and Bamboo

Node.js is described as:

"a platform built on Chrome's JavaScript engine for easily building fast, scalable network applications. Node.js uses an event-driven, non-blocking I/O model that makes it lightweight and efficient, perfect for data-intensive real-time applications that run across distributed devices." [Node.js](https://nodejs.org)

We agree, and bundle a number of tasks with Bamboo to make it easy for you to get continuous integration and deployment for your Node.js projects. You can find the official Node.js documentation [here](https://nodejs.org).

Distributions

Node.js distributions usually come bundled with npm, a package manager for the platform, which runs from the command line and manages dependencies for your applications.
All npm packages contain a file, usually in the project root, called `package.json` - this file holds metadata relevant to the project. You can find out more about the package.json file here.

Configure your Node.js project

Add the following dependencies (or devDependencies) to the `package.json` file in your Node.js project. These are required if you want to use the Grunt, Gulp, Bower, Nodeunit or Mocha Test Runner tasks:

**Grunt**
- `grunt` (v0.4 or newer)
- `grunt-cli`

**Gulp**
- `gulp` (v3.3.2 or newer recommended)

**Bower**
- `bower`

**Mocha Test Runner**
- `mocha`
- `mocha-bamboo-reporter`

**Nodeunit**
- `nodeunit`

Your package.json file should look something like this:

```json
...
"devDependencies": {
  ...
  "mocha": "~1.18",
  "mocha-bamboo-reporter": "*",
  ...
  "nodeunit": "~0.8"
}
"dependencies": {
  ...
  "grunt": "~0.4",
  "grunt-cli": "~0.1",
  ...
  "gulp": "~3.3.2",
  ...
  "bower": "~1.3.12"
}
```

Install the necessary `node_modules` before executing any of the Node.js tasks, by adding an `npm` task and using the `install` command.

Node.js tasks

Bamboo ships with specific tasks for Node.js that make it easy to integrate the Node.js platform with Bamboo. You can use these tasks to set up builds for your Node.js project.
Note that it is possible to execute scripts installed by the npm task from the node_modules; however, we recommend that you use the dedicated tasks for executing such scripts, such as Grunt, Mocha or Nodeunit.

Install the necessary node_modules before executing any of the Node.js tasks, by adding an npm task and using the install command.

**npm task**

The npm task allows you to execute Node Package Manager commands in build plans and deployment projects. To run npm commands, simply enter the command to execute during task configuration:

In order to execute npm commands, the Node.js capability must be present on your build agent (see below).

Note: since Node.js and npm are distributed together, Bamboo will use the Node.js capability for npm tasks as well. The path will be modified at run time to point to the npm executable.

**Node.js task**

The Node.js task is a general purpose task that can be used to execute Node scripts within Bamboo.
To run the Node.js task, the Node.js capability must be present on your local or remote agents (see below).

Node.js can be used to execute any custom Node.js scripts or applications. To do so, enter the path of the script to execute in the task configuration, and optionally define additional arguments to pass.

Note that it is possible to execute scripts installed by the `npm` task from the `node_modules`, however we recommend that you use the dedicated tasks for executing such scripts, such as Grunt, Mocha or Nodeunit.

Mocha

Mocha is a test framework that runs on the Node.js platform.

You can use the Mocha Test Runner task to run your Mocha tests – it will create an output file named `mocha.json`.

You can configure the task to parse test results after a successful execution. Alternatively, you can add a Mocha Test Parser task to run afterwards to parse the test results.

If you don't do a full checkout on each build, make sure you add a task to delete `mocha.json` before the Mocha Test Runner task. A simple script task that runs `rm -f mocha.json` should do the trick.

Grunt

Use the Grunt task to take advantage of the Grunt task runner.

Nodeunit

Nodeunit is a tool for defining and running unit tests for Node.js projects.

Running the Nodeunit task will create test results in JUnit XML format.

You can configure the task to parse test results after a successful execution. Alternatively, you can add a following JUnit Parser task to parse the test results.

Node.js capability

Bamboo comes with a definition for a new executable capability called Node.js. In order to use the Node.js task (as well as most of the other Node.js tasks in Bamboo), you need this capability to be present on your local or remote agents.

The capability can be auto detected on the server side.
The `NODE_HOME` environment variable will instruct Bamboo where to look for Node.js if it is not installed in a typical directory - it should point to the location of the Node.js installation. Bamboo will search the agent’s default directories to find the Node.js installation; it will also search in location specified by `NODE_HOME`.

### .Getting started with Node.js and Bamboo v5.14

Node.js is described as:

>a platform built on Chrome's JavaScript engine for easily building fast, scalable network applications. Node.js uses an event-driven, non-blocking I/O model that makes it lightweight and efficient, perfect for data-intensive real-time applications that run across distributed devices." [Node.js](https://nodejs.org)

We agree, and bundle a number of tasks with Bamboo to make it easy for you to get continuous integration and deployment for your Node.js projects. You can find the official Node.js documentation [here](https://nodejs.org).

### Distributions

Node.js distributions usually come bundled with npm, a package manager for the platform, which runs from the command line and manages dependencies for your applications.

All npm packages contain a file, usually in the project root, called `package.json` - this file holds metadata relevant to the project. You can find out more about the `package.json` file [here](https://docs.npmjs.com/Package-JSON).

### Configure your Node.js project

Add the following dependencies (or devDependencies) to the `package.json` file in your Node.js project. These are required if you want to use the Grunt 0.4.x, Gulp, Bower, Nodeunit or Mocha Test Runner tasks:

<table>
<thead>
<tr>
<th>Grunt 0.4.x</th>
<th>Gulp</th>
<th>Bower</th>
<th>Mocha Test Runner</th>
<th>Nodeunit</th>
</tr>
</thead>
<tbody>
<tr>
<td>• grunt (v0.4 or newer)</td>
<td>• gulp (v3.3.2 or newer recommended)</td>
<td>• bower</td>
<td>• mocha</td>
<td>• mocha-bamboo-reporter</td>
</tr>
<tr>
<td>• grunt-cli</td>
<td></td>
<td></td>
<td>• mocha</td>
<td></td>
</tr>
</tbody>
</table>

Your `package.json` file should look something like this:
Install the necessary node modules before executing any of the Node.js tasks, by adding an npm task and using the install command.

Node.js tasks

Bamboo ships with specific tasks for Node.js that make it easy to integrate the Node.js platform with Bamboo. You can use these tasks to set up builds for your Node.js project.

Note that it is possible to execute scripts installed by the npm task from the node_modules; however, we recommend that you use the dedicated tasks for executing such scripts, such as Grunt, Mocha or Nodeunit.

Install the necessary node modules before executing any of the Node.js tasks, by adding an npm task and using the install command.

npm task

The npm task allows you to execute Node Package Manager commands in build plans and deployment projects. To run npm commands, simply enter the command to execute during task configuration:
In order to execute npm commands, the Node.js capability must be present on your build agent (see below).

Note: since Node.js and npm are distributed together, Bamboo will use the Node.js capability for npm tasks as well. The path will be modified at run time to point to the npm executable.

**Node.js task**

The Node.js task is a general purpose task that can be used to execute Node scripts within Bamboo.

To run the Node.js task, the Node.js capability must be present on your local or remote agents (see below).

Node.js can be used to execute any custom Node.js scripts or applications. To do so, enter the path of the script to execute in the task configuration, and optionally define additional arguments to pass.

Note that it is possible to execute scripts installed by the npm task from the node_modules, however we recommend that you use the dedicated tasks for executing such scripts, such as Grunt, Mocha or Nodeunit.

**Mocha**

Mocha is a test framework that runs on the Node.js platform.

You can use the Mocha Test Runner task to run your Mocha tests – it will create an output file named `mocha.json`.

You can configure the task to parse test results after a successful execution. Alternatively, you can add a Mocha Test Parser task to run afterwards to parse the test results.

If you don’t do a full checkout on each build, make sure you add a task to delete `mocha.json` before the Mocha Test Runner task. A simple script task that runs `rm -f mocha.json` should do the trick.

**Grunt**

Use the Grunt task to take advantage of the Grunt task runner.
**Nodeunit**

Nodeunit is a tool for defining and running unit tests for Node.js projects.

Running the Nodeunit task will create test results in JUnit XML format.

You can configure the task to parse test results after a successful execution. Alternatively, you can add a following JUnit Parser task to parse the test results.

**Node.js capability**

Bamboo comes with a definition for a new executable capability called Node.js. In order to use the Node.js task (as well as most of the other Node.js tasks in Bamboo), you need this capability to be present on your local or remote agents.

The capability can be auto detected on the server side.

**Server capabilities**

You can use this page to view, add and delete server capabilities. These capabilities will be inherited by all local agents.

**Executable**

<table>
<thead>
<tr>
<th>Executable</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ant (Ant)</td>
<td>/usr/share/ant</td>
</tr>
<tr>
<td>Grails (Grails)</td>
<td>/usr/share/grails/2.2.0</td>
</tr>
<tr>
<td>Node.js (Node.js)</td>
<td>/opt/node-v0.10.26-linux-x64/bin/node</td>
</tr>
</tbody>
</table>

**JDK**

JDK capabilities define the JDKs which are available to your build plans.

<table>
<thead>
<tr>
<th>JDK label</th>
<th>Java home</th>
</tr>
</thead>
<tbody>
<tr>
<td>JDK</td>
<td>/usr/lib/jvm/jdk1.6.0_45</td>
</tr>
<tr>
<td>JDK 1.6</td>
<td>/usr/lib/jvm/jdk1.6.0_45</td>
</tr>
<tr>
<td>JDK 1.6.0_45</td>
<td>/usr/lib/jvm/jdk1.6.0_45</td>
</tr>
</tbody>
</table>

The `NODE_HOME` environment variable will instruct Bamboo where to look for Node.js if it is not installed in a typical directory - it should point to the location of the Node.js installation. Bamboo will search the agent's default directories to find the Node.js installation; it will also search in location specified by `NODE_HOME`.

**.Getting started with Node.js and Bamboo v6.0**

Node.js is described as:

> "a platform built on Chrome's JavaScript engine for easily building fast, scalable network applications. Node.js uses an event-driven, non-blocking I/O model that makes it lightweight and efficient, perfect for data-intensive real-time applications that run across distributed devices."

Node.js

We agree, and bundle a number of tasks with Bamboo to make it easy for you to get continuous integration and deployment for your Node.js projects. You can find the official Node.js documentation here.

**Distributions**

Node.js distributions usually come bundled with npm, a package manager for the platform, which runs from the command line and manages dependencies for your applications.

All npm packages contain a file, usually in the project root, called `package.json` - this file holds metadata relevant to the project. You can find out more about the `package.json` file here.

**Configure your Node.js project**

Add the following dependencies (or devDependencies) to the `package.json` file in your Node.js project. These are required if you want to use the Grunt, Gulp, Bower, Nodeunit or Mocha Test Runner tasks:

<table>
<thead>
<tr>
<th>Grunt</th>
<th>grunt (v0.4 or newer)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gulp</td>
<td>gulp (v3.3.2 or newer recommended)</td>
</tr>
<tr>
<td>Bower</td>
<td>bower</td>
</tr>
</tbody>
</table>
Your package.json file should look something like this:

```json
...
"devDependencies": {
  ...
  "mocha": "~1.18",
  "mocha-bamboo-reporter": "*",
  ...
  "nodeunit": "~0.8"
}
"dependencies": {
  ...
  "grunt": "~0.4",
  "grunt-cli": "~0.1",
  ...
  "gulp": "~3.3.2",
  ...
  "bower": "~1.3.12"
}
```

Install the necessary `node_modules` before executing any of the Node.js tasks, by adding an `npm` task and using the `install` command.

### Node.js tasks

Bamboo ships with specific tasks for Node.js that make it easy to integrate the Node.js platform with Bamboo. You can use these tasks to set up builds for your Node.js project.

**Task types**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>node@</code></td>
<td>Execute javascript on the server with Node.js</td>
</tr>
<tr>
<td><code>npm</code></td>
<td>npm package manager for Node.js</td>
</tr>
<tr>
<td><code>Mocha Test Runner</code></td>
<td>Run Mocha tests using <code>mocha-bamboo-reporter</code></td>
</tr>
<tr>
<td><code>Grunt 0.4.x</code></td>
<td>Execute Grunt 0.4 task</td>
</tr>
<tr>
<td><code>Nodeunit</code></td>
<td>Execute Nodeunit tests producing results in JUnit XML format</td>
</tr>
</tbody>
</table>

Note that it is possible to execute scripts installed by the `npm` task from the `node_modules`; however, we recommend that you use the dedicated tasks for executing such scripts, such as Grunt, Mocha or Nodeunit.

Install the necessary `node_modules` before executing any of the Node.js tasks, by adding an `npm` task and using the `install` command.

**npm task**

The `npm` task allows you to execute Node Package Manager commands in build plans and deployment projects. To run `npm` commands,
simply enter the command to execute during task configuration:

In order to execute npm commands, the Node.js capability must be present on your build agent (see below).

Note: since Node.js and npm are distributed together, Bamboo will use the Node.js capability for npm tasks as well. The path will be modified at run time to point to the npm executable.

Node.js task

The Node.js task is a general purpose task that can be used to execute Node scripts within Bamboo.

To run the Node.js task, the Node.js capability must be present on your local or remote agents (see below).

Node.js can be used to execute any custom Node.js scripts or applications. To do so, enter the path of the script to execute in the task configuration, and optionally define additional arguments to pass.

Note that it is possible to execute scripts installed by the npm task from the node_modules, however we recommend that you use the dedicated tasks for executing such scripts, such as Grunt, Mocha or Nodeunit.

Mocha

Mocha is a test framework that runs on the Node.js platform.

You can use the Mocha Test Runner task to run your Mocha tests – it will create an output file named mocha.json.

You can configure the task to parse test results after a successful execution. Alternatively, you can add a Mocha Test Parser task to run afterwards to parse the test results.

If you don’t do a full checkout on each build, make sure you add a task to delete mocha.json before the Mocha Test Runner task. A simple script task that runs `rm -f mocha.json` should do the trick.

Grunt
Use the Grunt task to take advantage of the Grunt task runner.

**Nodeunit**

Nodeunit is a tool for defining and running unit tests for Node.js projects.

Running the Nodeunit task will create test results in JUnit XML format.

You can configure the task to parse test results after a successful execution. Alternatively, you can add a following JUnit Parser task to parse the test results.

**Node.js capability**

Bamboo comes with a definition for a new executable capability called Node.js. In order to use the Node.js task (as well as most of the other Node.js tasks in Bamboo), you need this capability to be present on your local or remote agents.

The capability can be auto detected on the server side.

### Distributions

The capability can be auto detected on the server side.

### Server capabilities

You can use this page to view, add and delete server capabilities. These capabilities will be inherited by all local agents.

#### Executable

Executable capabilities define the executables which are available to your build plans.

<table>
<thead>
<tr>
<th>Executable label</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ant (Ant)</td>
<td>/usr/share/ant</td>
</tr>
<tr>
<td>Grails (Grails)</td>
<td>/usr/share/grails/2.2.0</td>
</tr>
<tr>
<td>Node.js (Node.js)</td>
<td>/opt/node-v0.10.28-linux-x64/bin/node</td>
</tr>
</tbody>
</table>

#### JDK

JDK capabilities define the JDKs which are available to your build plans.

<table>
<thead>
<tr>
<th>JDK label</th>
<th>Java home</th>
</tr>
</thead>
<tbody>
<tr>
<td>JDK</td>
<td>/usr/lib/jvm/jdk1.6.0_45</td>
</tr>
<tr>
<td>JDK 1.8</td>
<td>/usr/lib/jvm/jdk1.6.0_45</td>
</tr>
<tr>
<td>JDK 1.6.0</td>
<td>/usr/lib/jvm/jdk1.6.0_45</td>
</tr>
<tr>
<td>JDK 1.6.0</td>
<td>/usr/lib/jvm/jdk1.6.0_45</td>
</tr>
</tbody>
</table>

The `NODE_HOME` environment variable will instruct Bamboo where to look for Node.js if it is not installed in a typical directory - it should point to the location of the Node.js installation. Bamboo will search the agent's default directories to find the Node.js installation; it will also search in location specified by `NODE_HOME`.

**Getting started with Docker and Bamboo**

Manage and run your Bamboo remote agents using Docker.

A Bamboo server can use one or more remote build agents (up to 1000 depending on your license). Remote agents execute jobs from your build plan. Because jobs can have different requirements, it is useful to have agents with different capabilities.

Docker is a great way to manage your remote agents, and provides:

- Ease of use – you can automate or script the creation and maintenance of your remote agents.
- Very quick duplication and distribution of changes to remote agents.
- The ability to run multiple remote agents on the same host without conflicting requirements.

Read Configuring the Docker task in Bamboo to see how you can build Docker images, run Docker containers as part of your Bamboo build, and push a Docker image to a Docker registry.

**Docker images**

Atlassian has published two images to the Docker Hub at https://hub.docker.com/u/atlassian/.

You can modify these images to suit your own requirements.

**atlassian/bamboo-java-agent**

Suitable for java stack development.
Bamboo agent .jar (5.6.0)  
OpenJDK 7  
GIT, Mercurial, CVS and SVN  
Maven 2, 3 and Ant

\texttt{atlassian/bamboo-base-agent}  
Suitable for deep customization.

- Bamboo agent .jar (5.6.0)  
- OpenJDK 7

\textbf{Bamboo server}  
Note that the Docker images do not include a Bamboo server. Download and install Bamboo separately before continuing – see \textit{Getting started with Bamboo}.

\textbf{Usage}  
For a new Bamboo installation there will not be any remote agents yet. When you run a remote agent (see below), it will connect to the Bamboo server and will be ready to execute jobs from your build plans.

Ensure your Bamboo server is running, then go to \textit{Administration > Agents} to see your remote agent once it is running.

The following commands need to be run with \texttt{sudo} because Docker needs to run as root. You may need to replace \texttt{docker} with \texttt{docker.io} (depending on your installation) – see \url{http://docker.io}.

Pull the remote build agent from the Docker Hub Repository:

\begin{verbatim}
  sudo docker pull atlassian/bamboo-java-agent
\end{verbatim}

Once downloaded, run your agent with the following command:

\begin{verbatim}
  sudo docker run -e HOME=/root/ -e BAMBOO_SERVER=http://hostname:port/bamboo -i -t atlassian/bamboo-java-agent:latest
\end{verbatim}

Replace \texttt{hostname:port} with your Bamboo server's name and port (typically 8085).  
Don't use \texttt{localhost} as the server address because for Docker, \texttt{localhost} is in the Docker container, not the host machine.

Go back to \textit{Administration > Agents} (or refresh that page) and notice that your remote agent has registered itself.

\textbf{Customization}  
The two Bamboo agent images are based on our own \texttt{atlassian/ubuntu-minimal} image, which is built using the Docker 'contrib' script and 'debootstrap'.

To customize an image, run it in a container. Name the container for easier access later:

\begin{verbatim}
  sudo docker run --name="tmp-name" -e HOME=/root/ -i -t atlassian/bamboo-java-agent:latest /bin/bash
\end{verbatim}

Now change whatever you want inside the container with the usual bash commands. You can enforce some capabilities by changing the file at \texttt{/root/bamboo-agent-home/bin/bamboo-capabilities.properties}.

After that, exit and create a new image from the container like this:
```bash
sudo docker commit tmp-name atlassian/customized-agent:1.0.0
```

You can publish your new image by pushing it to the Docker Registry.

### Troubleshooting

If you have DNS problems (i.e. the Docker container can ping the IP of the server but not the hostname) consider using this command:

```bash
sudo docker run --dns=your-dns-server-ip1 --dns=your-dns-server-ip2
```

You’ll need to replace those values with the actual IP addresses of your DNS server.

If the agent seems to connect and start bootstrapping but has trouble with active mq then check on your Bamboo server that you have set up the broker URL correctly. Go to Administration > General configuration. You should not have ‘localhost’ specified there.

### Getting started with Docker and Bamboo v5.14

Manage and run your Bamboo remote agents using Docker!

A Bamboo server can use one or more remote build agents (up to 100 depending on your license). Remote agents execute jobs from your build plan. Because jobs can have different requirements, it is useful to have agents with different capabilities.

Docker is a great way to manage your remote agents, and provides:

- Ease of use – you can automate or script the creation and maintenance of your remote agents.
- Very quick duplication and distribution of changes to remote agents.
- The ability to run multiple remote agents on the same host without conflicting requirements.

Read Configuring the Docker task in Bamboo to see how you can build Docker images, run Docker containers as part of your Bamboo build, and push a Docker image to a Docker registry.

### Docker images

Atlassian has published two images to the Docker Hub at https://hub.docker.com/u/atlassian/:

<table>
<thead>
<tr>
<th>Image Name</th>
<th>Description</th>
<th>Requirements</th>
</tr>
</thead>
</table>
| atlassian/bamboo-java-agent         | Suitable for java stack development. | - Bamboo agent .jar (5.6.0)  
- OpenJDK 7  
- GIT, Mercurial, CVS and SVN  
- Maven 2, 3 and Ant |
| atlassian/bamboo-base-agent         | Suitable for deep customization. | - Bamboo agent .jar (5.6.0)  
- OpenJDK 7 |

You can modify these images to suit your own requirements.

### Bamboo server

Note that the Docker images do not include a Bamboo server. Download and install Bamboo separately before continuing – see Getting started with Bamboo.

### Usage

For a new Bamboo installation there will not be any remote agents yet. When you run a remote agent (see below), it will connect to the Bamboo server and will be ready to execute jobs from your build plans.

Ensure your Bamboo server is running, then go to Administration > Agents to see your remote agent once it is running.

The following commands need to be run with sudo because Docker needs to run as root. You may need to replace docker with docker.io (depending on your installation) – see http://docker.io.

Pull the remote build agent from the Docker Hub Repository:
sudo docker pull atlassian/bamboo-java-agent

Once downloaded, run your agent with the following command:

```bash
sudo docker run -e HOME=/root/ -e BAMBOO_SERVER=http://hostname:port/bamboo -i -t atlassian/bamboo-java-agent:latest
```

Replace `hostname:port` with your Bamboo server’s name and port (typically 8085).

Don’t use `localhost` as the server address because for Docker, `localhost` is in the Docker container, not the host machine.

Go back to Administration > Agents (or refresh that page) and notice that your remote agent has registered itself.

**Customization**

The two Bamboo agent images are based on our own atlassian/ubuntu-minimal image, which is built using the Docker ‘contrib’ script and ‘debootstrap’.

To customize an image, run it in a container. Name the container for easier access later:

```bash
sudo docker run --name="tmp-name" -e HOME=/root/ -i -t atlassian/bamboo-java-agent:latest /bin/bash
```

Now change whatever you want inside the container with the usual bash commands. You can enforce some capabilities by changing the file in `/root/bamboo-agent-home/bin/bamboo-capabilities.properties`.

After that, exit and create a new image from the container like this:

```bash
sudo docker commit tmp-name atlassian/customized-agent:1.0.0
```

You can publish your new image by pushing it to the Docker Registry.

**Troubleshooting**

If you have DNS problems (i.e. the Docker container can ping the IP of the server but not the hostname) consider using this command:

```bash
sudo docker run --dns=your-dns-server-ip1 --dns=your-dns-server-ip2
```

You’ll need to replace those values with the actual IP addresses of your DNS server.

If the agent seems to connect and start bootstrapping but has trouble with active mq then check on your Bamboo server that you have set up the broker URL correctly. Go to Administration > General configuration. You should not have ‘localhost’ specified there.

**Getting started with Docker and Bamboo v6.1**

Manage and run your Bamboo remote agents using Docker!

A Bamboo server can use one or more remote build agents (up to 100 depending on your license). Remote agents execute jobs from your build plan. Because jobs can have different requirements, it is useful to have agents with different capabilities.

Docker is a great way to manage your remote agents, and provides:

- Ease of use – you can automate or script the creation and maintenance of your remote agents.
- Very quick duplication and distribution of changes to remote agents.

**atlassian/bamboo-java-agent**

Suitable for java stack development.

- Bamboo agent .jar (5.6.0)
- OpenJDK 7
- GIT, Mercurial, CVS and SVN
- Maven 2, 3 and Ant

**atlassian/bamboo-base-agent**

Suitable for deep customization.

- Bamboo agent .jar (5.6.0)
- OpenJDK 7

Bamboo server

Note that the Docker images do not include a Bamboo server. Download and install Bamboo separately before continuing – see Getting started with Bamboo.

Usage

For a new Bamboo installation there will not be any remote agents yet. When you run a remote agent (see below), it will connect to the Bamboo server and will be ready to execute jobs from your build plans.

Ensure your Bamboo server is running, then go to Administration > Agents to see your remote agent once it is running.

The following commands need to be run with sudo because Docker needs to run as root. You may need to replace docker with docker.io (depending on your installation) – see http://docker.io.

Pull the remote build agent from the Docker Hub Repository:

```
sudo docker pull atlassian/bamboo-java-agent
```

Once downloaded, run your agent with the following command:

```
sudo docker run -e HOME=/root/ -e BAMBOO_SERVER=http://hostname:port/bamboo -i -t atlassian/bamboo-java-agent:latest
```

Replace `hostname:port` with your Bamboo server's name and port (typically 8085).

Don't use localhost as the server address because for Docker, localhost is in the Docker container, not the host machine.

Go back to Administration > Agents (or refresh that page) and notice that your remote agent has registered itself.

Customization

The two Bamboo agent images are based on our own atlassian/ubuntu-minimal image, which is built using the Docker 'contrib' script and 'debootstrap'.

To customize an image, run it in a container. Name the container for easier access later:
sudo docker run --name="tmp-name" -e HOME=/root/ -i -t
atlassian/bamboo-java-agent:latest /bin/bash

Now change whatever you want inside the container with the usual bash commands. You can enforce some capabilities by changing the file in /root/bamboo-agent-home/bin/bamboo-capabilities.properties.

After that, exit and create a new image from the container like this:

```
sudo docker commit tmp-name atlassian/customized-agent:1.0.0
```

You can publish your new image by pushing it to the Docker Registry.

Troubleshooting

If you have DNS problems (i.e. the Docker container can ping the IP of the server but not the hostname) consider using this command:

```
sudo docker run --dns=your-dns-server-ip1 --dns=your-dns-server-ip2
```

You'll need to replace those values with the actual IP addresses of your DNS server.

If the agent seems to connect and start bootstrapping but has trouble with active mq then check on your Bamboo server that you have set up the broker URL correctly. Go to Administration > General configuration. You should not have 'localhost' specified there.

### Getting started with Docker and Bamboo v6.2

Manage and run your Bamboo remote agents using Docker!

A Bamboo server can use one or more remote build agents (up to 1000 depending on your license). Remote agents execute jobs from your build plan. Because jobs can have different requirements, it is useful to have agents with different capabilities.

Docker is a great way to manage your remote agents, and provides:

- Ease of use – you can automate or script the creation and maintenance of your remote agents.
- Very quick duplication and distribution of changes to remote agents.
- The ability to run multiple remote agents on the same host without conflicting requirements.

Read Configuring the Docker task in Bamboo to see how you can build Docker images, run Docker containers as part of your Bamboo build, and push a Docker image to a Docker registry.

### Docker images

Atlassian has published two images to the Docker Hub at https://hub.docker.com/u/atlassian/.

You can modify these images to suit your own requirements.

**atlassian/bamboo-java-agent**

Suitable for java stack development.

- Bamboo agent .jar (5.6.0)
- OpenJDK 7
- GIT, Mercurial, CVS and SVN
- Maven 2, 3 and Ant

**atlassian/bamboo-base-agent**

Suitable for deep customization.

- Bamboo agent .jar (5.6.0)
- OpenJDK 7

### Bamboo server

Note that the Docker images do not include a Bamboo server. Download and install Bamboo separately before continuing – see Getting started with Bamboo.
Usage

For a new Bamboo installation there will not be any remote agents yet. When you run a remote agent (see below), it will connect to the Bamboo server and will be ready to execute jobs from your build plans.

Ensure your Bamboo server is running, then go to Administration > Agents to see your remote agent once it is running.

The following commands need to be run with sudo because Docker needs to run as root. You may need to replace docker with docker.io (depending on your installation) – see http://docker.io.

Pull the remote build agent from the Docker Hub Repository:

```
sudo docker pull atlassian/bamboo-java-agent
```

Once downloaded, run your agent with the following command:

```
sudo docker run -e HOME=/root/ -e BAMBOO_SERVER=http://hostname:port/bamboo -i -t atlassian/bamboo-java-agent:latest
```

Replace hostname:port with your Bamboo server's name and port (typically 8085).

Don't use localhost as the server address because for Docker, localhost is in the Docker container, not the host machine.

Go back to Administration > Agents (or refresh that page) and notice that your remote agent has registered itself.

Customization

The two Bamboo agent images are based on our own atlassian/ubuntu-minimal image, which is built using the Docker 'contrib' script and 'debootstrap'.

To customize an image, run it in a container. Name the container for easier access later:

```
sudo docker run --name="tmp-name" -e HOME=/root/ -i -t atlassian/bamboo-java-agent:latest /bin/bash
```

Now change whatever you want inside the container with the usual bash commands. You can enforce some capabilities by changing the file in /root/bamboo-agent-home/bin/bamboo-capabilities.properties.

After that, exit and create a new image from the container like this:

```
sudo docker commit tmp-name atlassian/customized-agent:1.0.0
```

You can publish your new image by pushing it to the Docker Registry.

Troubleshooting

If you have DNS problems (i.e. the Docker container can ping the IP of the server but not the hostname) consider using this command:

```
sudo docker run --dns=your-dns-server-ip1 --dns=your-dns-server-ip2
```

You'll need to replace those values with the actual IP addresses of your DNS server.

If the agent seems to connect and start bootstrapping but has trouble with active mq then check on your Bamboo server that you have set up the broker URL correctly. Go to Administration > General configuration. You should not have 'localhost' specified there.
Getting started with Docker and Bamboo v6.3

Manage and run your Bamboo remote agents using Docker.

A Bamboo server can use one or more remote build agents (up to 1000 depending on your license). Remote agents execute jobs from your build plan. Because jobs can have different requirements, it is useful to have agents with different capabilities.

Docker is a great way to manage your remote agents, and provides:

- Ease of use – you can automate or script the creation and maintenance of your remote agents.
- Very quick duplication and distribution of changes to remote agents.
- The ability to run multiple remote agents on the same host without conflicting requirements.

Read Configuring the Docker task in Bamboo to see how you can build Docker images, run Docker containers as part of your Bamboo build, and push a Docker image to a Docker registry.

Docker images

Atlassian has published two images to the Docker Hub at https://hub.docker.com/u/atlassian/.

You can modify these images to suit your own requirements.

atlassian/bamboo-java-agent

Suitable for java stack development.

- Bamboo agent .jar (5.6.0)
- OpenJDK 7
- GIT, Mercurial, CVS and SVN
- Maven 2, 3 and Ant

atlassian/bamboo-base-agent

Suitable for deep customization.

- Bamboo agent .jar (5.6.0)
- OpenJDK 7

Bamboo server

Note that the Docker images do not include a Bamboo server. Download and install Bamboo separately before continuing – see Getting Started with Bamboo.

Usage

For a new Bamboo installation there will not be any remote agents yet. When you run a remote agent (see below), it will connect to the Bamboo server and will be ready to execute jobs from your build plans.

Ensure your Bamboo server is running, then go to Administration > Agents to see your remote agent once it is running.

The following commands need to be run with sudo because Docker needs to run as root. You may need to replace docker with docker.io (depending on your installation) – see http://docker.io.

Pull the remote build agent from the Docker Hub Repository:

```
sudo docker pull atlassian/bamboo-java-agent
```

Once downloaded, run your agent with the following command:

```
sudo docker run -e HOME=/root/ -e BAMBOO_SERVER=http://hostname:port/bamboo -i -t atlassian/bamboo-java-agent:latest
```

Replace hostname:port with your Bamboo server's name and port (typically 8085).

Don't use localhost as the server address because for Docker, localhost is in the Docker container, not the host machine.
Go back to Administration > Agents (or refresh that page) and notice that your remote agent has registered itself.

Customization

The two Bamboo agent images are based on our own atlassian/ubuntu-minimal image, which is built using the Docker 'contrib' script and 'debootstrap'.

To customize an image, run it in a container. Name the container for easier access later:

```
sudo docker run --name="tmp-name" -e HOME=/root/ -i -t atlassian/bamboo-java-agent:latest /bin/bash
```

Now change whatever you want inside the container with the usual bash commands. You can enforce some capabilities by changing the file in `/root/bamboo-agent-home/bin/bamboo-capabilities.properties`.

After that, exit and create a new image from the container like this:

```
sudo docker commit tmp-name atlassian/customized-agent:1.0.0
```

You can publish your new image by pushing it to the Docker Registry.

Troubleshooting

If you have DNS problems (i.e. the Docker container can ping the IP of the server but not the hostname) consider using this command:

```
sudo docker run --dns=your-dns-server-ip1 --dns=your-dns-server-ip2
```

You'll need to replace those values with the actual IP addresses of your DNS server.

If the agent seems to connect and start bootstrapping but has trouble with active mq then check on your Bamboo server that you have set up the broker URL correctly. Go to Administration > General configuration. You should not have 'localhost' specified there.

Getting started with Bamboo v6.0

This page describes how to install, set up, and start using Bamboo.

If you’re upgrading Bamboo, read the Bamboo upgrade guide instead of this page.

For production installs we recommend that you read Bamboo best practice - system requirements.

Atlassian Bamboo is a continuous integration (CI) and deployment server. Bamboo assists software development teams by providing:

- automated building and testing of software source-code status.
- updates on successful and failed builds.
- reporting tools for statistical analysis.

Please see the following pages for information about getting started with Bamboo:

- Bamboo best practice - system requirements
- Understanding the Bamboo CI Server - a conceptual overview of using Bamboo for continuous integration (CI).

1. Install and start Bamboo

See one of:

- Installing Bamboo on Linux
- Installing Bamboo on Mac OS X
- Installing Bamboo on Windows

Once it’s started, you can access Bamboo in your browser at http://localhost:8085/.

2. Set up notifications
Bamboo can send build result notifications using:

- Hipchat - see Integrating Bamboo with Hipchat
- Email - see Configuring Bamboo to send SMTP Email
- Other services - see Notifications

3. Get building with Bamboo

Bamboo has the concept of a 'plan' to look after the configuration for a build. So, to run your first build, you create and run a plan:

- Getting started with Java and Bamboo - a guide to setting up a simple CI workflow for Java code.
- Getting started with .NET and Bamboo - a guide to setting up a simple CI workflow on Windows.

Getting started with Bamboo v5.14

This page describes how to install, set up, and start using Bamboo.

If you're upgrading Bamboo, read the Bamboo upgrade guide instead of this page.

For production installs we recommend that you read Bamboo best practice - system requirements.

Atlassian Bamboo is a continuous integration (CI) and deployment server. Bamboo assists software development teams by providing:

- automated building and testing of software source-code status.
- updates on successful and failed builds.
- reporting tools for statistical analysis.

Please see the following pages for information about getting started with Bamboo:

Supported platforms

This page describes the supported platforms for Bamboo 6.6.

- Java
- Operating systems
- Databases
- Web browsers
- Source repositories
- Application servers
- Agents and custom EC2 images

See also:
- End of support announcements for Bamboo
- Bamboo Best Practice - System Requirements
- Stock images

Definitions:

- **Supported** - you can use Bamboo with this platform.
- **Limited** - you can evaluate Bamboo on this platform, but you can't use it to run a production Bamboo site.
- **Deprecated** - support for this platform will end in an upcoming release.

Java

**Oracle JDK:**

- **Supported** - you can use Bamboo with this platform.

**Java 1.8**

- Once the JDK is installed, you will need to set the `JAVA_HOME` environment variable, pointing to the root directory of the JDK. Some JDK installers set this automatically (check by typing `echo %JAVA_HOME%` in a command prompt, or `echo
$JAVA_HOME in a shell). You need to do this before installing Bamboo, as Bamboo will automatically configure JDK capabilities based on the system environment variables on your machine.

- For Bamboo server, it is not enough to have just the JRE. Please ensure that you have the full JDK.
- You only need to run the agent and server using a supported JDK. Agents can build software with any JDK version.

### Operating systems

**Operating systems:**

- Microsoft Windows
- Linux
- Solaris
- MacOS / OSX

### Databases

**MySQL:**

- MySQL 5.6.3
- MySQL 5.7

**PostgreSQL:**

- PostgreSQL 9.2
- PostgreSQL 9.3
- PostgreSQL 9.4
- PostgreSQL 9.5
- PostgreSQL 9.6
- PostgreSQL 10

**Microsoft SQL Server:**

- SQL Server 2012
- SQL Server 2014
- SQL Server 2016

**Oracle:**

- Oracle 12c

**H2:**

1.4.194 (shipped with Bamboo)

### Web browsers

**Web browsers:**

- Mozilla Firefox
- Chrome
- Safari
- Microsoft Edge
- Microsoft Internet Explorer 11

### Good to know:

- For Linux, you should create a dedicated user to run Bamboo. Bamboo runs as the user it is invoked under and can potentially be abused. See [Installing Bamboo on Linux](#).

### Good to know:

- MySQL is supported when used with the JDBC Connector/J 5.1. Supported only with the InnoDB storage engine.
- PostgreSQL is supported when used with the JDBC driver bundled with Bamboo.
- SQL Server is supported when used with Microsoft’s JDBC driver.
- Bamboo ships with a built-in H2 database, which is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.

### Good to know:

- If not specified otherwise, the latest stable version supported.
Good to know:

- Bamboo 4.2, and later versions, support Subversion 1.7, but use the Subversion 1.6 Workspace Format by default to keep backwards compatibility with older Subversion working copies. You can set the `bamboo.svn.wc.format` system property if your Bamboo plans need to use Subversion 1.7 commands as part of your build scripts. See Setting Bamboo to Support Subversion 1.7 Workspace Format for details.
- Bamboo works with Subversion 1.8, and supports the 1.8 Workspace Format.

**Git**

- 1.8.1.5 and later

**Mercurial:**

- 1.8 and later

**Subversion:**

- 1.5
- 1.6
- 1.7
- 1.8

**Application servers**

Bamboo runs on a bundled Apache Tomcat and it’s the only supported configuration.

**Agents and custom EC2 images**

**Atlassian doesn’t provide support for customized images.** Bamboo provides flexibility to use customized machine images, but it’s impossible for us to support all individual configurations.

Use Bamboo stock images as the base for all image customizations to ensure a minimal level of consistency of your Elastic Bamboo setup.

**Supported platforms v5.14**

This page describes the supported platforms for **Bamboo 6.6**.

- **Java**
- **Operating systems**
- **Application servers**
- **Databases**
- **Web browsers**
- **Source repositories**
- **Agents and custom images**
  - **Java**
  - **Operating systems**

See also:

- **End of support announcements for Bamboo**
- **Bamboo Best Practice - System Requirements**
- **Stock images**

**Java**

You only need to run the agent and server using a supported JDK. Agents can build software with any JDK version.

<td>❌ no</td>
<td></td>
</tr>
</tbody>
</table>

Once the JDK is installed, you will need to set the **JAVA_HOME** environment variable, pointing to the root directory of the JDK. Some JDK installers set this automatically (check by typing `echo %JAVA_HOME%` in a command prompt, or `echo $JAVA_HOME` in a shell). You need to do this before installing Bamboo, as Bamboo will automatically configure JDK capabilities based on the system environment variables on your machine.

Operating systems

Bamboo is a pure Java application and runs on any platform, provided all the JDK requirements are satisfied. However, only the following operating systems are supported:

<table>
<thead>
<tr>
<th>OS</th>
<th>Version</th>
<th>Support</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft Windows</td>
<td>-</td>
<td>✔️ yes</td>
<td></td>
</tr>
<tr>

</tbody>
</table>

Support for these platforms is supported.

### Definitions:

- **Supported** - you can use Bamboo with this platform.
- **Limited** - you can evaluate Bamboo on this platform, but you can't use it to run a production Bamboo site.
- **Deprecated** - support for this platform will end in an upcoming release.

### Java

**Oracle JDK:**

- **Supported** - you can use Bamboo with this platform.

**Open JDK:**

- **Supported** - you can use Bamboo with this platform.

### Good to know:

- Once the JDK is installed, you will need to set the `JAVA_HOME` environment variable, pointing to the root directory of the JDK. Some JDK installers set this automatically (check by typing `echo %JAVA_HOME%` in a command prompt, or `echo $JAVA_HOME` in a shell). You need to do this before installing Bamboo, as Bamboo will automatically configure JDK capabilities based on the system environment variables on your machine.
- For Bamboo server, it is not enough to have just the JRE. Please ensure that you have the full JDK.
- You only need to run the agent and server using a supported JDK. Agents can build software with any JDK version.

### Operating systems

**Operating systems:**

- **Supported** - you can use Bamboo with this platform.

### Good to know:

- For Linux, you should create a dedicated user to run Bamboo. Bamboo runs as the user it is invoked under and can potentially be abused. See Setting Up Bamboo on Linux.
MySQL:
- MySQL 5.6.3
- MySQL 5.7

PostgreSQL:
- PostgreSQL 9.2
- PostgreSQL 9.3
- PostgreSQL 9.4
- PostgreSQL 9.5
- PostgreSQL 9.6

Microsoft SQL Server:
- SQL Server 2012
- SQL Server 2014
- SQL Server 2016

Oracle:
- Oracle 12c

Hyper SQL Database:
- 1.8.0.10

Web browsers:
- Mozilla Firefox
- Chrome
- Safari
- Microsoft Edge
- Microsoft Internet Explorer 11

Source repositories:

CVS

Git:
- 1.8.1.5 and later

Mercurial:
- 1.7 and later

Perforce

Subversion:
- 1.5
- 1.6
- 1.7
- 1.8

Good to know:

MySQL is supported when used with the JDBC Connector/J 5.1.

Supported only with the InnoDB storage engine.

PostgreSQL is supported when used with the JDBC driver bundled with Bamboo.

SQL Server is supported when used with Microsoft's JDBC driver.

Bamboo ships with a built-in HSQL database, which is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.

Good to know:

If not specified otherwise, the latest stable version supported.

Bamboo 4.2, and later versions, support Subversion 1.7, but use the Subversion 1.6 Workspace Format by default to keep backwards compatibility with older Subversion working copies. You can set the bamboo.svn.wc.format system property if your Bamboo plans need to use Subversion 1.7 commands as part of your build scripts.

See Setting Bamboo to Support Subversion 1.7 Workspace Format for details.

Bamboo works with Subversion 1.8, and supports the 1.8 Workspace Format.

Application servers
Bamboo runs on a bundled Apache Tomcat and it's the only supported configuration.

Agents and custom EC2 images

Atlassian doesn’t provide support for customized images. Bamboo provides flexibility to use customized machine images, but it’s impossible for us to support all individual configurations. Use Bamboo stock images as the base for all image customizations to ensure a minimal level of consistency of your Elastic Bamboo setup.

Supported platforms v6.3

This page describes the supported platforms for Bamboo 6.6.

See also:

- For Bamboo server, it is not enough to have just the JRE. Please ensure that you have the full JDK.
- You only need to run the agent and server using a supported JDK. Agents can build software with any JDK version.

Operating systems

Operating systems:
- Microsoft Windows
- Linux
- Solaris
- MacOS / OSX

Good to know:
- For Linux, you should create a dedicated user to run Bamboo. Bamboo runs as the user it is invoked under and can potentially be abused. See Installing Bamboo on Linux.

Databases

MySQL:
- MySQL 5.6.3
- MySQL 5.7

PostgreSQL:
- PostgreSQL 9.2
- PostgreSQL 9.3

Good to know:
- MySQL is supported when used with the JDBC Connector/J 5.1. Supported only with the InnoDB storage engine.
- PostgreSQL is supported when used with the JDBC driver bundled with Bamboo.
- SQL Server is supported when used with Microsoft's JDBC driver.
- Bamboo ships with a built-in H2 database, which is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.
PostgreSQL 9.4
PostgreSQL 9.5
PostgreSQL 9.6
PostgreSQL 10

Microsoft SQL Server:
- SQL Server 2012
- SQL Server 2014
- SQL Server 2016

Oracle:
- Oracle 12c

H2:
- 1.4.194 (shipped with Bamboo)

Web browsers

- Mozilla Firefox
- Chrome
- Safari
- Microsoft Edge
- Microsoft Internet Explorer 11

Source repositories

CVS

Git

- 1.8.1.5 and later

Mercurial:

- 1.8 and later

Perforce

Subversion:

- 1.5
- 1.6
- 1.7
- 1.8

Docker

Docker for Mac:

- 17 or later

Docker for Linux:

- 17 or later

Good to know:

- If not specified otherwise, the latest stable version supported.

Application servers

Bamboo runs on a bundled Apache Tomcat and it’s the only supported configuration.
Agents and custom EC2 images

Atlassian doesn't provide support for customized images. Bamboo provides flexibility to use customized machine images, but it's impossible for us to support all individual configurations.

Use Bamboo stock images as the base for all image customizations to ensure a minimal level of consistency of your Elastic Bamboo setup.

Supported platforms v6.6
This page describes the supported platforms for Bamboo 6.6. See also:

- End of support announcements for Bamboo
- Bamboo Best Practice - System Requirements
- Stock images

Definitions:

- **Supported** - you can use Bamboo with this platform.
- **Limited** - you can evaluate Bamboo on this platform, but you can't use it to run a production Bamboo site.
- **Deprecated** - support for this platform will end in an upcoming release.

Java

**Oracle JDK:**

- ✔ Java 1.8

**Open JDK:**

- ✔ Java 1.8

**Good to know:**

- Once the JDK is installed, you will need to set the `JAVA_HOME` environment variable, pointing to the root directory of the JDK. Some JDK installers set this automatically (check by typing `echo %JAVA_HOME%` in a command prompt, or `echo $JAVA_HOME` in a shell). You need to do this before installing Bamboo, as Bamboo will automatically configure JDK capabilities based on the system environment variables on your machine.
- For Bamboo server, it is not enough to have just the JRE. Please ensure that you have the full JDK.
- You only need to run the agent and server using a supported JDK. Agents can build software with any JDK version.

**Operating systems:**

- ✔ Microsoft Windows
- ✔ Linux
- ✔ Solaris
- ✔ MacOS / OSX

**Databases**

**MySQL:**

- ✔ MySQL 5.6.3
- ✔ MySQL 5.7

**PostgreSQL:**

- ✔ PostgreSQL 9.2
- ✔ PostgreSQL 9.3

**Good to know:**

- MySQL is supported when used with the JDBC Connector/J 5.1.
- PostgreSQL is supported when used with the JDBC driver bundled with Bamboo.
- SQL Server is supported when used with Microsoft's JDBC driver.
- Bamboo ships with a built-in H2 database, which is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.
PostgreSQL 9.4
PostgreSQL 9.5
PostgreSQL 9.6
PostgreSQL 10

- If not specified otherwise, the latest stable version supported.

Application servers

Bamboo runs on a bundled Apache Tomcat and it's the only supported configuration.
Agents and custom EC2 images

Atlassian doesn’t provide support for customized images. Bamboo provides flexibility to use customized machine images, but it’s impossible for us to support all individual configurations.

Use Bamboo stock images as the base for all image customizations to ensure a minimal level of consistency of your Elastic Bamboo setup.

Supported platforms v6.7
This page describes the supported platforms for Bamboo 6.6. See also:

- End of support announcements for Bamboo
- Bamboo Best Practice - System Requirements
- Stock images

Definitions:
- ✔️ Supported - you can use Bamboo with this platform.
- 🚫 Limited - you can evaluate Bamboo on this platform, but you can’t use it to run a production Bamboo site.
- ⚠️ Deprecated - support for this platform will end in an upcoming release.

Java

Oracle JDK:
- ✔️ Java 1.8

Open JDK:
- ✔️ Java 1.8

Good to know:
- Once the JDK is installed, you will need to set the JAVA_HOME environment variable, pointing to the root directory of the JDK. Some JDK installers set this automatically (check by typing ‘echo %JAVA_HOME%’ in a command prompt, or ‘echo $JAVA_HOME’ in a shell). You need to do this before installing Bamboo, as Bamboo will automatically configure JDK capabilities based on the system environment variables on your machine.
- For Bamboo server, it is not enough to have just the JRE. Please ensure that you have the full JDK.
- You only need to run the agent and server using a supported JDK. Agents can build software with any JDK version.

Operating systems

Operating systems:
- ✔️ Microsoft Windows
- ✔️ Linux
- ✔️ Solaris
- ✔️ MacOS / OSX

Databases

MySQL:
- ✔️ MySQL 5.6.3
- ✔️ MySQL 5.7

PostgreSQL:
- 🚫 PostgreSQL 9.2
- 🚫 PostgreSQL 9.3

Good to know:
- MySQL is supported when used with the JDBC Connector/J 5.1.
- Supported with the InnoDB storage engine.
- PostgreSQL is supported when used with the JDBC driver bundled with Bamboo.
- SQL Server is supported when used with Microsoft’s JDBC driver.
- Bamboo ships with a built-in H2 database, which is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.
PostgreSQL 9.4
PostgreSQL 9.5
PostgreSQL 9.6
PostgreSQL 10

Microsoft SQL Server:
- SQL Server 2012
- SQL Server 2014
- SQL Server 2016

Oracle:
- Oracle 12c

H2:
- 1.4.194 (shipped with Bamboo)

- Mozilla Firefox
- Chrome
- Safari
- Microsoft Edge
- Microsoft Internet Explorer 11

Source repositories
- CVS
- Git
- Mercurial:
- Perforce
- Subversion:
- Docker
- Docker for Mac:
- Docker for Linux:

Good to know:
- If not specified otherwise, the latest stable version supported.

Infrastructure

Application servers:
- Bamboo runs on a bundled Apache Tomcat and it's the only supported configuration.
Internet protocols:

- You can run Bamboo in both IPv4 and IPv6 environments.
- Raw IPv6 addresses are not always recognized. See the [IPv6 in Bamboo](#) for limitations and known issues.

### Agents and custom EC2 images:

**Atlassian doesn't provide support for customized images.** Bamboo provides flexibility to use customized machine images, but it's impossible for us to support all individual configurations.

Use Bamboo stock images as the base for all image customizations to ensure a minimal level of consistency of your Elastic Bamboo setup.

### End of support announcements for Bamboo

This page announces the end of support for various platforms and browsers used with Atlassian Bamboo.

**Why is Atlassian ending support for these platforms?**

Atlassian is committed to delivering improvements and bug fixes as fast as possible. We are also committed to providing world class support for all the platforms our customers run our software on. However, as new versions of databases, web browsers etc. are released, the cost of supporting multiple platforms grows exponentially, making it harder to provide the level of support our customers have come to expect from us. Therefore, we no longer support platform versions marked as end-of-life by the vendor, or very old versions that are no longer widely used.

### End of support for JDK 6 and 7

<table>
<thead>
<tr>
<th>Date</th>
<th>Description</th>
</tr>
</thead>
</table>
| 26 October 2015       | We're announcing the end of support for JDK 6 and 7 in Bamboo Server with the upcoming release of Bamboo 5.10. It means that agents, custom images, and Bamboo itself won't run against a JDK less than 8. We highly recommend upgrading to the latest version of JDK 8 as soon as you upgrade to Bamboo 5.10 to avoid any issues with existing agents or custom images. The stock images are upgraded automatically. **Note:** Atlassian doesn't provide support for customized images. Bamboo provides flexibility to use customized machine images, but it's impossible for us to support all individual configurations. **Tips:**  
  - Try to match the layout and scripts of our stock images as closely as possible.  
  - Choose Oracle if you have the choice between Oracle and OpenJDK flavor of JDK. **Related links:**

</tbody>
</table>
### Deprecation of Apache Tomcat 5.5 and 6.0

11 February 2014

In version 5.5, Bamboo will no longer support Apache Tomcat 5.5 and 6.0, and will only support Apache Tomcat 7.0 and above. Bamboo 5.5 is expected to be released later in 2014.

### Deprecation of Internet Explorer 8

15 October 2013

In version 5.3, Bamboo will no longer support Internet Explorer 8, and will only support Internet Explorer 9 and above. Bamboo 5.3 is expected to be released later in 2013.

### Deprecation of Maven Artifact Sharing plugin 8

15 October 2013

In version 5.3, Bamboo will no longer support the Maven artifact sharing plugin. Bamboo 5.3 is expected to be released later in 2013.

### Deprecated Databases for Bamboo

4 October 2011

This section announces the end of Atlassian support for certain database versions for Bamboo. End of support means that Atlassian will not fix bugs related to certain database versions past the support end date.

We will stop supporting the following database versions in Bamboo 3.4, from December 2011:

- MySQL 5.0
- Oracle 10g

The details are below. Please refer to the list of supported platforms for details of platform support for Bamboo. If you have questions or concerns regarding this announcement, please email eol-announcement at atlassian dot com.

#### End of Life Announcement for Database Support

<table>
<thead>
<tr>
<th>Database</th>
<th>Support End Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0</td>
<td>When Bamboo 3.4 releases, after December 2011</td>
</tr>
<tr>
<td>Oracle 10g</td>
<td>When Bamboo 3.4 releases, after December 2011</td>
</tr>
</tbody>
</table>

* Notes for MySQL 5.0 and Oracle 10g:
  - Atlassian intends to end support for MySQL 5.0 and Oracle 10g in Bamboo 3.4. Bamboo 3.3 is the last version that will support MySQL 5.0 and Oracle 10g.
  - 'Support End Date' means that Bamboo 3.3 and previously released versions will continue to work with MySQL 5.0 and Oracle 10g. However, Atlassian will not fix bugs affecting MySQL 5.0 and Oracle 10g past the support end date.
  - Bamboo 3.4 will not be tested with MySQL 5.0 and Oracle 10g.
This section announces the end of Atlassian support for certain Java Platforms for Bamboo.

We will stop supporting the following Java Platforms:

- From Bamboo 3.1, due in the first half of 2011, support for Java Platform 5 (JDK/JRE 1.5) will end.

We are ending support for Java Platform 5, in line with Sun's Java SE Support Road Map (i.e. "End of Service Life" for Java Platform 5 dated October 30, 2009). We are committed to helping our customers understand this decision and assist them in updating to Java Platform 6, our supported Java Platform.

The details are below. Please refer to the Supported platforms for more details regarding platform support for Bamboo. If you have questions or concerns regarding this announcement, please email eol-announcement at atlassian dot com.

**End of Life Announcement for Java Platform Support**

<table>
<thead>
<tr>
<th>Java Platform</th>
<th>Support End Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java Platform 5 (JDK/JRE 1.5)</td>
<td>When Bamboo 3.1 releases, due in the first half of 2011</td>
</tr>
</tbody>
</table>

**Java Platform 5 End of Support Notes:**

- 'Support End Date' means that Bamboo 3.0.x and previous released versions will continue to work with Java Platform 5 (JDK/JRE 1.5), however we will not fix bugs related to Java Platform 5 past the support end date.
- Bamboo 3.1 will only be tested with and support Java Platform 6 (JDK/JRE 1.6).
- If you have concerns with this end of support announcement, please email eol-announcement at atlassian dot com.
This section announces the end of Atlassian support for certain web browser versions for Bamboo. End of support means that Atlassian will not fix bugs related to certain web browser versions past the support end date.

We will **stop supporting the following web browser versions** from Bamboo 3.0, due February 2011:

- Microsoft Internet Explorer 7 (IE7)

The details are below. Please refer to the list of [supported platforms](https://confluence.atlassian.com/display/Atlassian/Supported+Platforms) for details of platform support for Bamboo. If you have questions or concerns regarding this announcement, please email eol-announcement at atlassian dot com.

### End of Life Announcement for Web Browser Support

<table>
<thead>
<tr>
<th>Web Browser</th>
<th>Support End Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft Internet Explorer (version 7 only)</td>
<td>When Bamboo 3.0 releases, due February 2011</td>
</tr>
</tbody>
</table>

**Internet Explorer Notes:**

- Atlassian intends to end support for IE7 in Bamboo 3.0. Bamboo 2.7 is the last version that will support IE7.
- IE8 will still be supported.
- 'Support End Date' means that Bamboo 2.7 and previously released versions will continue to work with IE7. However, we will not fix bugs affecting IE7 past the support end date.
- Bamboo 3.0 will not be tested with IE7.

---

**End of support announcements for Bamboo v5.14**

This page announces the end of support for various platforms and browsers used with Atlassian Bamboo.

**Why is Atlassian ending support for these platforms?**

Atlassian is committed to delivering improvements and bug fixes as fast as possible. We are also committed to providing world class support for all the platforms our customers run our software on. However, as new versions of databases, web browsers etc. are released, the cost of supporting multiple platforms grows exponentially, making it harder to provide the level of support our customers have come to expect from us. Therefore, we no longer support platform versions marked as end-of-life by the vendor, or very old versions that are no longer widely used.

  - Bamboo 3.1 will only be tested with and support Java Platform 6 (JDK/JRE 1.6).
  - If you have concerns with this end of support announcement, please email eol-announcement at atlassian dot com.
This section announces the end of Atlassian support for certain web browser versions for Bamboo. End of support means that Atlassian will not fix bugs related to certain web browser versions past the support end date.

We will stop supporting the following web browser versions from Bamboo 3.0, due February 2011:

- Microsoft Internet Explorer 7 (IE7)

The details are below. Please refer to the list of supported platforms for details of platform support for Bamboo. If you have questions or concerns regarding this announcement, please email eol-announcement at atlassian dot com.

End of Life Announcement for Web Browser Support

<th>Support End Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft Internet Explorer (version 7 only)</td>
<td>When Bamboo 3.0 releases, due February 2011</td>
</tr>
</tbody>
</table>

- Internet Explorer Notes:
  - Atlassian intends to end support for IE7 in Bamboo 3.0. Bamboo 2.7 is the last version that will support IE7.
  - IE8 will still be supported.
  - ‘Support End Date’ means that Bamboo 2.7 and previously released versions will continue to work with IE7. However, we will not fix bugs affecting IE7 past the support end date.
  - Bamboo 3.0 will not be tested with IE7.

End of support announcements for Bamboo v6.2

This page announces the end of support for various platforms and browsers used with Atlassian Bamboo.

Why is Atlassian ending support for these platforms?

Atlassian is committed to delivering improvements and bug fixes as fast as possible. We are also committed to providing world class support for all the platforms our customers run our software on. However, as new versions of databases, web browsers etc. are released, the cost of supporting multiple platforms grows exponentially, making it harder to provide the level of support our customers have come to expect from us. Therefore, we no longer support platform versions marked as end-of-life by the vendor, or very old versions that are no longer widely used.

</table>
| End of support for JDK 6 and 7    | 26 October 2015 | We're announcing the end of support for JDK 6 and 7 in Bamboo Server with the upcoming release of Bamboo 5.10. It means that agents, custom images, and Bamboo itself won't run against a JDK less than 8. We highly recommend upgrading to the latest version of JDK 8 as soon as you upgrade to Bamboo 5.10 to avoid any issues with existing agents or custom images. The stock images are upgraded automatically. **Note:** Atlassian doesn't provide support for customized images. Bamboo provides flexibility to use customized machine images, but it's impossible for us to support all individual configurations. **Tips:**  
  • Try to match the layout and scripts of our stock images as closely as possible.  
  • Choose Oracle if you have the choice between Oracle and OpenJDK flavor of JDK.

This section announces the end of Atlassian support for certain database versions for Bamboo. End of support means that Atlassian will not fix bugs related to certain database versions past the support end date.

We will stop supporting the following database versions in Bamboo 3.4, from December 2011:

- MySQL 5.0
- Oracle 10g

The details are below. Please refer to the list of supported platforms for details of platform support for Bamboo. If you have questions or concerns regarding this announcement, please email eol-announcement at atlassian dot com.

### End of Life Announcement for Database Support

</tr>
</tbody>
</table>

**Notes for MySQL 5.0 and Oracle 10g:**

- Atlassian intends to end support for MySQL 5.0 and Oracle 10g in Bamboo 3.4. Bamboo 3.3 is the last version that will support MySQL 5.0 and Oracle 10g.
- ‘Support End Date’ means that Bamboo 3.3 and previously released versions will continue to work with MySQL 5.0 and Oracle 10g. However, Atlassian will not fix bugs affecting MySQL 5.0 and Oracle 10g past the support end date.
- Bamboo 3.4 will not be tested with MySQL 5.0 and Oracle 10g.
This section announces the end of Atlassian support for certain Java Platforms for Bamboo.

We will **stop supporting the following Java Platforms:**

- From Bamboo 3.1, due in the first half of 2011, support for Java Platform 5 (JDK/JRE 1.5) will end.

We are ending support for Java Platform 5, in line with Sun's Java SE Support Road Map (i.e. "End of Service Life" for Java Platform 5 dated October 30, 2009). We are committed to helping our customers understand this decision and assist them in updating to Java Platform 6, our supported Java Platform.

The details are below. Please refer to the Supported platforms for more details regarding platform support for Bamboo. If you have questions or concerns regarding this announcement, please email eol-announcement at atlassian dot com.

### End of Life Announcement for Java Platform Support

<table>

### Deprecated Databases for Bamboo

4 October 2011

This section announces the end of Atlassian support for certain database versions for Bamboo. End of support means that Atlassian will not fix bugs related to certain database versions past the support end date.

We will stop supporting the following database versions in Bamboo 3.4, from December 2011:

- MySQL 5.0
- Oracle 10g

The details are below. Please refer to the list of supported platforms for details of platform support for Bamboo. If you have questions or concerns regarding this announcement, please email eol-announcement at atlassian dot com.

#### End of Life Announcement for Database Support

</tbody>
</table>

**Java Platform 5 End of Support Notes:**

- ‘Support End Date’ means that Bamboo 3.0.x and previous released versions will continue to work with Java Platform 5 (JDK/JRE 1.5), however we will not fix bugs related to Java Platform 5 past the support end date.
- Bamboo 3.1 will only be tested with and support Java Platform 6 (JDK/JRE 1.6).
- If you have concerns with this end of support announcement, please email eol-announcement at atlassian dot com.
Installing Bamboo on Linux

In this guide we'll run you through installing Bamboo with an external database on Linux.

Other ways to install Bamboo:

- **Evaluation** - get your free trial up and running in no time.
- **Windows** – install Bamboo on a Windows server.

Before you begin

Before you install Bamboo, there are a few questions you need to answer.

Are you using a supported operating system?

**Tell me more...**

Check the [Supported platforms](#) page for the version of Bamboo you are installing. This will give you info on supported operating systems, databases and browsers.

Good to know:

- We only support Bamboo on x86 and 64 bit x86 derived hardware platforms.
- You will need permissions for both the Bamboo installation and home directories.

On this page:

- Before you begin
- Install Bamboo
  1. Download Bamboo
  2. Create the installation directory
  3. Create the home directory
  4. Start Bamboo
- Start using Bamboo

### Deprecated Web Browsers for Bamboo

<table>
<thead>
<tr>
<th>Web Browser</th>
<th>Support End Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft Internet Explorer (version 7 only)</td>
<td>When Bamboo 3.0 releases, due February 2011</td>
</tr>
</tbody>
</table>

End of Life Announcement for Web Browser Support

**Internet Explorer Notes:**

- Atlassian intends to end support for IE7 in Bamboo 3.0. Bamboo 2.7 is the last version that will support IE7.
- IE8 will still be supported.
- 'Support End Date' means that Bamboo 2.7 and previously released versions will continue to work with IE7. However, we will not fix bugs affecting IE7 past the support end date.
- Bamboo 3.0 will not be tested with IE7.

### Installing Bamboo on Linux

In this guide we'll run you through installing Bamboo with an external database on Linux.

Other ways to install Bamboo:

- **Evaluation** - get your free trial up and running in no time.
- **Windows** – install Bamboo on a Windows server.

Before you begin

Before you install Bamboo, there are a few questions you need to answer.

Are you using a supported operating system?

**Tell me more...**

Check the [Supported platforms](#) page for the version of Bamboo you are installing. This will give you info on supported operating systems, databases and browsers.

Good to know:

- We only support Bamboo on x86 and 64 bit x86 derived hardware platforms.
- You will need permissions for both the Bamboo installation and home directories.
Is your JAVA_HOME variable set correctly?

Before you install Bamboo, check that you're running a supported Java version and that the JAVA_HOME environment variable is set correctly.

Bamboo can only run with the JDK (not JRE).

To check your Java version:

```
$ java -version
```

To check your JAVA_HOME variable is set correctly:

```
$ echo $JAVA_HOME
```

If you see a path to your Java installation directory, the JAVA_HOME environment variable has been set correctly. If a path is not returned you'll need to set your JAVA_HOME environment variable manually before installing Bamboo.

Create a dedicated user to run Bamboo.

Bamboo runs as the user it is invoked under and can potentially be abused.

An example of how to create a dedicated user to run Bamboo in Linux:

```
$ sudo /usr/sbin/useradd --create-home --home-dir /usr/local/bamboo --shell /bin/bash bamboo
```

Install Bamboo

1. Download Bamboo

Download the tar.gz file for your operating system - https://www.atlassian.com/software/bamboo/download

2. Create the installation directory

   a) Extract the downloaded file to an install location.

   b) The path to the extracted directory is referred to as the <Bamboo installation directory> in these instructions.

3. Create the home directory

   Specify your Bamboo home directory, where your Bamboo data is stored, before you run Bamboo for the first time.

   a) Create your Bamboo home directory (without spaces in the name).

      Note: You should not create your Bamboo home directory inside the <Bamboo installation directory> — they should be entirely separate locations. If you do put the home directory in the <Bamboo installation directory> it will be overwritten, and lost, when Bamboo is upgraded.

   b) Open <Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties

   c) Uncomment the bamboo.home line.

   d) Provide the absolute path absolute path to your home directory.

      Example:

      bamboo.home= /home/nathan/bamboo/bamboo-home

4. Start Bamboo

   a) In the command line, change the directory to <Bamboo installation directory> and run the following command:
bin/start-bamboo.sh

b) In your Web browser, enter the following address: http://localhost:8085/

Start using Bamboo

That’s it! Your Bamboo site is accessible from a URL like this: http://<computer_name_or_IP_address>:<port>

Here’s a few things that will help you get your team up and running:

- Set up Bamboo
- Running Bamboo as a service

Running into problems installing Bamboo?

If something is not working correctly after you have completed the steps above to install Bamboo, please check for known Bamboo issues and try troubleshooting your upgrade as described below:

- Check for known issues. Sometimes we find out about a problem with the latest version of Bamboo after we have released the software. In such cases we publish information about the known issues in the Bamboo Knowledge Base. Please check the known issues in the Bamboo Knowledge Base and follow the instructions to apply any necessary patches if necessary.

- Did you encounter a problem during the Bamboo installation? Please refer to the guide to troubleshooting upgrades in the Bamboo Knowledge Base.

- If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.

Installing Bamboo on Linux v5.14

This page contains instructions to help you install Bamboo on Linux.

Note that Bamboo ships with a built-in HSQL database, which is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.

1. Check supported platforms

Better check the Supported platforms page first; it lists the application servers, databases, operating systems, web browsers and JDKs that we have tested Bamboo with and recommend.

Note that Atlassian currently only supports Bamboo on x86 and 64 bit x86 derived hardware platforms.
On this page:
1. Check supported platforms
2. Check your version of Java
3. Check permissions
4. Download Bamboo
5. Specify your Bamboo home location
6. Start Bamboo!
7. Configure Bamboo
8. Running Bamboo as a service
• Known issues and troubleshooting

Related pages:
• Running the Bamboo Setup Wizard

2. Check your version of Java

In a terminal, run this command:

```
java -version
```

The version of Java should be 1.8.x. Note that Bamboo requires the Java JDK to work, not the Java JRE.

⚠️ If you don't see a supported version, then get Java...
**Install Java**

Download and install the Java Platform JDK (not the JRE) from Oracle’s website.

Now try running `java -version` again to check the installation. The version of Java should be 1.8.x.

**Check that the system can find Java**

In a terminal, run this:

```bash
echo $JAVA_HOME
```

You should see a path like `/System/Library/Frameworks/JavaVM.framework/Versions/CurrentJDK/Home/`.

**Set your JAVA_HOME if you don’t see a path**

### Linux

Do either of the following:

- If `JAVA_HOME` is not set, log in with ‘root’ level permissions and run:

  ```bash
echo JAVA_HOME="path/to/JAVA_HOME" >> /etc/environment
  ```

  where `path/to/JAVA_HOME` may be like: `/System/Library/Frameworks/JavaVM.framework/Versions/CurrentJDK/Home/`

- If `JAVA_HOME` needs to be changed, open the `/etc/environment` file in a text editor and modify the value for `JAVA_HOME` to:

  ```bash
  JAVA_HOME="path/to/JAVA_HOME"
  ```

  It should look like:

  ```bash
  JAVA_HOME=/System/Library/Frameworks/JavaVM.framework/Versions/CurrentJDK/Home/
  ```

**3. Check permissions**

Check your system permissions. You will need to have permissions for both the Bamboo installation and home directories.

**4. Download Bamboo**

Download Bamboo from the Atlassian download site.

Extract the downloaded file to an install location. The path to the extracted directory is referred to as the `<Bamboo installation directory>` in these instructions.

**5. Specify your Bamboo home location**

The Bamboo home directory is where your Bamboo data is stored.

You need to specify your Bamboo home directory before you run Bamboo for the first time.

Create your Bamboo home directory (without spaces in the name), and then edit `<Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties file – uncomment the bamboo.home line and add the absolute path to your home directory. Here’s an example of what that could look like when you’re done:
6. Start Bamboo!

In a terminal, change directory to `<Bamboo installation directory>` and run this command:

```
bin/start-bamboo.sh
```

Access your running Bamboo instance by going to your web browser and entering the address: `http://localhost:8085/`.

7. Configure Bamboo

Configure Bamboo using the Setup Wizard that is displayed. Read Running the Setup Wizard for further instructions.

8. Running Bamboo as a service

If you want to run Bamboo as a service, then please consult Running Bamboo as a service.

Known issues and troubleshooting

If something is not working correctly after you have completed the steps above to install Bamboo, please check for known Bamboo issues and try troubleshooting your upgrade as described below:

- **Check for known issues.** Sometimes we find out about a problem with the latest version of Bamboo after we have released the software. In such cases we publish information about the known issues in the Bamboo Knowledge Base. Please check the known issues in the Bamboo Knowledge Base and follow the instructions to apply any necessary patches if necessary.

- **Did you encounter a problem during the Bamboo installation?** Please refer to the guide to troubleshooting upgrades in the Bamboo Knowledge Base.

- **If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.**

Installing Bamboo on Linux v5.15

In this guide we’ll run you through installing Bamboo with an external database on Linux.
| Are you using a supported operating system? | ![Tell me more...](https://www.atlassian.com/software/bamboo/download)  
Check the Supported platforms page for the version of Bamboo you are installing. This will give you info on supported operating systems, databases and browsers.  
**Good to know:**  
- We only support Bamboo on x86 and 64 bit x86 derived hardware platforms.  
- You will need permissions for both the Bamboo installation and home directories. |
|---|---|
| Is your JAVA_HOME variable set correctly? | ![Tell me more...](https://www.atlassian.com/software/bamboo/download)  
Before you install Bamboo, check that you're running a supported Java version and that the JAVAX_HOME environment variable is set correctly.  
**Bamboo can only run with the JDK (not JRE).**  
To check your Java version:  
```
$ java -version
```
To check your JAVA_HOME variable is set correctly:  
```
$ echo $JAVA_HOME
```
If you see a path to your Java installation directory, the JAVA_HOME environment variable has been set correctly. If a path is not returned you'll need to set your JAVA_HOME environment variable manually before installing Bamboo. |
| Create a dedicated user to run Bamboo. | ![Tell me more...](https://www.atlassian.com/software/bamboo/download)  
Bamboo runs as the user it is invoked under and can potentially be abused.  
An example of how to create a dedicated user to run Bamboo in Linux:  
```
$ sudo /usr/sbin/useradd --create-home --home-dir /usr/local/bamboo --shell /bin/bash bamboo
```

## Install Bamboo

1. **Download Bamboo**

   Download the tar.gz file for your operating system - [https://www.atlassian.com/software/bamboo/download](https://www.atlassian.com/software/bamboo/download)

2. **Create the installation directory**

   a) Extract the downloaded file to an install location.  
   b) The path to the extracted directory is referred to as the `<Bamboo installation directory>` in these instructions.

3. **Create the home directory**

   Specify your Bamboo home directory, where your Bamboo data is stored, before you run Bamboo for the first time.  
   a) Create your Bamboo home directory (without spaces in the name).  
   **Note:** You should not create your Bamboo home directory inside the `<Bamboo installation directory>` — they should be entirely separate locations. If you do put the home directory in the overwritten, and lost, when Bamboo is upgraded.  
   b) Open `<Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`  
   c) Uncomment the `bamboo.home` line.  
   d) Provide the absolute path absolute path to your home directory.  
   **Example:**  
   `bamboo.home= /home/nathan/bamboo/bamboo-home`
4. Start Bamboo

a) In the command line, change the directory to `<Bamboo installation directory>` and run the following command:
   
   `bin/start-bamboo.sh`

b) In your Web browser, enter the following address: `http://localhost:8085/`

Start using Bamboo

That's it! Your Bamboo site is accessible from a URL like this: `http://<computer_name_or_IP_address>:<port>`

Here's a few things that will help you get your team up and running:

- Set up Bamboo
- Running Bamboo as a service

Running into problems installing Bamboo?

If something is not working correctly after you have completed the steps above to install Bamboo, please check for known Bamboo issues and try troubleshooting your upgrade as described below:

- **Check for known issues.** Sometimes we find out about a problem with the latest version of Bamboo after we have released the software. In such cases we publish information about the known issues in the Bamboo Knowledge Base. Please check the known issues in the Bamboo Knowledge Base and follow the instructions to apply any necessary patches if necessary.

- **Did you encounter a problem during the Bamboo installation?** Please refer to the guide to troubleshooting upgrades in the Bamboo Knowledge Base.

- If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.

Installing Bamboo on Linux v6.1

In this guide we'll run you through installing Bamboo with an external database on Linux.

Other ways to install Bamboo:

- **Evaluation** - get your free trial up and running in no time.
- **Windows** – install Bamboo on a Windows server.

Before you begin

Before you install Bamboo, there are a few questions you need to answer.

Are you using a supported operating system?

Tell me more...
Check the Supported platforms page for the version of Bamboo you are installing. This will give you info on supported operating systems, databases and browsers.

**Good to know:**
- We only support Bamboo on x86 and 64 bit x86 derived hardware platforms.
- You will need permissions for both the Bamboo installation and home directories.

Is your JAVA_HOME variable set correctly?

Tell me more...

Before you install Bamboo, check that you're running a supported Java version and that the JAVA_HOME environment variable is set correctly.

**Bamboo can only run with the JDK (not JRE).**

To check your Java version:

```
$ java -version
```

To check your JAVA_HOME variable is set correctly:

```
$ echo $JAVA_HOME
```

If you see a path to your Java installation directory, the JAVA_HOME environment variable has been set correctly. If a path is not returned you'll need to set your JAVA_HOME environment variable manually before installing Bamboo.

Create a dedicated user to run Bamboo.

Bamboo runs as the user it is invoked under and can potentially be abused.

Tell me more...

An example of how to create a dedicated user to run Bamboo in Linux:

```
$ sudo /usr/sbin/useradd --create-home --home-dir /usr/local/bamboo --shell /bin/bash bamboo
```

Install Bamboo

1. **Download Bamboo**
   
   Download the tar.gz file for your operating system - [https://www.atlassian.com/software/bamboo/download](https://www.atlassian.com/software/bamboo/download)

2. **Create the installation directory**
   
   a) Extract the downloaded file to an install location.
   
   b) The path to the extracted directory is referred to as the `<Bamboo installation directory>` in these instructions.

3. **Create the home directory**

   Specify your Bamboo home directory, where your Bamboo data is stored, before you run Bamboo for the first time.

   a) Create your Bamboo home directory (without spaces in the name).

   **Note:** You should not create your Bamboo home directory inside the `<Bamboo installation directory>` — they should be entirely separate locations. If you do put the home directory in the `<Bamboo installation directory>` it will be overwritten, and lost, when Bamboo is upgraded.

   b) Open `<Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`

   c) Uncomment the `bamboo.home` line.

   d) Provide the absolute path absolute path to your home directory.

   **Example:**
   ```
   bamboo.home= /home/nathan/bamboo/bamboo-home
   ```
4. Start Bamboo

   a) In the command line, change the directory to `<Bamboo installation directory>` and run the following command:

   ```
   bin/start-bamboo.sh
   ```

   b) In your Web browser, enter the following address:

   ```
   http://localhost:8085/
   ```

Start using Bamboo

That's it! Your Bamboo site is accessible from a URL like this: `http://<computer_name_or_IP_address>:<port>`

Here's a few things that will help you get your team up and running:

- Set up Bamboo
- Running Bamboo as a service

Running into problems installing Bamboo?

If something is not working correctly after you have completed the steps above to install Bamboo, please check for known Bamboo issues and try troubleshooting your upgrade as described below:

- Check for known issues. Sometimes we find out about a problem with the latest version of Bamboo after we have released the software. Before you begin

Before you install Bamboo, there are a few questions you need to answer.

Are you using a supported operating system?

- Tell me more...

    Check the Supported platforms page for the version of Bamboo you are installing. This will give you info on supported operating systems, databases and browsers.
Good to know:

- We only support Bamboo on x86 and 64 bit x86 derived hardware platforms.
- You will need permissions for both the Bamboo installation and home directories.

Is your JAVA_HOME variable set correctly?

Tell me more...

Before you install Bamboo, check that you're running a supported Java version and that the JAVA_HOME environment variable is set correctly.

Bamboo can only run with the JDK (not JRE).

To check your Java version:

```
java -version
```

To check your JAVA_HOME variable is set correctly:

```
echo $JAVA_HOME
```

If you see a path to your Java installation directory, the JAVA_HOME environment variable has been set correctly. If a path is not returned you'll need to set your JAVA_HOME environment variable manually before installing Bamboo.

1. Download Bamboo

1. Download the Bamboo tar.gz archive.
2. Extract the downloaded file to a selected location.
   The path to the extracted directory is referred to as the <Bamboo installation directory> in these instructions.

2. Specify your Bamboo home location

Specify your Bamboo home directory, where your Bamboo data is stored, before you run Bamboo for the first time.

a) Create your Bamboo home directory (without spaces in the name).

   Note: You should not create your Bamboo home directory inside the <Bamboo installation directory> — they should be entirely separate locations. If you do put the home directory in the <Bamboo installation directory> it will be overwritten, and lost, when Bamboo is upgraded.

b) Open <Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties.
c) Uncomment the bamboo.home line.
d) Provide the absolute path to your home directory.

Example:

```
bamboo.home= /home/nathan/bamboo/bamboo-home
```

3. Start Bamboo

a) In the command line, change the directory to <Bamboo installation directory> and run the following command:

```
bin/start-bamboo.sh
```

b) In your Web browser, enter the following address: http://localhost:8085/

4. Configure Bamboo

Follow the Setup Wizard to configure Bamboo. See Running the Setup Wizard.

Start using Bamboo

That's it! Your Bamboo site is accessible from a URL like this: http://<computer_name_or_IP_address>:<port>

Here's a few things that will help you get your team up and running:

- Set up Bamboo
- Running Bamboo as a service

**Installing Bamboo on Mac OS X v5.14**

This page contains instructions to help you install Bamboo on Mac.

Note that Bamboo ships with a built-in HSQL database, which is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.

1. **Check supported platforms**

   Better check the Supported platforms page first; it lists the application servers, databases, operating systems, web browsers and JDKs that we have tested Bamboo with and recommend.

   Note that Atlassian currently only supports Bamboo on x86 and 64-bit x86 derived hardware platforms.

---

### On this page:

1. Check supported platforms
2. Install Java
3. Check permissions
4. Download Bamboo
5. Start Bamboo!
6. Configure Bamboo
7. Running Bamboo as a service

### Related pages:

- Running the Bamboo Setup Wizard

---

2. **Install Java**

   **Using Mac OS X 10.9 Mavericks?**
To check if you have Java installed, and the version, run this command in a terminal:

```
java -version
```

The version of Java should be **1.8.x**.

If Java is not on your system, Mac OS X will prompt you to install it. You can test that it installed correctly by running the command above a second time.

### 3. Check permissions

Check your system permissions. You will need to have permissions for both the Bamboo installation and home directories.

### 4. Download Bamboo

1. Download the Bamboo tar.gz archive from the Atlassian download site.
2. Extract the downloaded file to an install location. The path to the extracted directory is referred to as the `<Bamboo installation directory>` in these instructions.
3. Create your Bamboo home directory (without spaces in the name), and then edit the `<Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties` file – uncomment the `bamboo.home` line and add the absolute path to your home directory. Here’s an example of what that could look like when you’re done:

```
# You can specify your bamboo.home property here or in your system environment variables.

bamboo.home=/home/nathan/bamboo/bamboo-home
```

**Important**

You should not locate your Bamboo home directory inside the `<Bamboo installation directory>` — they should be entirely separate locations. If you do put the home directory in the `<Bamboo installation directory>` it will be overwritten, and lost, when Bamboo gets upgraded.

You must use forward slashes in your directory path. Backslashes are not recognized by Bamboo.

### 5. Start Bamboo!

In Terminal, change directory to `<Bamboo installation directory>` and run this command:

```
bin/start-bamboo.sh
```

Access your running Bamboo instance by going to your web browser and entering the address: `http://localhost:8085`.

### 6. Configure Bamboo

Configure Bamboo using the Setup Wizard that is displayed. Read Running the Setup Wizard for further instructions.

### 7. Running Bamboo as a service

If you want to run Bamboo as a service, then please consult Running Bamboo as a service.

If something is not working correctly after you have completed the steps above to install Bamboo, please check for known Bamboo issues and try troubleshooting your upgrade as described below:
• **Check for known issues.** Sometimes we find out about a problem with the latest version of Bamboo after we have released the software. In such cases we publish information about the known issues in the Bamboo Knowledge Base. Please check the known issues in the Bamboo Knowledge Base and follow the instructions to apply any necessary patches if necessary.

• **Did you encounter a problem during the Bamboo installation?** Please refer to the guide to troubleshooting upgrades in the Bamboo Knowledge Base.

• If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.

### Installing Bamboo on Mac OS X v5.15

Installing Bamboo on Windows

In this guide we'll run you through installing Bamboo with an external database on Windows.

Before you begin:

Before you install Bamboo, there are a few questions you need to answer.

Are you using a supported operating system?

◇ Tell me more...

Check the Supported platforms page for the version of Bamboo you are installing. This will give you info on supported operating systems.
systems, databases and browsers.

**Good to know:**
- We only support Bamboo on x86 and 64 bit x86 derived hardware platforms.
- You will need permissions for both the Bamboo installation and home directories.

Is your JAVA_HOME variable set correctly?

Tell me more...

Before you install Bamboo, check that you’re running a supported Java version and that the JAVA_HOME environment variable is set correctly.

**Bamboo can only run with the JDK (not JRE).**

To check your Java version:

```
java -version
```

To check your JAVA_HOME variable is set correctly:

```
echo %JAVA_HOME%
```

If you see a path to your Java installation directory, the JAVA_HOME environment variable has been set correctly. If a path is not returned you’ll need to set your JAVA_HOME environment variable manually before installing Bamboo.

---

**1. Download Bamboo**

Download Bamboo from the Atlassian download site. You can choose either the Windows Installer version (.exe) or a ZIP Archive (.zip).

It is highly recommended to avoid placing the Bamboo home directory in any Windows security controlled directory, for example, C:\Program Files.

**Installing using the Windows Installer**

1. Launch the Bamboo Windows installer to begin the installation wizard.
2. The installer requires you to specify two directories:
   - **Destination directory**— This is the directory where Bamboo's application files will be installed. The default is:
     ```
     C:\Program Files\Bamboo
     ```
   - **Bamboo home directory**— This is the directory where Bamboo will store its configuration data. If the directory you specify doesn't exist, Bamboo will create the directory when it launches. The default is:
     ```
     C:\Users\<current-user>\Bamboo-home
     ```

   Ensure that the Bamboo home directory is not located inside the Bamboo installation directory.

**Installing using the Zip archive**

1. Extract the files from the zip Archive to a <Bamboo installation directory> of your choice. By default, the root directory in your zip file is named “Bamboo”.

   **Warning: Some unzip programs cause errors**
   Some archive-extract programs cause errors when unzipping the Bamboo archive file. We highly recommend that you use the free 7Zip archive-extract program (if in doubt, download the '32-bit .exe' version).
ii. Set up your **Bamboo home directory** — this is the directory where Bamboo will store its root configuration data. To do this, edit the file named `bamboo-init.properties` in the `<Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/` directory. In this file, insert the property “bamboo.home”, with an absolute path to your Bamboo home directory. Your file should look something like this:

```
bamboo.home=C:/test/bamboo-home
```

Alternatively, you can specify an environment variable ‘BAMBOO_HOME’ which specifies the absolute path to your Bamboo home directory. Bamboo will check if an environment variable is defined.

iii. If you are going to use Bamboo remote agents, set the following in the `bamboo-init.properties` file in the `<Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes` directory:

```
bamboo.jms.broker.uri=tcp://localhost:54663
```

- Replace ‘localhost’ with the real host name or IP address of your Bamboo server.
- If port number 54663 is already in use, specify a different port number

2. Start Bamboo

   a) In the command line, change the directory to `<Bamboo installation directory>` and run the following command:

   ```
   bin\start-bamboo.bat
   ```

   b) In your Web browser, enter the following address: http://localhost:8085/

3. Configure Bamboo

   Follow the Setup Wizard to configure Bamboo. See [Running the Setup Wizard](#).

Start using Bamboo

That's it! Your Bamboo site is accessible from a URL like this: http://<computer_name_or_IP_address>:<port>

Here's a few things that will help you get your team up and running:

### Installing Bamboo on Windows v5.14

This page describes how to install Atlassian Bamboo on Windows.

Note that Bamboo ships with a built-in HSQL database, which is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.

#### 1. Check supported platforms

Better check the [Supported platforms](#) page first; it lists the application servers, databases, operating systems, web browsers and JDKs that we have tested Bamboo with and recommend.

Note that Atlassian currently only supports Bamboo on x86 and 64-bit x86 derived hardware platforms.

#### 2. Check your version of Java

In a command prompt, run this command:

```
java -version
```

The version of Java should be 1.8.x. Note that Bamboo requires the Java JDK to work, not the Java JRE.

* If you don't see a supported version, then get Java...

##### Install Java

Download and install the Java Platform JDK (not the JRE) from Oracle's website.

Now try running `java -version` again in a new command prompt, to check the installation. The version of Java should be 1.8.x.

#### 3. Check that Windows can find Java

Bamboo uses the `JAVA_HOME` environment variable to find Java. To check that, in a command prompt, run:

```
echo %JAVA_HOME%
```

You should see a path to the root directory of the Java installation. When running Bamboo on Windows, unlike Linux or Unix, `JAVA_HOME`
paths with spaces are just fine.

If you don't see a path...

```
If you don't see a path, or if you just see %JAVA_HOME%, then set JAVA_HOME as follows:
```

**For Windows 7:**

1. Go to Start, search for “sys env” and choose Edit the system environment variables.
2. Click Environment Variables, and then New under ‘System variables’.
3. Enter “JAVA_HOME” as the Variable name, and the absolute path to where you installed Java as the Variable value. Don’t use a trailing backslash, and don’t wrap the value in quotes.

Now, in a new command prompt, try running `$JAVA_HOME\bin\java -version`. You should see the same version of Java as you saw in 2. above.

4. **Check permissions**

Check your system permissions. You will need to have permissions for both the Bamboo installation and home directories.

5. **Download Bamboo**

Download Bamboo from the Atlassian download site. You can choose either the Windows Installer version (.exe) or a ZIP Archive (.zip).

**Installing using the Windows Installer**

1. Launch the Bamboo Windows installer to begin the installation wizard.
2. The installer requires you to specify two directories:
   - **Destination directory**— This is the directory where Bamboo’s application files will be installed. The default is:
   ```
   C:\Program Files\Bamboo
   ```
   - **Bamboo home directory**— This is the directory where Bamboo will store its configuration data. If the directory you specify doesn’t exist, Bamboo will create the directory when it launches. The default is:
   ```
   C:\Users\<current-user>\Bamboo-home
   ```

Ensure that the Bamboo home directory is not located inside the <Bamboo installation directory>.

**Installing using the Zip archive**

1. Extract the files from the zip Archive to a <Bamboo installation directory> of your choice. By default, the root directory in your zip file is named “Bamboo”.

   **Warning: Some unzips programs cause errors**

   Some archive-extract programs cause errors when unzipping the Bamboo archive file. We highly recommend that you use the free 7Zip archive-extract program (if in doubt, download the ‘32-bit .exe’ version).

2. Set up your **Bamboo home directory** — this is the directory where Bamboo will store its root configuration data. To do this, edit the file named bamboo-init.properties in the <Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/ directory. In this file, insert the property “bamboo.home”, with an absolute path to your Bamboo home directory. Your file should look something like this:

   ```
   bamboo.home=C:/test/bamboo-home
   ```

   Alternatively, you can specify an environment variable 'BAMBOO_HOME' which specifies the absolute path to your Bamboo home directory. Bamboo will check if an environment variable is defined.
3. If you are going to use Bamboo remote agents, set the following in the bamboo-init.properties file in the <Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes directory:
bamboo.jms.broker.uri=tcp://localhost:54663

- Replace 'localhost' with the real host name or IP address of your Bamboo server.
- If port number 54663 is already in use, specify a different port number.

6. Start Bamboo!

In a terminal, change directory to `<Bamboo installation directory>` and run this command:

```
bin\start-bamboo.bat
```

Access your running Bamboo instance by going to your web browser and entering the address: http://localhost:8085/.

7. Configure Bamboo

Configure Bamboo using the Setup Wizard that is displayed. Read Running the Setup Wizard for further instructions.

8. Running Bamboo as a service

If you want to run Bamboo as a service, then please consult Running Bamboo as a service.

If something is not working correctly after you have completed the steps above to install Bamboo, please check for known Bamboo issues and try troubleshooting your upgrade as described below:

- **Check for known issues.** Sometimes we find out about a problem with the latest version of Bamboo after we have released the software. In such cases we publish information about the known issues in the Bamboo Knowledge Base. Please check the known issues in the Bamboo Knowledge Base and follow the instructions to apply any necessary patches if necessary.

- **Did you encounter a problem during the Bamboo installation?** Please refer to the guide to troubleshooting upgrades in the Bamboo Knowledge Base.

- If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.

. Installing Bamboo on Windows v5.15

In this guide we’ll run you through installing Bamboo with an external database on Windows.

<table>
<thead>
<tr>
<th>On this page</th>
<th>Before you begin:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1. Download Bamboo</td>
</tr>
<tr>
<td></td>
<td>2. Start Bamboo</td>
</tr>
<tr>
<td></td>
<td>3. Configure Bamboo</td>
</tr>
<tr>
<td></td>
<td>Start using Bamboo</td>
</tr>
<tr>
<td></td>
<td>Troubleshooting</td>
</tr>
</tbody>
</table>

Before you begin:

Before you install Bamboo, there are a few questions you need to answer.

<table>
<thead>
<tr>
<th>Are you using a supported operating system?</th>
<th>Tell me more...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check the Supported platforms page for the version of Bamboo you are installing. This will give you info on supported operating systems, databases and browsers.</td>
<td></td>
</tr>
</tbody>
</table>

**Good to know:**

- We only support Bamboo on x86 and 64 bit x86 derived hardware platforms.
- You will need permissions for both the Bamboo installation and home directories.
Is your `JAVA_HOME` variable set correctly?

**Tell me more...**

Before you install Bamboo, check that you’re running a supported Java version and that the `JAVA_HOME` environment variable is set correctly.

**Bamboo can only run with the JDK (not JRE).**

To check your Java version:

```
java -version
```

To check your `JAVA_HOME` variable is set correctly:

```
echo %JAVA_HOME%
```

If you see a path to your Java installation directory, the `JAVA_HOME` environment variable has been set correctly. If a path is not returned you’ll need to set your `JAVA_HOME` environment variable manually before installing Bamboo.

---

### 1. Download Bamboo

Download Bamboo from the Atlassian [download site](https://www.atlassian.com). You can choose either the Windows Installer version (`.exe`) or a ZIP Archive (`.zip`).

It is highly recommended to avoid placing the **Bamboo home directory** in any Windows security controlled directory, for example, `C:\Program Files`.

#### Installing using the Windows Installer

1. Launch the Bamboo Windows installer to begin the installation wizard.
2. The installer requires you to specify two directories:
   - **Destination directory** — This is the directory where Bamboo’s application files will be installed. The default is:
     ```
     C:\Program Files\Bamboo
     ```
   - **Bamboo home directory** — This is the directory where Bamboo will store its configuration data. If the directory you specify doesn't exist, Bamboo will create the directory when it launches. The default is:
     ```
     C:\Users\<current-user>\Bamboo-home
     ```

   Ensure that the Bamboo home directory is not located inside the `<Bamboo installation directory>`.

#### Installing using the Zip archive

1. Extract the files from the zip Archive to a `<Bamboo installation directory>` of your choice. By default, the root directory in your zip file is named "Bamboo".

   **Warning: Some unzip programs cause errors**

   Some archive-extract programs cause errors when unzipping the Bamboo archive file. We highly recommend that you use the free 7Zip archive-extract program (if in doubt, download the ‘32-bit .exe’ version).

2. Set up your **Bamboo home directory** — this is the directory where Bamboo will store its root configuration data. To do this, edit the file named `bamboo-init.properties` in the `<Bamboo installation directory>`.
directory>/atlassian-bamboo/WEB-INF/classes/ directory. In this file, insert the property "bamboo.home", with an absolute path to your Bamboo home directory. Your file should look something like this:

```
bamboo.home=C:/test/bamboo-home
```

Alternatively, you can specify an environment variable 'BAMBOO_HOME' which specifies the absolute path to your Bamboo home directory. Bamboo will check if an environment variable is defined.

iii. If you are going to use Bamboo remote agents, set the following in the bamboo-init.properties file in the <Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes directory:

```
bamboo.jms.broker.uri=tcp://localhost:54663
```

- Replace 'localhost' with the real host name or IP address of your Bamboo server.
- If port number 54663 is already in use, specify a different port number

2. Start Bamboo

   a) In the command line, change the directory to <Bamboo installation directory> and run the following command:

   ```
   bin\start-bamboo.bat
   ```

   b) In your Web browser, enter the following address: http://localhost:8085/

3. Configure Bamboo

   Follow the Setup Wizard to configure Bamboo. See Running the Setup Wizard.

Start using Bamboo

That's it! Your Bamboo site is accessible from a URL like this: http://<computer_name_or_IP_address>:<port>

Here's a few things that will help you get your team up and running:

- Set up Bamboo
- Running Bamboo as a service

Troubleshooting

Running into problems installing Bamboo?

If something is not working correctly after you have completed the steps above to install Bamboo, please check for known Bamboo issues and try troubleshooting your upgrade as described below:

- Check for known issues. Sometimes we find out about a problem with the latest version of Bamboo after we have released the software. In such cases we publish information about the known issues in the Bamboo Knowledge Base. Please check the known issues in the Bamboo Knowledge Base and follow the instructions to apply any necessary patches if necessary.

- Did you encounter a problem during the Bamboo installation? Please refer to the guide to troubleshooting upgrades in the Bamboo Knowledge Base.

- If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.

1. Download Bamboo

Download Bamboo from the Atlassian [download site](https://developer.atlassian.com/downloads). You can choose either the Windows Installer version (.exe) or a ZIP Archive (.zip).

> It is highly recommended to avoid placing the **Bamboo home directory** in any Windows security controlled directory, for example, C:\Program Files.

> **Installing using the Windows Installer**

i. Launch the Bamboo Windows installer to begin the installation wizard.

ii. The installer requires you to specify two directories:

- **Destination directory** — This is the directory where Bamboo's application files will be installed. The default is:
Installing using the Zip archive

i. Extract the files from the zip Archive to a `<Bamboo installation directory>` of your choice. By default, the root directory in your zip file is named "Bamboo".

**Warning: Some unzip programs cause errors**
Some archive-extract programs cause errors when unzipping the Bamboo archive file. We highly recommend that you use the free 7Zip archive-extract program (if in doubt, download the '32-bit .exe' version).

ii. Set up your **Bamboo home directory** — this is the directory where Bamboo will store its root configuration data. To do this, edit the file named `bamboo-init.properties` in the `<Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/` directory. In this file, insert the property "bamboo.home", with an absolute path to your Bamboo home directory. Your file should look something like this:

```properties
bamboo.home=C:/test/bamboo-home
```

Alternatively, you can specify an environment variable 'BAMBOO_HOME' which specifies the absolute path to your Bamboo home directory. Bamboo will check if an environment variable is defined.

iii. If you are going to use Bamboo remote agents, set the following in the `bamboo-init.properties` file in the `<Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/` directory:

```properties
bamboo.jms.broker.uri=tcp://localhost:54663
```

* Replace 'localhost' with the real host name or IP address of your Bamboo server.
* If port number 54663 is already in use, specify a different port number

2. Start Bamboo

   a) In the command line, change the directory to `<Bamboo installation directory>` and run the following command:

   ```bash
   bin\start-bamboo.bat
   ```

   b) In your Web browser, enter the following address: `http://localhost:8085/`

3. Configure Bamboo

   Follow the Setup Wizard to configure Bamboo. See Running the Setup Wizard.

**Start using Bamboo**

That's it! Your Bamboo site is accessible from a URL like this: `http://<computer_name_or_IP_address>:<port>`

Here's a few things that will help you get your team up and running:

- Setup Bamboo
- Running Bamboo as a service
Troubleshooting

Running into problems installing Bamboo?

If something is not working correctly after you have completed the steps above to install Bamboo, please check for known Bamboo issues and try troubleshooting your upgrade as described below:

- **Check for known issues.** Sometimes we find out about a problem with the latest version of Bamboo after we have released the software. In such cases we publish information about the known issues in the Bamboo Knowledge Base. Please check the known issues in the Bamboo Knowledge Base and follow the instructions to apply any necessary patches if necessary.

- **Did you encounter a problem during the Bamboo installation?** Please refer to the guide to troubleshooting upgrades in the Bamboo Knowledge Base.

- If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.

Installing Bamboo on Windows v6.1

In this guide we’ll run you through installing Bamboo with an external database on Windows.

On this page
1. Download Bamboo
2. Start Bamboo
3. Configure Bamboo
4. Start using Bamboo

Troubleshooting

Before you begin:

Before you install Bamboo, there are a few questions you need to answer.

Are you using a supported operating system?

Tell me more...

- Check the Supported platforms page for the version of Bamboo you are installing. This will give you info on supported operating systems, databases and browsers.

**Good to know:**

- We only support Bamboo on x86 and 64 bit x86 derived hardware platforms.
- You will need permissions for both the Bamboo installation and home directories.

Is your JAVA_HOME variable set correctly?

Tell me more...

Before you install Bamboo, check that you're running a supported Java version and that the JAVA_HOME environment variable is set correctly.

**Bamboo can only run with the JDK (not JRE).**

To check your Java version:

```
java -version
```

To check your JAVA_HOME variable is set correctly:
If you see a path to your Java installation directory, the \JAVA_HOME\ environment variable has been set correctly. If a path is not returned you'll need to set your \JAVA_HOME\ environment variable manually before installing Bamboo.

1. Download Bamboo

Download Bamboo from the Atlassian download site. You can choose either the Windows Installer version (.exe) or a ZIP Archive (.zip).

- It is highly recommended to avoid placing the Bamboo home directory in any Windows security controlled directory, for example, C:\Program Files.

   - Installing using the Windows Installer
     i. Launch the Bamboo Windows installer to begin the installation wizard.
     ii. The installer requires you to specify two directories:
        • Destination directory — This is the directory where Bamboo's application files will be installed. The default is:
          ```
          C:\Program Files\Bamboo
          ```
        • Bamboo home directory — This is the directory where Bamboo will store its configuration data. If the directory you specify doesn't exist, Bamboo will create the directory when it launches. The default is:
          ```
          C:\Users<current-user>\Bamboo-home
          ```

          Ensure that the Bamboo home directory is not located inside the <Bamboo installation directory>.

   - Installing using the Zip archive
     i. Extract the files from the zip Archive to a <Bamboo installation directory> of your choice. By default, the root directory in your zip file is named "Bamboo".

        Warning: Some unzip programs cause errors
        Some archive-extract programs cause errors when unzipping the Bamboo archive file. We highly recommend that you use the free 7Zip archive-extract program (if in doubt, download the '32-bit .exe' version).

     ii. Set up your Bamboo home directory — this is the directory where Bamboo will store its root configuration data. To do this, edit the file named bamboo-init.properties in the <Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/ directory. In this file, insert the property "bamboo.home", with an absolute path to your Bamboo home directory. Your file should look something like this:

          ```
          bamboo.home=C:/test/bamboo-home
          ```

        Alternatively, you can specify an environment variable 'BAMBOO_HOME' which specifies the absolute path to your Bamboo home directory. Bamboo will check if an environment variable is defined.

     iii. If you are going to use Bamboo remote agents, set the following in the bamboo-init.properties file in the <Bamboo installation directory>/atlassian-bamboo/WEB-INF/classes/ directory:

          ```
          bamboo.jms.broker.uri=tcp://localhost:54663
          ```
Replace 'localhost' with the real host name or IP address of your Bamboo server.
If port number 54663 is already in use, specify a different port number

2. Start Bamboo
   a) In the command line, change the directory to \Bamboo installation directory\ and run the following command:
      `\bin\start-bamboo.bat`
   b) In your Web browser, enter the following address: `http://localhost:8085/`

3. Configure Bamboo
   Follow the Setup Wizard to configure Bamboo. See Running the Setup Wizard.

Start using Bamboo
That's it! Your Bamboo site is accessible from a URL like this: http://<computer_name_or_IP_address>:<port>

Here's a few things that will help you get your team up and running:

- Set up Bamboo
- Running Bamboo as a service

Troubleshooting

Running into problems installing Bamboo?
If something is not working correctly after you have completed the steps above to install Bamboo, please check for known Bamboo issues and try troubleshooting your upgrade as described below:

- **Check for known issues.** Sometimes we find out about a problem with the latest version of Bamboo after we have released the software. In such cases we publish information about the known issues in the Bamboo Knowledge Base. Please check the known issues in the Bamboo Knowledge Base and follow the instructions to apply any necessary patches if necessary.

- **Did you encounter a problem during the Bamboo installation?** Please refer to the guide to troubleshooting upgrades in the Bamboo Knowledge Base.

- If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.

Running the Setup Wizard
When you launch Bamboo for the first time, the Bamboo setup wizard will display. The wizard will lead you through the Bamboo settings that you need to configure before you can start using it.

Before you begin
If you are currently using Atlassian's Crowd with Bamboo and wish to import existing data into Bamboo (see Step 5. Starting Data below), you will need to disable Crowd before starting the Setup Wizard. To do this, go to Administration > User Repositories (under 'Security') and choose Local users and groups.

You can then re-enable Crowd and restart Bamboo at the completion of the Setup Wizard.
Step 1. License Details and Setup Method

You must have a valid Bamboo license (evaluation or commercial) to use Bamboo. You can generate your own Bamboo evaluation license from your MyAtlassian self-service account here.

Once you have entered a valid license key, you can choose which setup method you prefer for your Bamboo installation:

- **Express Installation** — use this method if you are evaluating or demonstrating Bamboo.
  - The 'Express Installation' method requires only a minimum of configuration information. It sets up Bamboo with default settings and an embedded database (H2).
  - If you choose the 'Express Installation' method you can skip to Step 6. Set Up Administrator User below.

- **Custom Installation** — use this method if you are setting up a production instance of Bamboo.
  - The 'Custom Installation' method takes longer, but allows you to configure Bamboo with an external database, customize the default settings, and/or initialize the server with your own data.
  - If you choose, the 'Custom Installation' method, proceed to Step 2. General Configuration below.

**On this page:**
- Step 1. License Details and Setup Method
- Step 2. General Configuration
- Step 3. Choose a Database Configuration
- Step 4. Database Configuration
- Step 5. Starting Data
- Step 6. Set Up Administrator User

**Related pages:**
- Installing Bamboo on Linux
- Installing Bamboo on Mac OS X
- Installing Bamboo on Windows

**Screenshot: License Details and Setup Method**

This step applies to the 'Custom Installation' method only.

On this page you specify a number of Bamboo server settings, such as the address of the server, where data is stored and the message broker used to communicate with remote agents.

You may find it simplest to keep the default settings for the three directory settings, in the table. For more information please see Location

<td>See <a href="#">Specifying Bamboo's Title</a></td>
</tr>
<tr>
<td>Base URL</td>
<td>See <a href="#">Specifying Bamboo's URL</a></td>
</tr>
<tr>
<td>Configuration Directory</td>
<td>The location for Bamboo configuration files.</td>
</tr>
<tr>
<td>Build Data Directory</td>
<td>The location for Bamboo project data files.</td>
</tr>
<tr>
<td>Build Working Directory</td>
<td>The location of project files checked out from source control.</td>
</tr>
<tr>
<td>Broker URL</td>
<td>Only visible if you are permitted remote agents under your Bamboo license. The URL of the embedded messaging broker that Bamboo sets up to communicate with its remote build agents. This URL will be written to <code>bamboo.cfg.xml</code> as a property. You can update this file if you want to change your Broker URL.</td>
</tr>
<tr>
<td></td>
<td>- Replace <code>localhost</code> with the real host name or IP address of your Bamboo server. You should not use <code>localhost</code> as the host name in the Broker URL, as remote agents are provided with the Broker URL on startup and use it to communicate to the server.</td>
</tr>
<tr>
<td></td>
<td>- If port number 54663 is already in use, specify a different port number.</td>
</tr>
<tr>
<td>Broker client URL</td>
<td>The URL used by agents to connect to the broker. This URL will be written to <code>bamboo.cfg.xml</code> as a property. You can update this file if you want to change your Broker URL. The default includes an actual IP of the Bamboo server. Specify if the default IP is not reachable from the agents.</td>
</tr>
</tbody>
</table>

*Screenshot: General Configuration*
Step 3. Choose a Database Configuration

ℹ️ This step applies to the 'Custom Installation' method only.

Picking a database configuration is an important choice. If you pick the 'Embedded Database' configuration, you do not have to set up a database. However, the embedded H2 database is only suitable for evaluation purposes. You will need to move to an external database, if you decide to deploy Bamboo in production at a later stage (as described in Moving your Bamboo data to a different database).

Choose one of the following:

- **Embedded** — Choose this for quick and easy first-time installation of Bamboo. This option is suitable for evaluation purposes only. Skip to Step 5. Starting Data.

- **External** — Choose this if you wish to use an external database. Proceed to Step 4. Database Configuration below.

*Screenshot: Choose a Database Configuration*
Step 4. Database Configuration

This step applies to the ‘Custom Installation’ method only.

If you selected ‘External Database’ in Step 3, you will need to provide the configuration details for your database. Please see Connecting Bamboo to an external database for further instructions.

Screenshot: Database Configuration

Step 5. Starting Data

This step applies to the ‘Custom Installation’ method only.

Screenshot: Starting Data
On this page you specify how Bamboo will populate the 'home directory' that you set up when you installed Bamboo.

Choose one of the following:

- **Create new Bamboo home** — choose this if you are performing a normal installation or upgrade.
- **Import existing data** — only choose this under exceptional circumstances, e.g. if you are connecting Bamboo to a different database, or moving your pre-existing Bamboo installation to a different server. Avoid importing backups from different versions of Bamboo.

### Step 6. Set Up Administrator User

The final step of the setup wizard is to enter the details of the first registered user for the Bamboo system. This user will have global administrative privileges over the entire installation of Bamboo and should not be removed.

Once you have entered the details for your administrator user, click **Finish**. The Bamboo dashboard will be displayed.

Congratulations, you have successfully set up Bamboo!

**Screenshot: Set Up Administrator User**

### Running the Setup Wizard v5.14

When you launch Bamboo for the first time, the Bamboo setup wizard will display. The wizard will lead you through the Bamboo settings that you need to configure before you can start using it.

**Before you begin**

If you are currently using Atlassian's Crowd with Bamboo and wish to import existing data into Bamboo (see Step 5. Starting Data below), you will need to disable Crowd before starting the Setup Wizard. To do this, go to Administration > User Repositories (under 'Security') and choose Local users and groups.

You can then re-enable Crowd and restart Bamboo at the completion of the Setup Wizard.

### Step 1. License Details and Setup Method

You must have a valid Bamboo license (evaluation or commercial) to use Bamboo. You can generate your own Bamboo evaluation license from your MyAtlassian self-service account here. If you have any problems with this, please contact our Customer Advocates.

Once you have entered a valid license key, you can choose which setup method you prefer for your Bamboo installation:

**Express Installation** — we recommend that you choose this method if you are evaluating or demonstrating Bamboo.

- The 'Express Installation' method requires only a minimum of configuration information. It sets up Bamboo with default settings and an embedded database (HSQL).
- If you choose the 'Express Installation' method you can skip to Step 6. Set Up Administrator User below.
Custom Installation — we recommend that you choose this method if you are setting up a production instance of Bamboo.

- The 'Custom Installation' method takes longer, but allows you to configure Bamboo with an external database, customize the default settings, and/or initialize the server with your own data.
- If you choose the 'Custom Installation' method, proceed to Step 2. General Configuration below.

**Screenshot: License Details and Setup Method**

![License Details and Setup Method](image)

**Step 2. General Configuration**

*This step applies to the 'Custom Installation' method only.*

On this page you specify a number of Bamboo server settings, such as the address of the server, where data is stored and the message broker used to communicate with remote agents.

You may find it simplest to keep the default settings for the three directory settings, in the table. For more information please see **Locating important directories and files**.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>See Specifying Bamboo's Title</td>
</tr>
<tr>
<td>Base URL</td>
<td>See Specifying Bamboo's URL</td>
</tr>
<tr>
<td>Configuration Directory</td>
<td>The location for Bamboo configuration files.</td>
</tr>
<tr>
<td>Build Data Directory</td>
<td>The location for Bamboo project data files.</td>
</tr>
<tr>
<td>Documentation for Bamboo 6.7</td>
<td></td>
</tr>
<tr>
<td>-----------------------------</td>
<td></td>
</tr>
</tbody>
</table>

**Build Working Directory**

The location of project files checked out from source control.

**Broker URL**

Only visible if you are permitted remote agents under your Bamboo license.

The URL of the embedded messaging broker that Bamboo sets up to communicate with its remote build agents. This URL will be written to `bamboo.cfg.xml` as a property. You can update this file if you want to change your Broker URL.

- Replace `localhost` with the real host name or IP address of your Bamboo server. You should not use `localhost` as the host name in the Broker URL, as remote agents are provided with the Broker URL on startup and use it to communicate to the server.
- If port number 54663 is already in use, specify a different port number.

**Broker client URL**

The URL used by agents to connect to the broker. This URL will be written to `bamboo.cfg.xml` as a property. You can update this file if you want to change your Broker URL.

The default includes an actual IP of the Bamboo server. Specify if the default IP is not reachable from the agents.

**Screenshot: General Configuration**

![General configuration](image)

**Step 3. Choose a Database Configuration**

*This step applies to the 'Custom Installation' method only.*
Picking a database configuration is an important choice. If you pick the ‘Embedded Database’ configuration, you do not have to set up a database. However, the embedded HSQL database is only suitable for evaluation purposes. You will need to move to an external database, if you decide to deploy Bamboo in production at a later stage (as described in Moving your Bamboo data to a different database).

Choose one of the following:

- **Embedded Database** — Choose this for quick and easy first-time installation of Bamboo. This option is suitable for evaluation purposes only. Skip to Step 5. Starting Data.

- **External Database** — Choose this if you wish to use an external database. Proceed to Step 4. Database Configuration below.

**Screenshot: Choose a Database Configuration**

### Step 4. Database Configuration

ℹ️ This step applies to the ‘Custom Installation’ method only.

If you selected ‘External Database’ in Step 3, you will need to provide the configuration details for your database. Please see Connecting Bamboo to an external database for further instructions.

**Screenshot: Database Configuration**

### Step 5. Starting Data

ℹ️ This step applies to the ‘Custom Installation’ method only.
On this page you specify how Bamboo will populate the 'home directory' that you set up when you installed Bamboo.

Choose one of the following:

- **Create new Bamboo home** — choose this if you are performing a normal installation or upgrade.
- **Import existing data** — only choose this under exceptional circumstances, e.g. if you are connecting Bamboo to a different database, or moving your pre-existing Bamboo installation to a different server. Avoid importing backups from different versions of Bamboo.

**Step 6. Set Up Administrator User**

The final step of the setup wizard is to enter the details of the first registered user for the Bamboo system. This user will have global administrative privileges over the entire installation of Bamboo and should not be removed.

Once you have entered the details for your administrator user, click Finish. The Bamboo dashboard will be displayed.

Congratulations, you have successfully set up Bamboo!

**Running the Setup Wizard v5.15**

When you launch Bamboo for the first time, the Bamboo setup wizard will display. The wizard will lead you through the Bamboo settings that you need to configure before you can start using it.

**Before you begin**

If you are currently using Atlassian's Crowd with Bamboo and wish to import existing data into Bamboo (see Step 5. Starting Data below), you will need to disable Crowd before starting the Setup Wizard. To do this, go to Administration > User Repositories (under 'Security') and choose Local users and groups.

You can then re-enable Crowd and restart Bamboo at the completion of the Setup Wizard.

**Step 1. License Details and Setup Method**

You must have a valid Bamboo license (evaluation or commercial) to use Bamboo. You can generate your own Bamboo evaluation license from your MyAtlassian self-service account here.
Once you have entered a valid license key, you can choose which setup method you prefer for your Bamboo installation:

- **Express Installation** — use this method if you are evaluating or demonstrating Bamboo.
  - The ‘Express Installation’ method requires only a minimum of configuration information. It sets up Bamboo with default settings and an embedded database (HSQL).
  - If you choose the ‘Express Installation’ method you can skip to Step 6. Set Up Administrator User below.

On this page:

- Step 1. License Details and Setup Method
- Step 2. General Configuration
- Step 3. Choose a Database Configuration
- Step 4. Database Configuration
- Step 5. Starting Data
- Step 6. Set Up Administrator User

**Related pages:**

- Installing Bamboo on Linux
- Installing Bamboo on Mac OS X
- Installing Bamboo on Windows

**Custom Installation** — use this method if you are setting up a production instance of Bamboo.

- The ‘Custom Installation’ method takes longer, but allows you to configure Bamboo with an external database, customize the default settings, and/or initialize the server with your own data.
- If you choose, the 'Custom Installation' method, proceed to Step 2. General Configuration below.

**Screenshot: License Details and Setup Method**

Please enter your license information and choose a setup method below to complete the installation of Bamboo.

**Select setup method**

- **Express installation**
  - Installs Bamboo with default settings and an embedded database. Recommended if you are evaluating or demonstrating Bamboo, as it will get you up and running as quickly as possible.

- **Custom installation**
  - Installs Bamboo but allows you to configure Bamboo with an external database, customize the default settings, and/or initialise the server with your own data. Recommended if you are setting up a production instance.

**Step 2. General Configuration**

ℹ️ This step applies to the ‘Custom Installation’ method only.

On this page you specify a number of Bamboo server settings, such as the address of the server, where data is stored and the message broker used to communicate with remote agents.

⚠️ You may find it simplest to keep the default settings for the three directory settings, in the table. For more information please see **Locating important directories and files**.

The default includes an actual IP of the Bamboo server. Specify if the default IP is not reachable from the agents.</td>
</tr>
</tbody>
</table>

**Screenshot: General Configuration**

![General configuration screenshot](image-url)

- **What is the title of this Bamboo Instance?**
  - Name: Atlassian Bamboo

- **What is the server's address?**
  - Base URL: `http://127.0.0.1:8085`

- **System paths and directories**
  - Configuration directory: `/home/nathan/Desktop/Bamboo1/Atlassian-Bamboo-5.1-m2/~/Desktop/bam1`
  - Build directory: `/home/nathan/Desktop/Bamboo1/Atlassian-Bamboo-5.1-m2/~/Desktop/bam1`
  - Build working directory: `/home/nathan/Desktop/Bamboo1/Atlassian-Bamboo-5.1-m2/~/Desktop/bam1`
  - Artifacts directory: `/home/nathan/Desktop/Bamboo1/Atlassian-Bamboo-5.1-m2/~/Desktop/bam1`

- **Remote agent communication**
  - Broker URL: `tcp://0.0.0.0:54663?wireFormat.maxActivityDuration=300000`

  The URL on which your messaging broker will be set up. The messaging broker is used for communication with Bamboo remote agents. Bamboo remote agents will also use this path to communicate back to this Server.
Step 3. Choose a Database Configuration

*This step applies to the 'Custom Installation' method only.*

Picking a database configuration is an important choice. If you pick the 'Embedded Database' configuration, you do not have to set up a database. However, the embedded HSQL database is only suitable for evaluation purposes. You will need to move to an external database, if you decide to deploy Bamboo in production at a later stage (as described in Moving your Bamboo data to a different database).

Choose one of the following:

- **Embedded** — Choose this for quick and easy first-time installation of Bamboo. This option is suitable for evaluation purposes only. Skip to Step 5. Starting Data.
- **External** — Choose this if you wish to use an external database. Proceed to Step 4. Database Configuration below.

**Screenshot: Choose a Database Configuration**

![Choose a database configuration](image1)

Step 4. Database Configuration

*This step applies to the 'Custom Installation' method only.*

If you selected 'External Database' in Step 3, you will need to provide the configuration details for your database. Please see Connecting Bamboo to an external database for further instructions.

**Screenshot: Database Configuration**

![Choose how you wish Bamboo to connect to your database](image2)
Step 5. Starting Data

This step applies to the ‘Custom Installation’ method only.

On this page you specify how Bamboo will populate the ‘home directory’ that you set up when you installed Bamboo.

Choose one of the following:

- Create new Bamboo home — choose this if you are performing a normal installation or upgrade.
- Import existing data — only choose this under exceptional circumstances, e.g. if you are connecting Bamboo to a different database, or moving your pre-existing Bamboo installation to a different server. Avoid importing backups from different versions of Bamboo.

Step 6. Set Up Administrator User

The final step of the setup wizard is to enter the details of the first registered user for the Bamboo system. This user will have global administrative privileges over the entire installation of Bamboo and should not be removed.

Once you have entered the details for your administrator user, click Finish. The Bamboo dashboard will be displayed.

Congratulations, you have successfully set up Bamboo!

Running the Setup Wizard v6.3

When you launch Bamboo for the first time, the Bamboo setup wizard will display. The wizard will lead you through the Bamboo settings that you need to configure before you can start using it.

Before you begin

If you are currently using Atlassian’s Crowd with Bamboo and wish to import existing data into Bamboo (see Step 5. Starting Data below), you will need to disable Crowd before starting the Setup Wizard. To do this, go to Administration > User Repositories (under ‘Security’) and choose Local users and groups.
Step 1. License Details and Setup Method

You must have a valid Bamboo license (evaluation or commercial) to use Bamboo. You can generate your own Bamboo evaluation license from your MyAtlassian self-service account here.

Once you have entered a valid license key, you can choose which setup method you prefer for your Bamboo installation:

- **Express Installation** — use this method if you are evaluating or demonstrating Bamboo.
  - The 'Express Installation' method requires only a minimum of configuration information. It sets up Bamboo with default settings and an embedded database (H2).
  - If you choose the 'Express Installation' method you can skip to Step 6. Set Up Administrator User below.

- **Custom Installation** — use this method if you are setting up a production instance of Bamboo.
  - The 'Custom Installation' method takes longer, but allows you to configure Bamboo with an external database, customize the default settings, and/or initialize the server with your own data.
  - If you choose the 'Custom Installation' method, proceed to Step 2. General Configuration below.

### Bamboo remote agent installation guide

**Before you begin**

Before you begin installing remote agents, there are a few questions you need to answer.

- **Do you need to install a remote agent?**
  
  See [Agents and capabilities](https://<your-bamboo-url>/admin/agents) to understand how remote agents interact with your Bamboo server.

- **Do you have sufficient agent licenses?**
  
  See [Bamboo licensing](https://<your-bamboo-url>/admin/licensing) for details.

- **Does your system meet the minimum requirements?**
  
  See [Supported platforms](https://<your-bamboo-url>/admin/platforms).

- **Do you have a supported version of Java installed on the agent machine?**
  
  See [Supported platforms](https://<your-bamboo-url>/admin/platforms).

- **Are you upgrading your version of Bamboo?**

  If yes, your remote-agents will be upgraded automatically along with Bamboo.

Note that you can run multiple Bamboo agents on the same machine – you just need to provide a separate home.
1. Enable remote agent support

1. Click the icon in the Bamboo header and choose Overview.
2. In the left-hand panel, under Build Resources, click Agents.
3. Click either Enable Remote Agent Support or Disable Remote Agent Support.

Read more about enabling and disabling remote agent support here.

2. Download and install the remote agent

1. Create a directory on the agent machine (e.g. bamboo-agent-home) to serve as the Bamboo agent home for the remote agent.
2. Click the icon in the Bamboo header and choose Overview.
3. In the left-hand panel, under Build Resource, click Agents in the left panel.
   The 'Agents' screen displays showing the lists of all local agents and all remote agents that currently exist on your Bamboo system.
4. If not already enabled, click the Enable remote agent support link
5. Click Install Remote Agent. The 'Installing a remote agent' screen will display
6. Click DOWNLOAD Remote Agent JAR and save the JAR file to the directory on the agent machine that you created above.
7. Copy the command under 'Running a Remote Agent' to the clipboard for use in Step 3 that follows.

3. Launch the remote agent

Once installed, run the remote agent by executing the command line obtained above. This command will look something like this:

```
java -jar atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
http://bamboo-host-server:8085/bamboo/agentServer/
```

Where X.X represents your Bamboo version number.

If you are having issues launching the agent, then take a look at our troubleshooting guide.

The name of the jar file, for example, atlassian-bamboo-agent-installer-5.4-SNAPSHOT.jar, will vary depending on the version of Bamboo you are running.

You can run the remote agent with a number of additional command line parameters. Configuration options include remote agent data storage, capability detection and logging, suppression of self-signed certificate and running without the Remote Agent Supervisor or with different start-up commands.

See Additional remote agent options for more information.

4. Configure the remote agent's capabilities

All remote agents feature a capability that can be defined. Examples include an executable, such as Maven, a JDK, a DVCS client or a custom capability. They typically define the path to an executable that has already been installed, and must be defined in Bamboo before Bamboo or its agents can make use of them.

Capabilities can be defined specifically for an agent, or shared between all local or all remote agents.

See Configuring capabilities for more on defining capabilities.

Configuring remote agent capabilities using bamboo-capabilities.properties

You can define the capabilities for a specific remote agent by using a configuration file on the agent machine. When the Bamboo agent starts
To configure remote agent capabilities:

We are aware of an issue that prevents a remote agent capability from being updated once it has been added using the `bamboo-capabilities.properties` file. If you choose to add capabilities with the `bamboo-capabilities.properties` file, you will only be able to update them by deleting the capability in Bamboo and restarting the remote agent. Please see BAM-4213 for further details.
1. Shut down the remote agent, if it is running.
2. Create a file named `bamboo-capabilities.properties` in the current runtime directory (i.e. `<bamboo-agent-home>/bin`) on the agent machine.
3. Edit the `bamboo-capabilities.properties` file to add capabilities. You need to use the formats shown below:
   Notes:
   - Use `'\' to escape spaces, periods and backslashes (`\`).
   - All capabilities, other than custom capabilities, should start with `'system'`.

   **JDK capabilities**
   ```
   system.jdk.JDK\ <jdk number>=<jdk location>
   ```
   Examples:
   ```
   system.jdk.JDK\ 1.6=/System/Library/Frameworks/JavaVM.framework/Versions/1.6
   system.jdk.JDK\ 1.6=C:\Program Files\Java\jdk6.0.17
   ```

   **Executable capabilities**
   ```
   system.builder.<executable type>.<executable label>=<executable path>
   ```
   Examples:
   ```
   system.builder.ant.Ant=/opt/apache-ant-1.7.1
   system.builder.maven.Maven\ 1=/opt/maven-1.0.2
   system.builder.mvn2.Maven\ 2=/opt/maven-2.0
   system.builder.node.Node.js\ 0.12=/opt/node-0.12/bin/node
   ```

   **Version control capabilities**
   ```
   system.<DVCS>.executable=<DVCS command location>
   ```
   Examples:
   ```
   system.git.executable=/usr/bin/git
   system.hg.executable=/usr/bin/hg
   ```

   **Perforce capabilities**
   ```
   system.p4Executable=<perforce executable location>
   ```
   Example:
   ```
   system.p4Executable=/usr/bin/p4
   ```

   **Custom capabilities**
   ```
   <custom capability name>=<custom capability value>
   ```
   Example:
   ```
   system.os=osx
   ```

4. Save your changes to the `bamboo-capabilities.properties` file.
5. Start up your remote agent. The capabilities defined in the `bamboo-capabilities.properties` file will be configured for your agent.
**Configuring remote agent capabilities using bamboo-capabilities.properties v5.14**

You can define the capabilities for a specific remote agent by using a configuration file on the agent machine. When the Bamboo agent starts up, it will look in the current runtime directory (i.e. `<bamboo-agent-home>/bin`) for a file named `bamboo-capabilities.properties`. The capabilities defined in that file will then be published for the Bamboo agent after registering.

We are aware of an issue that prevents a remote agent capability from being updated once it has been added using the `bamboo-capabilities.properties` file. If you choose to add capabilities with the `bamboo-capabilities.properties` file, you will only be able to update them by deleting the capability in Bamboo and restarting the remote agent. Please see BAM-4213 for further details.

To configure remote agent capabilities:

1. Shut down the remote agent, if it is running.
2. Create a file named `bamboo-capabilities.properties` in the current runtime directory (i.e. `<bamboo-agent-home>/bin`) on the agent machine.
3. Edit the `bamboo-capabilities.properties` file to add capabilities. You need to use the formats shown below:

   **Notes:**
   - Use `\` to escape spaces, periods and backslashes (`\`).
   - All capabilities, other than custom capabilities, should start with `system`.

<table>
<thead>
<tr>
<th>JDK capabilities</th>
<th>system.jdk.JDK\ <code>&lt;jdk number&gt;=&lt;jdk location&gt;</code></th>

```

Custom capabilities

```
<custom capability name>=<custom capability value>
```

Example:
```
system.os=osx
```

4. Save your changes to the `bamboo-capabilities.properties` file.
5. Start up your remote agent. The capabilities defined in the `bamboo-capabilities.properties` file will be configured for your agent.

Configuring remote agent capabilities using `bamboo-capabilities.properties` v6.1

You can define the capabilities for a specific remote agent by using a configuration file on the agent machine. When the Bamboo agent starts up, it will look in the current runtime directory (i.e., `<bamboo-agent-home>/bin`) for a file named `bamboo-capabilities.properties`. The capabilities defined in that file will then be published for the Bamboo agent after registering.

We are aware of an issue that prevents a remote agent capability from being updated once it has been added using the `bamboo-capabilities.properties` file. If you choose to add capabilities with the `bamboo-capabilities.properties` file, you will only be able to update them by deleting the capability in Bamboo and restarting the remote agent. Please see BAM-4213 for further details.

To configure remote agent capabilities:
1. Shut down the remote agent, if it is running.
2. Create a file named `bamboo-capabilities.properties` in the current runtime directory (i.e. `<bamboo-agent-home>/bin`) on the agent machine.
3. Edit the `bamboo-capabilities.properties` file to add capabilities. You need to use the formats shown below:
   Notes:
   - Use `\` to escape spaces, periods and backslashes (`\`).
   - All capabilities, other than custom capabilities, should start with `system`.

**JDK capabilities**

```
system.jdk.JDK\ <jdk number>=<jdk location>
```

Examples:

```
system.jdk.JDK\ 1.6=/System/Library/Frameworks/JavaVM.framework/Versions/1.6
system.jdk.JDK\ 1.6=C:\Program Files\Java\jdk6.0.17
```

**Executable capabilities**

```
system.builder.<executable type>.<executable label>=<executable path>
```

Examples:

```
system.builder.ant.Ant=/opt/apache-ant-1.7.1
system.builder.maven.Maven\ 1=/opt/maven-1.0.2
system.builder.mvn2.Maven\ 2=/opt/maven-2.0
system.builder.node.Node.js\ 0.12=/opt/node-0.12/bin/node
```

**Version control capabilities**

```
system.<DVCS>.executable=<DVCS command location>
```

Examples:

```
system.git.executable=/usr/bin/git
system.hg.executable=/usr/bin/hg
```

**Perforce capabilities**

```
system.p4Executable=<perforce executable location>
```

Example:

```
system.p4Executable=/usr/bin/p4
```

**Custom capabilities**

```
<custom capability name>=<custom capability value>
```

Example:

```
system.os=osx
```

4. Save your changes to the `bamboo-capabilities.properties` file.
5. Start up your remote agent. The capabilities defined in the `bamboo-capabilities.properties` file will be configured for your agent.

---

Legacy remote agent installation guide

---

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
If you have implemented your own remote agent service wrapper or have problems with the service wrapper used by the remote agent supervisor in Bamboo, you can install the legacy remote agent (pre-Bamboo 2.2) which does not have a service wrapper.

### Before you begin:
- **Not sure whether to install a Remote Agent?** See [About Agents](#) to understand how Remote Agents interact with your Bamboo server.
- Ensure that you have specified the Broker URL, as described in the [Bamboo Setup Wizard](#).
- Do you have sufficient Agent licenses? See [Bamboo licensing](#) for details.
- Have you enabled the creation of Remote Agents, as described in [Disabling and enabling remote agents support](#).
- Ensure that you have Java Runtime Environment 5.0 or later installed on the agent machine.

### Step 1. Download and install the Legacy Remote Agent

1. Create a directory on the agent machine (e.g. `bamboo-agent-home`), to serve as the "Bamboo agent home" for the remote agent.
2. On your Bamboo server, click **Administration** in the top menu.
3. Click **Agents** in the left navigation panel. This will display the 'Agents' screen, showing lists of all Local Agents and all Remote Agents that currently exist in your Bamboo system.
4. Click **Install Remote Agent**. The 'Install Remote Agent' screen will be displayed.
5. Click **bamboo-agent.jar** under the ‘Running the agents without the service wrapper’ section and save the JAR file to the directory you created in step 1.1.

   **Note that if you configure the capabilities of the remote agent** using a `bamboo-capabilities.properties` file, that file should be located in the same directory as the JAR file (that is, `bamboo-agent-home` in the above instructions).

### Step 2. Launch the Remote Agent

Once installed, you can run the remote agent by executing the command line obtained in the previous step. This command will look something like the following:

```bash
java -jar bamboo-agent-2.0-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer/
```

You may wish to configure the remote agent machine to start the Bamboo remote agent automatically when the machine boots. Please consult your operating system documentation for instructions on how to do this.

You can also choose to run the remote agent with different command line parameters, to change where the remote agent stores its data or suppress the self-signed certificate of the server.

#### Changing where the remote agent stores its data

By default, the remote agent will store its data in a directory called `bamboo-agent-home`. If you wish to specify a different directory, add the following command line parameter:

```bash
-Dbamboo.home=RemoteAgentHome
```

where `RemoteAgentHome` is the path to the Bamboo agent home directory you created in step 1.1. Your command line will look something like this:

```bash
java -Dbamboo.home=RemoteAgentHome -jar bamboo-agent-2.0-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer/
```

#### Suppressing the self-signed certificate of the server

If your Bamboo server uses SSL (https) with a self-signed certificate, you will need to carry out one of the following two options:

- **Add the parameter** `-Dbamboo.agent.ignoreServerCertName=true` to the remote agent's command line, for example:
  ```bash
  java -Dbamboo.agent.ignoreServerCertName=true -jar bamboo-agent-2.0-SNAPSHOT.jar http://bamboo-host-server:8085/agentServer/
  ```
  Please be aware that this reduces the security of your configuration, as the identity of your Bamboo server will not be authenticated by the remote agent.
- **Use the keytool utility to add the self-signed certificate to the trusted certificates in your keystore.** This is a more secure method.
option, but is complex to set up. For detailed instructions of how to do this, please refer to the relevant Oracle documentation.

Step 3. Configure the Remote Agent’s Capabilities

Please see Configuring capabilities.

.Bamboo remote agent installation guide v5.14
This page describes how to install the Bamboo Remote Agent manually.

Before you begin:

- Do you need to install a remote agent? See Agents and capabilities to understand how remote agents interact with your Bamboo server.
- Do you have sufficient agent licenses? See Bamboo licensing for details.
- Does your system meet the minimum requirements? See Supported platforms.
- Do you have a supported version of Java installed on the agent machine? See Supported platforms.
- Are you upgrading your version of Bamboo? If yes, your remote-agents will be upgraded automatically along with Bamboo.

Note that you can run multiple Bamboo agents on the same machine – you just need to provide a separate home directory for each agent installation.

Step 1. Enable remote agent support

1. Click the icon in the Bamboo header and choose Overview.
2. Click Agents (under ‘Build Resources’)
3. Click either Enable Remote Agent Support or Disable Remote Agent Support.

Read more about enabling and disabling remote agent support here.

On this page:

| Step 1. Enable remote agent support |
| Step 2. Download and install the remote agent |
| Step 3. Launch the remote agent |
| Step 4. Configure the remote agent's capabilities |

Related pages:

- Configuring remote agent capabilities using bamboo-capabilities.properties
- Implementing a remote agent service wrapper
- Legacy remote agent installation guide
- Enabling creation of remote agents
- Specifying a Broker URL

Step 2. Download and install the remote agent

1. Create a directory on the agent machine (e.g. bamboo-agent-home) to serve as the Bamboo agent home for the remote agent.
2. Click the icon in the Bamboo header and choose Overview.
3. Click Agents in the left panel (Under Build Resources). This will display the ‘Agents’ screen, showing lists of all local agents and all remote agents that currently exist on your Bamboo system.
4. If not already enabled, click the Enable remote agent support link
5. Click Install Remote Agent. The ‘Installing a remote agent’ screen will display
6. Click DOWNLOAD Remote Agent JAR and save the JAR file to the directory on the agent machine that you created above.
7. Copy the command under ‘Running a Remote Agent’ to the clipboard for use in Step 3 that follows.

Step 3. Launch the remote agent

Once installed, run the remote agent by executing the command line obtained above. This command will look something like this:
java -jar atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
http://bamboo-host-server:8085/bamboo/agentServer/

Where X.X represents your Bamboo version number.

If you are having issues launching the agent, then take a look at our troubleshooting guide.

The name of the jar file, for example, atlassian-bamboo-agent-installer-5.4-SNAPSHOT.jar, will vary depending on the version of Bamboo you are running.

You can run the remote agent with a number of additional command line parameters. Configuration options include remote agent data storage, capability detection and logging, suppression of self-signed certificate and running without the Remote Agent Supervisor or with different start-up commands.

See Additional remote agent options for more information.

Step 4. Configure the remote agent's capabilities

All remote agents feature a capability that can be defined. Examples include an executable, such as Maven, a JDK, a DVCS client or a custom capability. They typically define the path to an executable that has already been installed, and must be defined in Bamboo before Bamboo or its agents can make use of them.

Capabilities can be defined specifically for an agent, or shared between all local or all remote agents.

Please see Configuring capabilities for more on defining capabilities.

1. Enable remote agent support

   1. Click the icon in the Bamboo header and choose Overview.
   2. In the left-hand panel, under Build Resources, click Agents.
   3. Click either Enable Remote Agent Support or Disable Remote Agent Support.

   Related pages:
   - Configuring remote agent capabilities using bamboo-capabilities.properties
   - Implementing a remote agent service wrapper
   - Legacy remote agent installation guide
   - Enabling creation of remote agents
   - Specifying a Broker URL
Read more about enabling and disabling remote agent support here.

2. Download and install the remote agent

1. Create a directory on the agent machine (e.g. bamboo-agent-home) to serve as the Bamboo agent home for the remote agent.
2. Click the icon in the Bamboo header and choose Overview.
3. In the left-hand panel, under Build Resource, click Agents in the left panel.
   The 'Agents' screen displays showing the lists of all local agents and all remote agents that currently exist on your Bamboo system.
4. If not already enabled, click the Enable remote agent support link.
5. Click Install Remote Agent. The 'Installing a remote agent' screen will display.
6. Click DOWNLOAD Remote Agent JAR and save the JAR file to the directory on the agent machine that you created above.
7. Copy the command under 'Running a Remote Agent' to the clipboard for use in Step 3 that follows.

3. Launch the remote agent

Once installed, run the remote agent by executing the command line obtained above. This command will look something like this:

```
java -jar atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
http://bamboo-host-server:8085/bamboo/agentServer/
```

Where X.X represents your Bamboo version number.

If you are having issues launching the agent, then take a look at our troubleshooting guide.

4. Configure the remote agent’s capabilities

All remote agents feature a capability that can be defined. Examples include an executable, such as Maven, a JDK, a DVCS client or a custom capability. They typically define the path to an executable that has already been installed, and must be defined in Bamboo before Bamboo or its agents can make use of them.

Capabilities can be defined specifically for an agent, or shared between all local or all remote agents.

See Configuring capabilities for more on defining capabilities.

.Bamboo remote agent installation guide v6.0

Before you begin

Before you begin installing remote agents, there are a few questions you need to answer.

<table>
<thead>
<tr>
<th>Do you need to install a remote agent?</th>
<th>See Agents and capabilities to understand how remote agents interact with your Bamboo server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do you have sufficient agent licenses?</td>
<td>See Bamboo licensing for details.</td>
</tr>
<tr>
<td>Does your system meet the minimum requirements?</td>
<td>See Supported platforms.</td>
</tr>
</tbody>
</table>

On this page: Before you begin

1. Enable remote agent support
2. Download and install the remote agent
3. Launch the remote agent
4. Configure the remote agent’s capabilities
Do you have a supported version of Java installed on the agent machine? See Supported platforms.

Are you upgrading your version of Bamboo? If yes, your remote-agents will be upgraded automatically along with Bamboo.

---

1. **Enable remote agent support**

   1. Click the ![ icon in the Bamboo header and choose Overview.](image)
   2. In the left-hand panel, under Build Resources, click Agents.
   3. Click either Enable Remote Agent Support or Disable Remote Agent Support.

   Read more about enabling and disabling remote agent support [here](#).

2. **Download and install the remote agent**

   1. Create a directory on the agent machine (e.g. bamboo-agent-home) to serve as the Bamboo agent home for the remote agent.
   2. Click the ![ icon in the Bamboo header and choose Overview.](image)
   3. In the left-hand panel, under Build Resource, click Agents in the left panel.
      The 'Agents' screen displays showing the lists of all local agents and all remote agents that currently exist on your Bamboo system.
   4. If not already enabled, click the Enable remote agent support link.
   5. Click Install Remote Agent. The 'Installing a remote agent' screen will display.
   6. Click DOWNLOAD Remote Agent JAR and save the JAR file to the directory on the agent machine that you created above.
   7. Copy the command under 'Running a Remote Agent' to the clipboard for use in Step 3 that follows.

3. **Launch the remote agent**

   Once installed, run the remote agent by executing the command line obtained above. This command will look something like this:

   ```bash
   java -jar atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
   http://bamboo-host-server:8085/bamboo/agentServer/
   ```

   Where X.X represents your Bamboo version number.

   If you are having issues launching the agent, then take a look at our troubleshooting guide.

See Configuring capabilities for more on defining capabilities.

### Bamboo remote agent installation guide v6.1

**Before you begin**

Before you begin installing remote agents, there are a few questions you need to answer:

- **Do you need to install a remote agent?**
  
  See Agents and capabilities to understand how remote agents interact with your Bamboo server.

- **Do you have sufficient agent licenses?**
  
  See Bamboo licensing for details.

- **Does your system meet the minimum requirements?**
  
  See Supported platforms.

- **Do you have a supported version of Java installed on the agent machine?**
  
  See Supported platforms.

- **Are you upgrading your version of Bamboo?**
  
  If yes, your remote-agents will be upgraded automatically along with Bamboo.

**Note that you can run multiple Bamboo agents on the same machine – you just need to provide a separate home directory for each agent installation.**

#### 1. Enable remote agent support

1. Click the ![icon](image) in the Bamboo header and choose **Overview**.
2. In the left-hand panel, under Build Resources, click **Agents**.
3. Click either Enable Remote Agent Support or Disable Remote Agent Support.

Read more about enabling and disabling remote agent support [here](#).

#### 2. Download and install the remote agent

1. Create a directory on the agent machine (e.g. `bamboo-agent-home`) to serve as the Bamboo agent home for the remote agent.
2. Click the ![icon](image) in the Bamboo header and choose **Overview**.
3. In the left-hand panel, under Build Resource, click **Agents** in the left panel.
   
   The 'Agents' screen displays showing the lists of all local agents and all remote agents that currently exist on your Bamboo system.
4. If not already enabled, click the Enable remote agent support link
5. Click Install Remote Agent. The 'Installing a remote agent' screen will display
6. Click **DOWNLOAD Remote Agent JAR** and save the JAR file to the directory on the agent machine that you created above.
7. Copy the command under 'Running a Remote Agent' to the clipboard for use in Step 3 that follows.

#### 3. Launch the remote agent

Once installed, run the remote agent by executing the command line obtained above. This command will look something like this:

```
java -jar atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
http://bamboo-host-server:8085/bamboo/agentServer/
```

On this page:

- Before you begin
  1. Enable remote agent support
  2. Download and install the remote agent
  3. Launch the remote agent
  4. Configure the remote agent's capabilities

Related pages:

- Configuring remote agent capabilities using `bamboo-capabilities.properties`

### Bamboo installation guide

1. Check the system requirements

#### Supported platforms

Please read the Supported platforms page before you install Bamboo. The Supported Platforms page lists the applications servers, databases, operating systems, web browsers and JDKs that we have tested Bamboo with and recommend.

Note that Bamboo ships with a built-in H2 database, which is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For the production environment, we recommend that you configure Bamboo to use an external database.

#### Hardware requirements

While some of our customers run Bamboo on SPARC-based hardware, Atlassian only officially supports Bamboo running on x86 hardware and 64-bit derivatives of x86 hardware.

#### Servlet container requirements

You will need a servlet container that supports the Servlet 2.4 specification. Most modern containers should comply with this.
2. Install and setup

Choose the relevant instructions for your operating system:

- Linux
- Mac
- Windows

3. Check for known issues and troubleshoot the Bamboo installation

If something is not working correctly after you have completed the steps above to install Bamboo, please check for known Bamboo issues and try troubleshooting your upgrade as described below:

- **Check for known issues.** Sometimes we find out about a problem with the latest version of Bamboo after we have released the software. In such cases we publish information about the known issues in the Bamboo Knowledge Base. Please check the known issues in the Bamboo Knowledge Base and follow the instructions to apply any necessary patches if necessary.

- **Did you encounter a problem during the Bamboo installation?** Please refer to the guide to troubleshooting upgrades in the Bamboo Knowledge Base.

- If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.

Running Bamboo as a service

You can configure Bamboo to start automatically on system startup, allowing it to recover automatically after a reboot.

Running Bamboo as a Windows Service

Running Bamboo as a Windows service as the local user

Running Bamboo as a Linux service

Running Bamboo as a Windows Service

Once you have installed Bamboo, you can choose to run Bamboo as service so that it starts up every time windows restarts.
Upgrading Bamboo server

- If you have just upgraded your Bamboo server, you must re-install the Bamboo service. You can do this by removing the service and installing it again.
- If you run Bamboo as a Windows service, make sure that the user has 'Full Control' access to the following directories:
  - In version 5.1 or later:
    - `<Bamboo_install_directory>/temp`
  - In version 5.15 or later:
    - `<Bamboo_install_directory>/temp`
    - `<Bamboo_home_directory>/xml-data/configuration/cipher`

Procedure:

1. Click on the Start menu in Windows,
2. Select Bamboo from the programs list,
3. Click on Install Service option to install Bamboo as a service in Windows.
4. Click Start Service to start the service.

Running Bamboo as a Windows Service v5.14

Once you have installed Bamboo, you can choose to run Bamboo as service so that it starts up every time windows restarts.

Upgrading Bamboo server

- If you have just upgraded your Bamboo server, you must re-install the Bamboo service. You can do this by removing the service and installing it again.
- If you run Bamboo as a Windows service, make sure that the user has 'Full Control' access to the following directories:
  - In version 5.1 or later:
    - `<Bamboo_install_directory>/temp`
  - In version 5.15 or later:
    - `<Bamboo_install_directory>/temp`
    - `<Bamboo_home_directory>/xml-data/configuration/cipher`

Procedure:

1. Click on the Start menu in Windows,
2. Select Bamboo from the programs list,
3. Click on Install Service option to install Bamboo as a service in Windows.
4. Click Start Service to start the service.
Running Bamboo as a Windows Service v5.15

Once you have installed Bamboo, you can choose to run Bamboo as service so that it starts up every time windows restarts.

**Upgrading Bamboo server**
- If you have just upgraded your Bamboo server, you must re-install the Bamboo service. You can do this by removing the service and installing it again.
- If you run Bamboo as a Windows service, make sure that the user has 'Full Control' access to the following directories:
  - In version 5.1 or later: `<Bamboo_install_directory>/temp`
  - In version 5.15 or later: `<Bamboo_install_directory>/temp`
  - `<Bamboo_home_directory>/xml-data/configuration/cipher`

Procedure:
1. Click on the **Start menu** in Windows.
2. Select **Bamboo** from the programs list.
3. Click on **Install Service** option to install Bamboo as a service in Windows.
4. Click **Start Service** to start the service.

Running Bamboo as a Windows Service v6.0

Once you have installed Bamboo, you can choose to run Bamboo as service so that it starts up every time windows restarts.

**Upgrading Bamboo server**
Running Bamboo as a Windows Service v6.1

Once you have installed Bamboo, you can choose to run Bamboo as service so that it starts up every time windows restarts.

### Upgrading Bamboo server

- If you have just upgraded your Bamboo server, you must re-install the Bamboo service. You can do this by removing the service and installing it again.
- If you run Bamboo as a Windows service, make sure that the user has 'Full Control' access to the following directories:
  - In version 5.1 or later:
    - `<Bamboo_install_directory>/temp`
  - In version 5.15 or later:
    - `<Bamboo_install_directory>/temp`
    - `<Bamboo_home_directory>/xml-data/configuration/cipher`

Procedure:

1. Click on the **Start menu** in Windows,
2. Select **Bamboo** from the programs list,
3. Click on **Install Service** option to install Bamboo as a service in Windows.
4. Click **Start Service** to start the service.
Running Bamboo as a Windows service as the local user

1. Install Bamboo Application Server
   
   1. Download Bamboo and run the Setup Wizard.
   2. Install Bamboo as Windows service, as described in Running Bamboo as a Windows service.

2. Edit the Bamboo service to run as the "local user"
   
   1. Go to Start -> Run and enter 'services.msc'.
   2. The 'Services' window will display (see screenshot below). Double-click the 'Bamboo build server' row.

   3. The 'Bamboo build server Properties' window will display (see screenshot above). Select the 'This account' option, provide a local admin account credentials, and click the 'OK' button to apply your changes.

3. Give the local user access to "logon as a service"
   
   1. Go to Start -> Run and enter 'secpol.msc'
   2. The 'Local Security Settings' window will display. Expand the 'Local Policies' tree and click 'User Rights Assignment'.
3. Scroll down and find the 'Logon As a Service' Policy (see screenshot below). Double-click the 'Log on as a service' policy.

4. The properties window for the 'Log on as a service' policy will display (see screenshot below). Click the 'Add User or Group' button.

5. The 'Select Users or Groups' window will display (see screenshot above). Enter your local user and click 'OK' to allow your user to
Bamboo will now start as service, under the local user.

**Running Bamboo as a Linux service**

Linux system administration is outside the scope of Atlassian support. This page is provided for your information only.

On Linux/Solaris, the best practice is to install, configure and run each service (including Bamboo) as a dedicated user with only the permissions they require.

To install, configure and get Bamboo to start automatically on Linux/Solaris:

1. Create a bamboo user account which will be used to run Bamboo. For example, enter the following at a Linux console:

   ```bash
   sudo useradd --create-home -c "Bamboo role account" bamboo
   ```

2. Create a directory into which Bamboo will be installed. For example:

   ```bash
   sudo mkdir -p /opt/atlassian/bamboo
   sudo chown bamboo: /opt/atlassian/bamboo
   ```

3. Log in as the bamboo user to install Bamboo:

   ```bash
   sudo su - bamboo
   ```

4. You need to extract Bamboo:

   ```bash
   cd /opt/atlassian/bamboo
   tar zxvf /tmp/atlassian-bamboo-X.Y.tar.gz
   ln -s atlassian-bamboo-X.Y/ current
   ```

5. Edit `current/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties` and set `bamboo.home=/var/atlassian/application-data/bamboo` (or any other directory of your choice, but not the same as Bamboo's installation directory).

6. Then back as root, create the file `/etc/init.d/bamboo` (code shown below), which will be responsible for starting up bamboo after a reboot (or when manually invoked).
#!/bin/sh
set -e
### BEGIN INIT INFO
# Provides: bamboo
# Required-Start: $local_fs $remote_fs $network $time
# Required-Stop: $local_fs $remote_fs $network $time
# Should-Start: $syslog
# Should-Stop: $syslog
# Default-Start: 2 3 4 5
# Default-Stop: 0 1 6
# Short-Description: Atlassian Bamboo Server
### END INIT INFO
# INIT Script
######################################
# Define some variables
# Name of app ( bamboo, Confluence, etc )
APP=bamboo
# Name of the user to run as
USER=bamboo
# Location of application's bin directory
BASE=/opt/atlassian/bamboo/current

case "$1" in
  # Start command
  start)
    echo "Starting $APP"
    /bin/su - $USER -c "export BAMBOO_HOME=${BAMBOO_HOME}; $BASE/bin/startup.sh &> /dev/null"
    ;;
  # Stop command
  stop)
    echo "Stopping $APP"
    /bin/su - $USER -c "$BASE/bin/shutdown.sh &> /dev/null"
    echo "$APP stopped successfully"
    ;;
  # Restart command
  restart)
    $0 stop
    sleep 5
    $0 start
    ;;
  *)
    echo "Usage: /etc/init.d/$APP {start|restart|stop}"
    exit 1
    ;;
esac
exit 0

7. Make the init script executable:

    chmod a+x /etc/init.d/bamboo
8. Place symlinks in the run-level directories to start and stop this script automatically.
   
   a. For Debian-based systems:
   
   ```bash
   update-rc.d bamboo defaults
   ```
   
   The following commands will be executed to place symlinks in the run-level directories:
   
   ```bash
   Adding system startup for /etc/init.d/bamboo ...
   /etc/rc0.d/K20bamboo -> ../init.d/bamboo
   /etc/rc1.d/K20bamboo -> ../init.d/bamboo
   /etc/rc2.d/S20bamboo -> ../init.d/bamboo
   /etc/rc3.d/S20bamboo -> ../init.d/bamboo
   /etc/rc4.d/S20bamboo -> ../init.d/bamboo
   /etc/rc5.d/S20bamboo -> ../init.d/bamboo
   ```

   b. For RedHat-based systems:

   ```bash
   the init.d script contains chkconfig settings
   ```

   ```bash
   sudo /sbin/chkconfig --add bamboo
   ```

9. Ensure the script is executed in the correct order, in particular after the database startup script.

   Note: If starting your new `bamboo` service fails immediately with an error, it may be that your `/etc/init.d/bamboo` script has had carriage return characters introduced into it. You can confirm this by running:

   ```bash
   cat -v /etc/init.d/bamboo
   ```

   If there are carriage return characters in your `/etc/init.d/bamboo` script, they will appear as `^M` in the output:

   ```bash
   #!/bin/sh
   set -e
   ### BEGIN INIT INFO
   # Provides: bamboo
   # Required-Start: $local_fs $remote_fs $network $time
   # Required-Stop: $local_fs $remote_fs $network $time
   # Should-Start: $syslog
   # Should-Stop: $syslog
   ```

   You can remove carriage return characters from `/etc/init.d/bamboo` with the following command:

   ```bash
   sed -i -e 's/\r//g' /etc/init.d/bamboo
   ```

   Retry starting the service after making this change.

---

**Running Bamboo as a Linux service v5.14**

---

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
On Linux/Solaris, the best practice is to install, configure and run each service (including Bamboo) as a dedicated user with only the permissions they require.

To install, configure and get Bamboo to start automatically on Linux/Solaris:

1. Create a bamboo user account which will be used to run Bamboo. For example, enter the following at a Linux console:

   ```
sudo useradd --create-home -c "Bamboo role account" bamboo
   ```

2. Create a directory into which Bamboo will be installed. For example:

   ```
sudo mkdir -p /opt/atlassian/bamboo
   sudo chown bamboo: /opt/atlassian/bamboo
   ```

3. Log in as the bamboo user to install Bamboo:

   ```
sudo su - bamboo
   ```

4. You need to extract Bamboo:

   ```
cd /opt/atlassian/bamboo
   tar zxvf /tmp/atlassian-bamboo-X.Y.tar.gz
   ln -s atlassian-bamboo-X.Y/ current
   ```

5. Edit `current/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties` and set `bamboo.home=/var/atlassian/application-data/bamboo` (or any other directory of your choice, but not the same as Bamboo’s installation directory).

6. Then back as root, create the file `/etc/init.d/bamboo (code shown below), which will be responsible for starting up bamboo after a reboot (or when manually invoked).
```bash
#!/bin/sh
set -e
### BEGIN INIT INFO
# Provides: bamboo
# Required-Start: $local_fs $remote_fs $network $time
# Required-Stop: $local_fs $remote_fs $network $time
# Should-Start: $syslog
# Should-Stop: $syslog
# Default-Start: 2 3 4 5
# Default-Stop: 0 1 6
# Short-Description: Atlassian Bamboo Server
### END INIT INFO
# INIT Script
######################################
# Define some variables
# Name of app ( bamboo, Confluence, etc )
APP=bamboo
# Name of the user to run as
USER=bamboo
# Location of application's bin directory
BASE=/opt/atlassian/bamboo/current

case "$1" in
  # Start command
  start)
    echo "Starting $APP"
    /bin/su - $USER -c "export BAMBOO_HOME=${BAMBOO_HOME};
    $BASE/bin/startup.sh &> /dev/null"
    ;;
  # Stop command
  stop)
    echo "Stopping $APP"
    /bin/su - $USER -c "$BASE/bin/shutdown.sh &> /dev/null"
    echo "$APP stopped successfully"
    ;;
  # Restart command
  restart)
    $0 stop
    sleep 5
    $0 start
    ;;
  *)
    echo "Usage: /etc/init.d/$APP {start|restart|stop}"
    exit 1
    ;;
esac

exit 0
```

7. Make the init script executable:

```bash
chmod a+x /etc/init.d/bamboo
```
8. Place symlinks in the run-level directories to start and stop this script automatically.

   a. For Debian-based systems:

```
update-rc.d bamboo defaults
```

The following commands will be executed to place symlinks in the run-level directories:

```
Adding system startup for /etc/init.d/bamboo ...
/etc/rc0.d/K20bamboo -> ../init.d/bamboo
/etc/rc1.d/K20bamboo -> ../init.d/bamboo
/etc/rc6.d/K20bamboo -> ../init.d/bamboo
/etc/rc2.d/S20bamboo -> ../init.d/bamboo
/etc/rc3.d/S20bamboo -> ../init.d/bamboo
/etc/rc4.d/S20bamboo -> ../init.d/bamboo
/etc/rc5.d/S20bamboo -> ../init.d/bamboo
```

b. For RedHat-based systems:

```
the init.d script contains chkconfig settings
```

```
sudo /sbin/chkconfig --add bamboo
```

9. Ensure the script is executed in the correct order, in particular after the database startup script.

Note: If starting your new bamboo service fails immediately with an error, it may be that your /etc/init.d/bamboo script has had carriage return characters introduced into it. You can confirm this by running:

```
cat -v /etc/init.d/bamboo
```

If there are carriage return characters in your /etc/init.d/bamboo script, they will appear as ^M in the output:

```
#!/bin/sh^M
set -e^M
### BEGIN INIT INFO^M
# Provides: bamboo^M
# Required-Start: $local_fs $remote_fs $network $time^M
# Required-Stop: $local_fs $remote_fs $network $time^M
# Should-Start: $syslog^M
# Should-Stop: $syslog^M
```

You can remove carriage return characters from /etc/init.d/bamboo with the following command:

```
sed -i -e 's/\r//g' /etc/init.d/bamboo
```

Retry starting the service after making this change.

. Running Bamboo as a Linux service v6.2
On Linux/Solaris, the best practice is to install, configure and run each service (including Bamboo) as a dedicated user with only the permissions they require.

To install, configure and get Bamboo to start automatically on Linux/Solaris:

1. Create a bamboo user account which will be used to run Bamboo. For example, enter the following at a Linux console:

   ```
sudo useradd --create-home -c "Bamboo role account" bamboo
   ```

2. Create a directory into which Bamboo will be installed. For example:

   ```
sudo mkdir -p /opt/atlassian/bamboo
sudo chown bamboo: /opt/atlassian/bamboo
   ```

3. Log in as the bamboo user to install Bamboo:

   ```
sudo su - bamboo
   ```

4. You need to extract Bamboo:

   ```
   cd /opt/atlassian/bamboo
   tar zxvf /tmp/atlassian-bamboo-X.Y.tar.gz
   ln -s atlassian-bamboo-X.Y/ current
   ```

5. Edit `current/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties` and set `bamboo.home=/var/atlassian/application-data/bamboo` (or any other directory of your choice, but not the same as Bamboo’s installation directory)

6. Proceed with the service configuration. There are two options included below for creating the service configuration, which one you will use will depend on your Linux distribution:

   <Systemd Service Configuration>

   ```
   Suitable for modern distributions such as:
   · Ubuntu 15
   · CentOS 7
   · RHEL 7
   For anything older see the SysV Init Script section below
   ```

   1. Create a `bamboo.service` file in your `/etc/systemd/system` directory
[Unit]
Description=Atlassian Bamboo
After=syslog.target network.target

[Service]
Type=forking
User=<bamboo-user>
ExecStart=<bamboo-install>/bin/start-bamboo.sh
ExecStop=<bamboo-install>/bin/stop-bamboo.sh
SuccessExitStatus=143

[Install]
WantedBy=multi-user.target

The values for <bamboo-user> and <bamboo-install> should be replaced with your Bamboo user and the path to your Bamboo Install directory, respectively.

2. Enable the service to start at boot time by running the following in a terminal:

    systemctl enable bamboo.service

3. Stop Bamboo using the provided Bamboo stop script (<bamboo-install>/bin/stop-bamboo.sh) and restart your system to check that Bamboo starts as expected.

4. Use the following commands to manage the service:

   **Disable the service:**

    systemctl disable bamboo.service

   **Check that the service is set to start at boot time:**

    if [ -f /etc/systemd/system/*.wants/bamboo.service ]; then echo "On"; else echo "Off"; fi

   **Manually start and stop the service:**

    systemctl start bamboo
    systemctl stop bamboo

   **Check the status of Bamboo:**

    systemctl status bamboo

SysV Init Script

1. As root, create the file /etc/init.d/bamboo (code shown below), which will be responsible for starting up bamboo after a reboot (or when manually invoked).
#!/bin/sh
set -e
### BEGIN INIT INFO
# Provides: bamboo
# Required-Start: $local_fs $remote_fs $network $time
# Required-Stop: $local_fs $remote_fs $network $time
# Should-Start: $syslog
# Should-Stop: $syslog
# Default-Start: 2 3 4 5
# Default-Stop: 0 1 6
# Short-Description: Atlassian Bamboo Server
### END INIT INFO
# INIT Script

# Define some variables
# Name of app ( bamboo, Confluence, etc )
APP=bamboo
# Name of the user to run as
USER=bamboo
# Location of application's bin directory
BASE=/opt/atlassian/bamboo/current

case "$1" in
  # Start command
  start)
    echo "Starting $APP"
    /bin/su - $USER -c "export BAMBOO_HOME=${BAMBOO_HOME};
    $BASE/bin/startup.sh &> /dev/null"
    ;;

  # Stop command
  stop)
    echo "Stopping $APP"
    /bin/su - $USER -c "$BASE/bin/shutdown.sh &> /dev/null"
    echo "$APP stopped successfully"
    ;;

  # Restart command
  restart)
    $0 stop
    sleep 5
    $0 start
    ;;
  *)
    echo "Usage: /etc/init.d/$APP {start|restart|stop}"
    exit 1
    ;;
esac
exit 0

2. Make the init script executable:

    chmod a+x /etc/init.d/bamboo
3. Place symlinks in the run-level directories to start and stop this script automatically.
   a. For Debian-based systems:

   ```bash
   update-rc.d bamboo defaults
   ```
   
   The following commands will be executed to place symlinks in the run-level directories:

   ```bash
   Adding system startup for /etc/init.d/bamboo ...
   /etc/rc0.d/K20bamboo -> ../init.d/bamboo
   /etc/rc1.d/K20bamboo -> ../init.d/bamboo
   /etc/rc6.d/K20bamboo -> ../init.d/bamboo
   /etc/rc2.d/S20bamboo -> ../init.d/bamboo
   /etc/rc3.d/S20bamboo -> ../init.d/bamboo
   /etc/rc4.d/S20bamboo -> ../init.d/bamboo
   /etc/rc5.d/S20bamboo -> ../init.d/bamboo
   ```

   b. For RedHat-based systems:

   ```bash
   sudo /sbin/chkconfig --add bamboo
   ```
   
   Ensure the script is executed in the correct order, in particular after the database startup script.

4. Ensure the script is executed in the correct order, in particular after the database startup script.

   Note: If starting your new `bamboo` service fails immediately with an error, it may be that your `/etc/init.d/bamboo` script has had carriage return characters introduced into it. You can confirm this by running:

   ```bash
   cat -v /etc/init.d/bamboo
   ```
   
   If there are carriage return characters in your `/etc/init.d/bamboo` script, they will appear as `^M` in the output:

   ```bash
   #!/bin/sh
   set -e
   ### BEGIN INIT INFO
   # Provides: bamboo
   # Required-Start: $local_fs $remote_fs $network $time
   # Required-Stop: $local_fs $remote_fs $network $time
   # Should-Start: $syslog
   # Should-Stop: $syslog
   ```
   
   You can remove carriage return characters from `/etc/init.d/bamboo` with the following command:

   ```bash
   sed -i -e 's/^/\//' /etc/init.d/bamboo
   ```
   
   Retry starting the service after making this change.

---

_Running Bamboo as a Linux service v6.6_
On Linux/Solaris, the best practice is to install, configure and run each service (including Bamboo) as a dedicated user with only the permissions they require.

To install, configure and get Bamboo to start automatically on Linux/Solaris:

1. Create a bamboo user account which will be used to run Bamboo. For example, enter the following at a Linux console:

   ```
   sudo useradd --create-home -c "Bamboo role account" bamboo
   ```

2. Create a directory into which Bamboo will be installed. For example:

   ```
   sudo mkdir -p /opt/atlassian/bamboo
   sudo chown bamboo: /opt/atlassian/bamboo
   ```

3. Log in as the bamboo user to install Bamboo:

   ```
   sudo su - bamboo
   ```

4. You need to extract Bamboo:

   ```
   cd /opt/atlassian/bamboo
   tar zxvf /tmp/atlassian-bamboo-X.Y.tar.gz
   ln -s atlassian-bamboo-X.Y/ current
   ```

5. Edit `current/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties` and set `bamboo.home=/var/atlassian/application-data/bamboo` (or any other directory of your choice, but not the same as Bamboo's installation directory)

6. Proceed with the service configuration. There are two options included below for creating the service configuration, which one you will use will depend on your Linux distribution:

   **Systemd Service Configuration**

   Suitable for modern distributions such as:

   - Ubuntu 15
   - CentOS 7
   - RHEL 7

   For anything older see the SysV Init Script section below.

   ```
   Systemd will ignore environment variable definitions placed in /etc/environment as well as other traditional environment variable definitions from Sys-V init. If one needs to define environment variables when running Bamboo as a systemd unit then the variable definitions need to be placed in the unit file.
   ```

   ```
   1. Create a `bamboo.service` file in your `/etc/systemd/system` directory
   ```
[Unit]
Description=Atlassian Bamboo
After=syslog.target network.target

[Service]
Type=forking
User=<bamboo-user>
ExecStart=<bamboo-install>/bin/start-bamboo.sh
ExecStop=<bamboo-install>/bin/stop-bamboo.sh
SuccessExitStatus=143

[Install]
WantedBy=multi-user.target

The values for <bamboo-user> and <bamboo-install> should be replaced with your Bamboo user and the path to your Bamboo Install directory, respectively.

2. Enable the service to start at boot time by running the following in a terminal:

   systemctl enable bamboo.service

3. Stop Bamboo using the provided Bamboo stop script (<bamboo-install>/bin/stop-bamboo.sh) and restart your system to check that Bamboo starts as expected

4. Use the following commands to manage the service:

Disable the service:

   systemctl disable bamboo.service

Check that the service is set to start at boot time:

   if [ -f /etc/systemd/system/*.wants/bamboo.service ]; then echo "On"; else echo "Off"; fi

Manually start and stop the service:

   systemctl start bamboo
   systemctl stop bamboo

Check the status of Bamboo:

   systemctl status bamboo

SysV Init Script
1. As root, create the file /etc/init.d/bamboo (code shown below), which will be responsible for starting up bamboo after a reboot (or when manually invoked).
#!/bin/sh
set -e
### BEGIN INIT INFO

   # Required-Stop: $local_fs $remote_fs $network $time
   # Should-Start: $syslog
   # Should-Stop: $syslog
   ```
   
   You can remove carriage return characters from `/etc/init.d/bamboo` with the following command:
   
   ```sh
   sed -i -e 's/\r//g' /etc/init.d/bamboo
   ```
   
   Retry starting the service after making this change.

---

**Running Bamboo as a Linux service v6.7**

Created by Atlassian in 2018. Licensed under a [Creative Commons Attribution 2.5 Australia License](http://creativecommons.org/licenses/by/2.5/au/).
On Linux/Solaris, the best practice is to install, configure and run each service (including Bamboo) as a dedicated user with only the permissions they require.

To install, configure and get Bamboo to start automatically on Linux/Solaris:

1. Create a bamboo user account which will be used to run Bamboo. For example, enter the following at a Linux console:

```
sudo useradd --create-home -c "Bamboo role account" bamboo
```

2. Create a directory into which Bamboo will be installed. For example:

```
sudo mkdir -p /opt/atlassian/bamboo
sudo chown bamboo: /opt/atlassian/bamboo
```

3. Log in as the bamboo user to install Bamboo:

```
sudo su - bamboo
```

4. You need to extract Bamboo:

```
cd /opt/atlassian/bamboo
tar zxf /tmp/atlassian-bamboo-X.Y.tar.gz
ln -s atlassian-bamboo-X.Y/ current
```

5. Edit current/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties and set bamboo.home=/var/atlassian/application-data/bamboo (or any other directory of your choice, but not the same as Bamboo's installation directory)

6. Proceed with the service configuration. There are two options included below for creating the service configuration, which one you will use will depend on your Linux distribution:

**Systemd Service Configuration**

Suitable for modern distributions such as:

- Ubuntu 15
- CentOS 7
- RHEL 7

For anything older see the SysV Init Script section below.

Systemd will ignore environment variable definitions placed in /etc/environment as well as other traditional environment variable definitions from Sys-V init. If one needs to define environment variables when running Bamboo as a systemd unit then the variable definitions need to be placed in the unit file.

1. Create a bamboo.service file in your /etc/systemd/system directory
[Unit]
Description=Atlassian Bamboo
After=syslog.target network.target

[Service]
Type=forking
User=<bamboo-user>
ExecStart=<bamboo-install>/bin/start-bamboo.sh
ExecStop=<bamboo-install>/bin/stop-bamboo.sh
SuccessExitStatus=143

[Install]
WantedBy=multi-user.target

The values for <bamboo-user> and <bamboo-install> should be replaced with your Bamboo user and the path to your Bamboo Install directory, respectively.

2. Enable the service to start at boot time by running the following in a terminal:

```bash
systemctl enable bamboo.service
```

3. Stop Bamboo using the provided Bamboo stop script (<bamboo-install>/bin/stop-bamboo.sh) and restart your system to check that Bamboo starts as expected.

4. Use the following commands to manage the service:

   **Disable the service:**
   ```bash
   systemctl disable bamboo.service
   ```

   **Check that the service is set to start at boot time:**
   ```bash
   if [ -f /etc/systemd/system/*.wants/bamboo.service ]; then echo "On"; else echo "Off"; fi
   ```

   **Manually start and stop the service:**
   ```bash
   systemctl start bamboo
   systemctl stop bamboo
   ```

   **Check the status of Bamboo:**
   ```bash
   systemctl status bamboo
   ```

**SysV Init Script**

1. As root, create the file `/etc/init.d/bamboo` (code shown below), which will be responsible for starting up bamboo after a reboot (or when manually invoked).

   ```bash
   [Unit]
   Description=Atlassian Bamboo
   After=syslog.target network.target

   [Service]
   Type=forking
   User=<bamboo-user>
   ExecStart=<bamboo-install>/bin/start-bamboo.sh
   ExecStop=<bamboo-install>/bin/stop-bamboo.sh
   SuccessExitStatus=143

   [Install]
   WantedBy=multi-user.target
   ```
#!/bin/sh
set -e
### BEGIN INIT INFO

  chmod a+x /etc/init.d/bamboo
3. Place symlinks in the run-level directories to start and stop this script automatically.
   
   a. For Debian-based systems:

   ```sh
   update-rc.d bamboo defaults
   ```

   The following commands will be executed to place symlinks in the run-level directories:

   ```
   Adding system startup for /etc/init.d/bamboo ...
   /etc/rc0.d/K20.bamboo -> ../init.d/bamboo
   /etc/rc1.d/K20.bamboo -> ../init.d/bamboo
   /etc/rc2.d/S20.bamboo -> ../init.d/bamboo
   /etc/rc3.d/S20.bamboo -> ../init.d/bamboo
   /etc/rc4.d/S20.bamboo -> ../init.d/bamboo
   /etc/rc5.d/S20.bamboo -> ../init.d/bamboo
   ```

   b. For RedHat-based systems:

   ```sh
   sudo /sbin/chkconfig --add bamboo
   ```

   The init.d script contains chkconfig settings

4. Ensure the script is executed in the correct order, in particular after the database startup script.

   **Note:** If starting your new `bamboo` service fails immediately with an error, it may be that your `/etc/init.d/bamboo` script has had carriage return characters introduced into it. You can confirm this by running:

   ```sh
   cat -v /etc/init.d/bamboo
   ```

   If there are carriage return characters in your `/etc/init.d/bamboo` script, they will appear as `^M` in the output:

   ```
   #!/bin/sh
   set -e
   ### BEGIN INIT INFO
   # Provides: bamboo
   # Required-Start: $local_fs $remote_fs $network $time
   # Required-Stop: $local_fs $remote_fs $network $time
   # Should-Start: $syslog
   # Should-Stop: $syslog
   ```

   You can remove carriage return characters from `/etc/init.d/bamboo` with the following command:

   ```sh
   sed -i -e 's/\r//g' /etc/init.d/bamboo
   ```

   Retry starting the service after making this change.

---

**Bamboo upgrade guide**

You can upgrade Bamboo by installing a new version of Bamboo and setting it up with the configuration of the original Bamboo.
Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page. Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>1. Clone your Bamboo instance into the new location. 2. Perform the upgrade steps on the cloned Bamboo instance as described on this page. The cloned instance on the new server is referred to as original Bamboo instance.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.

We recommend that you test the Bamboo upgrade on a QA server before deploying to production.

If you are a Bamboo plugin developer, see our Bamboo API Changes by Version guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

Before you begin

Determine your upgrade path

- When upgrading from very old versions of Bamboo you must follow this upgrade path:
  - OLDER VERSIONS
  - 2.0.6
  - 2.6.3
  - 2.7.4
  - 5.0–5.7

- When upgrading from earlier than Bamboo 5.0, you must upgrade to any of Bamboo 5.0–5.14 before upgrading to Bamboo latest version:
  - 4.0–4.4
  - 5.0–5.14
  - LATEST

- When upgrading from Bamboo 5.0 and later, you can upgrade directly to the latest version of Bamboo:

  - 5.0 +
  - LATEST

You do not need to downgrade before upgrading.

Before you begin

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

The installation path is referred to as `<bamboo-install>` and points to the directory into which you extracted the Bamboo package. It is different from `<bamboo-home>`, which points to the directory where Bamboo data is stored.
1. Export and back up the existing Bamboo data

**Export the Bamboo database**

There are two database backup scenarios, depending on whether you are using an embedded or external database.

<table>
<thead>
<tr>
<th>Embedded HSQL database</th>
<th>External database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an export .zip file for the original Bamboo instance. For more information, see Exporting data for backup.</td>
<td>Use native database tools to create a backup. For more information about external databases, see Connecting Bamboo to an external database.</td>
</tr>
<tr>
<td>The export may take a long time to complete and may require a large amount of disk space, depending on the number of builds and tests in your system.</td>
<td></td>
</tr>
</tbody>
</table>

**Stop Bamboo**

Stop the original Bamboo instance.

If you have Bamboo running as a Windows service, uninstall the service by using the UninstallService.bat executable that came with your Bamboo instance.

**Back up the Bamboo configuration**

When the original Bamboo instance is shut down, back up your `<bamboo-home>` directory, which contains the `builds` and `configuration` directories. You can compress it into a .zip file.

Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path:

![Bamboo paths]

For more information about these directories, see Important Directories and Files.

2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a `<bamboo-install>` directory that is different from the `<bamboo-install>` directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- Make sure that the original Bamboo instance is not running before you start the new installation.
- To prevent data loss during updates or reinstallation, the `<bamboo-home>` directory must be different from the `<Bamboo-install>` directory.
The guidelines for the new Bamboo instance installation are the following:

**Mac OS X**
- The Mac installer deletes the previous version of Bamboo.
- Follow the Mac OS X install instructions.

**Linux**
- Delete your old `<Bamboo-install>` directory to remove any legacy files.
- Follow the Linux install instructions.

**Windows**
- The Windows installer deletes the previous version of Bamboo.
- Follow the Windows install instructions.
- Configure Bamboo to run as a service on Windows, using the `service.bat` executable.

### 3. Configure the new Bamboo instance

#### Set the home directory for the new Bamboo instance

Set the `<home-directory>` to use the `<home-directory>` of the original Bamboo instance:

1. Go to the new Bamboo instance `<bamboo-install>` directory. It is the directory where you installed Bamboo.
2. Open `atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`

For Bamboo versions prior to 5.1, the file path is: `<bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties`

3. Set the `bamboo.home` variable to use the `<bamboo-home>` path of the original Bamboo instance.

**Reconnect external user directories (optional)**

If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance.

For more information, see [Integrating Crowd with Bamboo](#) and [Integrating Bamboo with LDAP](#).

**Update any installed add-ons**

If you installed any add-ons in addition to the pre-installed system add-ons:

- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

**Automatic update of remote agents**

For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.

For more information, see [Bamboo remote agent installation guide](#).

**Configure the context path**

If you had a context path configured for the original Bamboo instance ([http://hostname[:port]/context_path](http://hostname[:port]/context_path)), you have to configure it for the new Bamboo instance. For more information, see [Changing Bamboo’s root context path](#).

**Check database access permission**

Before you start the new Bamboo instance, make sure that it has the `write` access to the database, which is required to complete the upgrade tasks.

### 4. Start Bamboo

---
Start Bamboo

Once you have installed Bamboo and set the `bamboo.home` property, start the new Bamboo instance. The upgrade runs automatically.

You can check whether the upgrade was successful in the `atlassian-bamboo.log` file.

Upgrading Bamboo may require reindexing.

Depending on the number of existing builds and tests, the reindexing process may take a significant amount of time, during which Bamboo will not be available.

Version-specific upgrade notes

The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

- Determine your upgrade path
- Before you begin
- Upgrading to Bamboo 6.3
- Upgrading to Bamboo 6.2
- Upgrading to Bamboo 6.1
- Upgrading to Bamboo 6.0
- Upgrading to Bamboo 5.15
- Upgrading to Bamboo 5.14
- Upgrading to Bamboo 5.13
- Upgrading to Bamboo 5.12
- Upgrading to Bamboo 5.11
- Upgrading to Bamboo 5.10
- Upgrading to Bamboo 5.9
- Upgrading to Bamboo 5.8
- Upgrading to Bamboo 5.7
- Upgrading to Bamboo 5.6
- Upgrading to Bamboo 5.5
- Upgrading to Bamboo 5.4

Upgrading to Bamboo 6.3

See also:

- the general update steps section above.
- Bamboo 6.3 Release Notes
- the Bamboo Supported platforms page.

Change to the built-in database

Starting with Bamboo 6.3, the built-in HSQL database is replaced by H2. If you store any data in HSQL and want to keep it after the upgrade, you must export the data to XML and import back after you've installed the new version of Bamboo. See:

- Exporting data for backup
- Importing data from backup

The H2 database is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.

Upgrading to Bamboo 6.2

See also:

- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

Upgrading to Bamboo 6.1

See also:

- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.
You might also want to check our Bamboo Specs reference documentation.

Upgrading to Bamboo 6.0

**Microsoft JDBC driver**

With Bamboo 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver.

If database settings are configured directory in Bamboo, then during 6.0 upgrade it will attempt to update driver settings. In case of customized settings Bamboo instance administrator will be required to manually convert the settings.

If database settings are configured in the container (Tomcat) and Bamboo uses datasource, automatic upgrade will not be possible and instance administration will be required to manually convert the settings.

To learn more about this change, see [here](#).

**New library for setting up a JNDI resource for SMTP**

Bamboo 6.0 is shipped with the `javax.mail-api-1.5.6.jar` library. This library needs to copied over to your `<Bamboo-install>/lib` folder when setting up a JNDI resource for SMTP. For more information, see [here](#).

**Changes to Git support**

Starting from version 6.0, Bamboo changes support for Git to version 1.8.1.5 or later.

Upgrading to Bamboo 5.15

Bamboo 5.15 contains upgrade tasks that can take extra time when moving from earlier versions of Bamboo. Keep this in mind when planning your upgrade outages.

Upgrading to Bamboo 5.14

**New API for VCS repositories**

We've rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

**Action required**

Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you're using any plugins that aren't officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian Marketplace).

Plugins that are particularly prone to incompatibilities and require special attention are those that deal with:

- automatic plan creation and management
- automatic plan branch creation and management
- repository configuration management

We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.

For details about the API changes, see our developer documentation.

**Changes in requirements for table names of the external databases**

With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:

- Upgrading to Bamboo 5.13 below
- MySQL
- Bamboo 5.13 Release Notes

**See also**

- the general update steps section above.
- Bamboo 5.14 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.
Upgrading to Bamboo 5.13

Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft SQL Server</td>
<td>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see Microsoft SQL Server.</td>
</tr>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to Connecting Bamboo to an external database. For MySQL specifically, this might affect all databases in the instance, see MySQL documentation.</td>
</tr>
</tbody>
</table>

If the check fails

If the check fails and you can't correct your database configuration immediately, you can roll back to the previous installed version of Bamboo without changing anything in your database or home directory configuration.

See also:
- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.12

See:
- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.11

See:
- the general update steps section above.
- Bamboo 5.11 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.10

See:
- the general update steps section above.
- Bamboo 5.10 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.9

See also:
- the general update steps section above.
• the Bamboo 5.9 Release Notes.
• the Bamboo Supported platforms page.

Changes to Clover Plugin integration

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before). Automatic Clover integration will not happen when your Maven task contains the install or deploy commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the install or deploy Maven commands. If they do: either disable automatic Clover integration for those jobs, or change the phase to the verify command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover’s coverage reports.

Upgrading to Bamboo 5.8

See also:
• the general update steps section above.
• the Bamboo 5.8 Release Notes.
• the Bamboo Supported platforms page.

If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

Hibernate dialect update

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the bamboo.cfg.xml file. The new dialects are:

- org.hibernate.dialect.PostgreSQLDialect
- org.hibernate.dialect.HSQLDialect
- org.hibernate.dialect.Oracle10gDialect
- org.hibernate.dialect.MySQL5Dialect
- com.atlassian.bamboo.hibernate.SQLServerIntlDialect

Upgrading to Bamboo 5.7

See also:
• the general update steps section above.
• the Bamboo 5.7 Release Notes.
• the Bamboo Supported platforms page.

Global deployment expiry

If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7. Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be removed. Most likely this is what you want but it’s important to be aware of this change. Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release.

Read more about global expiry in Bamboo 5.7.

Upgrading to Bamboo 5.6

See also:
• the general update steps section above.
• the Bamboo 5.6 Release Notes.
• the Bamboo Supported platforms page.

Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated

Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on Bitbucket Server.
Update time

When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the VARIABLE_CONTEXT table. For a more precise calculation, assume that 10 minutes are needed to process 15 million records in that table.

Installer package on MAC OS X can not be opened due to code signing requirements

Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.5.

Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see [BAM-11742](https://confluence.atlassian.com/browse/BAM-11742) - Installer package is "damaged and cannot be reopened" on Mac OS X for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available [here](https://confluence.atlassian.com/browse/BAM-11742).

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

Upgrading to Bamboo 5.5

- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket servers. If you have previously [integrated Bamboo with Bitbucket Server](https://confluence.atlassian.com/doc/integrating-bitbucket-server-and-bamboo-1185057493.html), you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but OAuth is a better as it is an impersonating authentication type. For more information, see [Configuring authentication for an application link](https://confluence.atlassian.com/display/BC/Bamboo+integration+with+Bitbucket+Server+for+problem+owners).
- Git will use `--ancestry-path` when trying to extract changeset due to [BAM-13760](https://confluence.atlassian.com/browse/BAM-13760) - Too many notifications for release -> feature merge in Git plan branches. Since that command is available for Git 1.7.2 and above (see [Release Notes](https://confluence.atlassian.com/display/BC/Bamboo+integration+with+Bitbucket+Server+for+problem+owners)), please update your native Git, if you have Git 1.7.1 installed (especially those who use RHEL 6 or CentOS).

See also:

- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

Installer package on MAC OS X can not be opened due to code signing requirements

Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.5.

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see [BAM-11742](https://confluence.atlassian.com/browse/BAM-11742) - Installer package is "damaged and cannot be reopened" on Mac OS X for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available [here](https://confluence.atlassian.com/browse/BAM-11742).

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

Upgrading to Bamboo 5.4

Note that Bamboo will run a full reindex after updating.

See also:

- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

Installer package on MAC OS X can not be opened due to code signing requirements
Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a workaround to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see -

BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X [RESOLVED] for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around solution available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

Troubleshooting

If you followed the documentation and you still have problems with the upgrade process:

- Check the How to Upgrade/Migrate Bamboo article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- You can also create a support ticket. To help us address the issue, attach the atlassian-bamboo.log file to the ticket.

Bamboo upgrade guide v5.14

You can upgrade Bamboo by installing a new version of Bamboo and setting it up with the configuration of the original Bamboo instance.

On this page

- Overview
- Recommended upgrade path
- 1. Export and back up the existing Bamboo data
- 2. Download and install a new Bamboo instance
- 3. Configure the new Bamboo instance
- 4. Start Bamboo
- Version-specific upgrade notes
- Troubleshooting

Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page. Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>1. Clone your Bamboo instance into the new location. 2. Perform the upgrade steps on the cloned Bamboo instance as described on this page. The cloned instance on the new server is referred to as original Bamboo instance.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.

We recommend that you test the Bamboo upgrade on a QA server before deploying to production.

If you are a Bamboo plugin developer, see our Bamboo API Changes by Version guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

Recommended upgrade path

<table>
<thead>
<tr>
<th>update path</th>
<th>When upgrading from Bamboo 4.0 and later, you can upgrade directly to the latest version of Bamboo:</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.0 + 5.14</td>
<td>When upgrading from earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo latest version:</td>
</tr>
<tr>
<td>PRE 4.0 5.0–5.7 5.14</td>
<td>When upgrading from very old versions of Bamboo you must follow this upgrade path:</td>
</tr>
</tbody>
</table>
Before you begin

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

The installation path is referred to as `<bamboo-install>` and points to the directory into which you extracted the Bamboo package. It is different from `<bamboo-home>`, which points to the directory where Bamboo data is stored.

1. Export and back up the existing Bamboo data

Export the Bamboo database

There are two database backup scenarios, depending on whether you are using an embedded or external database.

<table>
<thead>
<tr>
<th>Embedded HSQL database</th>
<th>External database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an export .zip file for the original Bamboo instance. For more information, see Exporting data for backup. The export may take a long time to complete and may require a large amount of disk space, depending on the number of builds and tests in your system.</td>
<td>Use native database tools to create a backup. For more information about external databases, see Connecting Bamboo to an external database.</td>
</tr>
</tbody>
</table>

HSQl is not recommended for production Bamboo instances.

Stop Bamboo

Stop the original Bamboo instance.

If you have Bamboo running as a Windows service, uninstall the service by using the UninstallService.bat executable that came with your Bamboo instance.

Back up the Bamboo configuration

When the original Bamboo instance is shut down, back up your `<bamboo-home>` directory, which contains the builds and configuration directories. You can compress it into a .zip file.

- Viewing Bamboo paths
  - Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path:
1. For more information about these directories, see Important Directories and Files.

2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a `<bamboo-install>` directory that is different from the `<bamboo-install>` directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- Make sure that the original Bamboo instance is not running before you start the new installation.
- To prevent data loss during updates or reinstallation, the `<bamboo-home>` directory must be different from the `<bamboo-install>` directory.

The guidelines for the new Bamboo instance installation are the following:

Mac OS X

- The Mac installer deletes the previous version of Bamboo.
- Follow the Mac OS X install instructions.

Linux

- Delete your old `<bamboo-install>` directory to remove any legacy files.
- Follow the Linux install instructions.

Windows

- The Windows installer deletes the previous version of Bamboo.
- Follow the Windows install instructions.
- Configure Bamboo to run as a service on Windows, using the `service.bat` executable.

3. Configure the new Bamboo instance

Set the home directory for the new Bamboo instance

Set the `<home-directory>` to use the `<home-directory>` of the original Bamboo instance:

1. Go to the new Bamboo instance `<bamboo-install>` directory. It is the directory where you installed Bamboo.
2. Open `atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`

For Bamboo versions prior to 5.1, the file path is: `<bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties`

3. Set the `bamboo.home` variable to use the `<bamboo-home>` path of the original Bamboo instance.

Reconnect external user directories (optional)
If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance.

For more information, see Integrating Crowd with Bamboo and Integrating Bamboo with LDAP.

**Update any installed add-ons**

If you installed any add-ons in addition to the pre-installed system add-ons:

- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

**Automatic update of remote agents**

For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.

For more information, see Bamboo remote agent installation guide.

**Configure the context path**

If you had a context path configured for the original Bamboo instance (http://hostname:[port]/context_path), you have to configure it for the new Bamboo instance. For more information, see Changing Bamboo's root context path.

**Check database access permission**

Before you start the new Bamboo instance, make sure that it has the write access to the database, which is required to complete the upgrade tasks.

4. **Start Bamboo**

Start Bamboo

Once you have installed Bamboo and set the bamboo.home property, start the new Bamboo instance. The upgrade runs automatically.

You can check whether the upgrade was successful in the atlassian-bamboo.log file.

---

### Version-specific upgrade notes

The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

- Upgrading to Bamboo 5.14
- Upgrading to Bamboo 5.13
- Upgrading to Bamboo 5.12
- Upgrading to Bamboo 5.11
- Upgrading to Bamboo 5.10
- Upgrading to Bamboo 5.9
- Upgrading to Bamboo 5.8
- Upgrading to Bamboo 5.7
- Upgrading to Bamboo 5.6
- Upgrading to Bamboo 5.5
- Upgrading to Bamboo 5.4

**Upgrading to Bamboo 5.14**

**New API for VCS repositories**

We’ve rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

---

Action required

Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you're using any plugins that...
aren't officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian Marketplace).

Plugins that are particularly prone to incompatibilities and require special attention are those that deal with:

- automatic plan creation and management
- automatic plan branch creation and management
- repository configuration management

We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.

For details about the API changes, see our developer documentation.

Changes in requirements for table names of the external databases

With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:

- Upgrading to Bamboo 5.13 below
- MySQL
- Bamboo 5.13 Release Notes

See also

- the general update steps section above.
- Bamboo 5.14 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

### Upgrading to Bamboo 5.13

Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Database</th>
<th>Verification Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft SQL Server</td>
<td>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see Microsoft SQL Server.</td>
</tr>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to Connecting Bamboo to an external database. For MySQL specifically, this might affect all databases in the instance, see MySQL documentation.</td>
</tr>
</tbody>
</table>

**If the check fails**

If the check fails and you can't correct your database configuration immediately, you can roll back to the previous installed version of Bamboo without changing anything in your database or home directory configuration.

See also:

- the general update steps section above
- Bamboo 5.13 Release Notes
- the Bamboo Supported platforms page

You might also want to check our developer documentation.

### Upgrading to Bamboo 5.12

See:

- the general update steps section above
- Bamboo 5.12 Release Notes
- the Bamboo Supported platforms page

You might also want to check our developer documentation.

### Upgrading to Bamboo 5.11

See:

- the general update steps section above
- Bamboo 5.11 Release Notes
- the Bamboo Supported platforms page
Documentation for Bamboo 6.7

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

**Upgrading to Bamboo 5.10**

See:

- the general update steps section above
- Bamboo 5.10 Release Notes
- the Bamboo Supported platforms page

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

**Upgrading to Bamboo 5.9**

See also:

- the general update steps section above
- Bamboo 5.9 Release Notes
- the Bamboo Supported platforms page

Changes to Clover Plugin integration

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before). Automatic Clover integration will not happen when your Maven task contains the `install` or `deploy` commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the `install` or `deploy` Maven commands. If they do: either disable automatic Clover integration for those jobs, or change the phase to the `verify` command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover's coverage reports.

**Upgrading to Bamboo 5.8**

See also:

- the general update steps section above
- Bamboo 5.8 Release Notes
- the Bamboo Supported platforms page

If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

**Hibernate dialect update**

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the `bamboo.cfg.xml` file. The new dialects are:

- `org.hibernate.dialect.PostgreSQLDialect`
- `org.hibernate.dialect.HSQLDialect`
- `org.hibernate.dialect.Oracle10gDialect`
- `org.hibernate.dialect.MySQL5Dialect`
- `com.atlassian.bamboo.hibernate.SQLServerIntlDialect`

**Upgrading to Bamboo 5.7**

See also:

- the general update steps section above
- Bamboo 5.7 Release Notes
- the Bamboo Supported platforms page
Global deployment expiry
If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7.
Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be removed. Most likely this is what you want but it's important to be aware of this change.
Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release.
Read more about global expiry in Bamboo 5.7.

Upgrading to Bamboo 5.6

See also:
- the general update steps section above
- Bamboo 5.6 Release Notes
- the Bamboo Supported platforms page

Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated
Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on Bitbucket Server.

Update time
When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the VARIABLE_CONTEXT table. For a more precise calculation, assume that 10 minutes are needed to process 15 million records in that table.

Installer package on MAC OS X can not be opened due to code signing requirements
Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.6.
Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.
The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available here.

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

Upgrading to Bamboo 5.5

- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket servers. If you have previously integrated Bamboo with Bitbucket Server, you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but OAuth is a better as it is an impersonating authentication type. For more information, see Configuring authentication for an application link.
- Git will use --ancestry-path when trying to extract changeset due to

Please see BAM-13760 - Too many notifications for release -> feature merge in Git plan branches for more information.

Since that command is available for Git 1.7.2 and above (see Release Notes), please update your native Git, if you have Git 1.7.1 installed (especially those who use RHEL 6 or CentOS).

See also:
- the general update steps section above
- Bamboo 5.5 Release Notes
- the Bamboo Supported platforms page

Installer package on MAC OS X can not be opened due to code signing requirements
Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.5.
Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.
The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.
Upgrading to Bamboo 5.4

Note that Bamboo will run a full reindex after updating.

See also:
- the general update steps section above
- Bamboo 5.4 release notes
- the Bamboo Supported platforms page

Installer package on MAC OS X can not be opened due to code signing requirements

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn’t from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see -

BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X [RESOLVED] for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

Troubleshooting

If you followed the documentation and you still have problems with the upgrade process:

- Check the How to Upgrade/Migrate Bamboo article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- You can also create a support ticket. To help us address the issue, attach the atlassian-bamboo.log file to the ticket.

Bamboo upgrade guide v5.15

You can upgrade Bamboo by installing a new version of Bamboo and setting it up with the configuration of the original Bamboo instance.

On this page

- Overview
- Recommended upgrade path
- 1. Export and back up the existing Bamboo data
- 2. Download and install a new Bamboo instance
- 3. Configure the new Bamboo instance
- 4. Start Bamboo
- Version-specific upgrade notes
- Troubleshooting

Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page. Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>1. Clone your Bamboo instance into the new location. 2. Perform the upgrade steps on the cloned Bamboo instance as described on this page. The cloned instance on the new server is referred to as original Bamboo instance.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.
We recommend that you test the Bamboo upgrade on a QA server before deploying to production.

If you are a Bamboo plugin developer, see our Bamboo API Changes by Version guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

Recommended upgrade path

**update path**
When upgrading from Bamboo 4.0 and later, you can upgrade directly to the latest version of Bamboo:

- **4.0 +**
- **5.15**

When upgrading from earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo latest version:

- **PRE 4.0**
- **5.0–5.7**
- **5.15**

When upgrading from very old versions of Bamboo you must follow this upgrade path:

- **OLDER VERSIONS**
  - **2.0.6**
  - **2.6.3**
  - **2.7.4**
  - **5.0–5.7**
  - **5.15**

You do not need to downgrade before upgrading.

---

Due to a known issue with upgrading Bamboo 4.x to Bamboo 5.15, you must first upgrade to Bamboo 5.14.x and then proceed with further upgrades.

---

**Before you begin**

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

**The installation path is referred to as** `<bamboo-install>` **and points to the directory into which you extracted the Bamboo package. It is different from** `<bamboo-home>`, **which points to the directory where Bamboo data is stored.**

1. **Export and back up the existing Bamboo data**

**Export the Bamboo database**

There are two database backup scenarios, depending on whether you are using an embedded or external database.

<table>
<thead>
<tr>
<th>Embedded HSQL database</th>
<th>External database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an export .zip file for the original Bamboo instance. For more information, see Exporting data for backup. The export may take a long time to complete and may require a large amount of disk space, depending on the number of builds and tests in your system.</td>
<td>Use native database tools to create a backup. For more information about external databases, see Connecting Bamboo to an external database.</td>
</tr>
</tbody>
</table>

- HSQL is not recommended for production Bamboo instances.

**Stop Bamboo**

Stop the original Bamboo instance. If you have Bamboo running as a Windows service, uninstall the service by using the `UninstallService.bat` executable that came with your Bamboo instance.
Back up the Bamboo configuration

When the original Bamboo instance is shut down, back up your `<bamboo-home>` directory, which contains the builds and configuration directories. You can compress it into a .zip file.

Viewing Bamboo paths

Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path:

![Bamboo paths diagram]

For more information about these directories, see Important Directories and Files.

2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a `<bamboo-install>` directory that is different from the `<bamboo-install>` directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- Make sure that the original Bamboo instance is not running before you start the new installation.
- To prevent data loss during updates or reinstallation, the `<bamboo-home>` directory must be different from the `<bamboo-install>` directory.

The guidelines for the new Bamboo instance installation are the following:

Mac OS X

- The Mac installer deletes the previous version of Bamboo.
- Follow the Mac OS X install instructions.

Linux

- Delete your old `<Bamboo-install>` directory to remove any legacy files.
- Follow the Linux install instructions.

Windows

- The Windows installer deletes the previous version of Bamboo.
- Follow the Windows install instructions.
- Configure Bamboo to run as a service on Windows, using the `service.bat` executable.

3. Configure the new Bamboo instance

Set the home directory for the new Bamboo instance

Set the `<home-directory>` to use the `<home-directory>` of the original Bamboo instance:

1. Go to the new Bamboo instance `<bamboo-install>` directory. It is the directory where you installed Bamboo.
2. Open `/atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`
3. Set the `bamboo.home` variable to use the `<bamboo-home>` path of the original Bamboo instance.

**Reconnect external user directories (optional)**

If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance.

For more information, see [Integrating Crowd with Bamboo](#) and [Integrating Bamboo with LDAP](#).

**Update any installed add-ons**

If you installed any add-ons in addition to the pre-installed system add-ons:

- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

**Automatic update of remote agents**

For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.

For more information, see [Bamboo remote agent installation guide](#).

**Configure the context path**

If you had a context path configured for the original Bamboo instance (`http://hostname:[port]/context_path`), you have to configure it for the new Bamboo instance. For more information, see [Changing Bamboo’s root context path](#).

**Check database access permission**

Before you start the new Bamboo instance, make sure that it has the write access to the database, which is required to complete the upgrade tasks.

4. **Start Bamboo**

Start Bamboo

Once you have installed Bamboo and set the `bamboo.home` property, start the new Bamboo instance. The upgrade runs automatically.

You can check whether the upgrade was successful in the `atlassian-bamboo.log` file.

---

**Upgrading Bamboo may require reindexing.**

Depending on the number of existing builds and tests, the reindexing process may take a significant amount of time, during which Bamboo will not be available.

---

**Version-specific upgrade notes**

The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

- Upgrading to Bamboo 5.15
- Upgrading to Bamboo 5.14
- Upgrading to Bamboo 5.13
- Upgrading to Bamboo 5.12
- Upgrading to Bamboo 5.11
- Upgrading to Bamboo 5.10
- Upgrading to Bamboo 5.9
- Upgrading to Bamboo 5.8
- Upgrading to Bamboo 5.7
- Upgrading to Bamboo 5.6
- Upgrading to Bamboo 5.5
- Upgrading to Bamboo 5.4
**Upgrading to Bamboo 5.15**
Bamboo 5.15 contains upgrade tasks that can take extra time when moving from earlier versions of Bamboo. Keep this in mind when planning your upgrade outages.

**Upgrading to Bamboo 5.14**

**New API for VCS repositories**
We've rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

![Action required](image)
**Action required**
Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you're using any plugins that aren't officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian Marketplace).

Plugins that are particularly prone to incompatibilities and require special attention are those that deal with:
- automatic plan creation and management
- automatic plan branch creation and management
- repository configuration management

We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.

For details about the API changes, see our developer documentation.

**Changes in requirements for table names of the external databases**
With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:

- Upgrading to Bamboo 5.13 below
- MySQL
- Bamboo 5.13 Release Notes

See also:
- the general update steps section above.
- Bamboo 5.14 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

**Upgrading to Bamboo 5.13**

Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft SQL Server</td>
<td>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see Microsoft SQL Server.</td>
</tr>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to Connecting Bamboo to an external database. For MySQL specifically, this might affect all databases in the instance, see MySQL documentation.</td>
</tr>
</tbody>
</table>

**If the check fails**
If the check fails and you can't correct your database configuration immediately, you can roll back to the previous installed version of Bamboo without changing anything in your database or home directory configuration.

See also:
- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

**Upgrading to Bamboo 5.12**

See:
Upgrading to Bamboo 5.11

See:

- the general update steps section above.
- Bamboo 5.11 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.10

See:

- the general update steps section above.
- Bamboo 5.10 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.9

See also:

- the general update steps section above.
- the Bamboo 5.9 Release Notes.
- the Bamboo Supported platforms page.

Changes to Clover Plugin integration

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before). Automatic Clover integration will not happen when your Maven task contains the `install` or `deploy` commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the `install` or `deploy` Maven commands. If they do: either disable automatic Clover integration for those jobs, or change the phase to the `verify` command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover’s coverage reports.

Upgrading to Bamboo 5.8

See also:

- the general update steps section above.
- the Bamboo 5.8 Release Notes.
- the Bamboo Supported platforms page.

If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

Hibernate dialect update

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the `bamboo.cfg.xml` file. The new dialects are:
**Upgrading to Bamboo 5.7**

See also:

- the general update steps section above.
- the Bamboo 5.7 Release Notes.
- the Bamboo Supported platforms page.

**Global deployment expiry**

If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7. Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be removed. Most likely this is what you want but it’s important to be aware of this change.

Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release.

Read more about global expiry in Bamboo 5.7.

**Upgrading to Bamboo 5.6**

See also:

- the general update steps section above.
- the Bamboo 5.6 Release Notes.
- the Bamboo Supported platforms page.

**Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated**

Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on [Bitbucket Server](https://bitbucket.org).

**Update time**

When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the VARIABLE_CONTEXT table. For a more precise calculation, assume that 10 minutes are needed to process 15 million records in that table.

**Installer package on MAC OS X can not be opened due to code signing requirements**

*Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.6.*

Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn’t from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

---

<table>
<thead>
<tr>
<th><strong>BAM-11742</strong> - Installer package is &quot;damaged and cannot be reopened&quot; on Mac OS X</th>
<th>RESOLVED</th>
</tr>
</thead>
</table>

Please see information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available [here](https://bitbucket.org).

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

**Upgrading to Bamboo 5.5**

- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket Server. If you have previously integrated Bamboo with Bitbucket Server, you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but
OAuth is a better as it is an impersonating authentication type. For more information, see Configuring authentication for an application link.

- Git will use `--ancestry-path` when trying to extract changeset due to

  **BAM-13760** - Too many notifications for release -> feature merge in Git plan branches

  Since that command is available for Git 1.7.2 and above (see Release Notes), please update your native Git, if you have Git 1.7.1 installed (especially those who use RHEL 6 or CentOS).

See also:

- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

**Installer package on MAC OS X can not be opened due to code signing requirements**

*Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.5.*

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn’t from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see -

**BAM-11742** - Installer package is “damaged and cannot be reopened” on Mac OS X  

- The Mac installer will not be available until this has been resolved
- There is a temporary work-around available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

### Upgrading to Bamboo 5.4

Note that Bamboo will run a full reindex after updating.

See also:

- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

**Installer package on MAC OS X can not be opened due to code signing requirements**

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn’t from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see -

**BAM-11742** - Installer package is "damaged and cannot be reopened" on Mac OS X  

- The Mac installer will not be available until this has been resolved
- There is a temporary work-around solution available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

### Troubleshooting

If you followed the documentation and you still have problems with the upgrade process:

- Check the How to Upgrade/Migrate Bamboo article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- Ask questions at [https://answers.atlassian.com](https://answers.atlassian.com).
- You can also create a support ticket. To help us address the issue, attach the atlassian-bamboo.log file to the ticket.

### Bamboo upgrade guide v6.0

You can upgrade Bamboo by installing a new version of Bamboo and setting it up with the configuration of the original Bamboo instance.

### On this page

- Overview
- Recommended upgrade path
Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page.</td>
<td>1. Clone your Bamboo instance into the new location.</td>
</tr>
<tr>
<td>Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>2. Perform the upgrade steps on the cloned Bamboo instance as described on this page.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.

We recommend that you test the Bamboo upgrade on a QA server before deploying to production.

If you are a Bamboo plugin developer, see our Bamboo API Changes by Version guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

Recommended upgrade path

<table>
<thead>
<tr>
<th>Upgrade path</th>
</tr>
</thead>
<tbody>
<tr>
<td>When upgrading from Bamboo 5.0 and later, you can upgrade directly to the latest version of Bamboo:</td>
</tr>
<tr>
<td>5.0 +</td>
</tr>
<tr>
<td>When upgrading from earlier than Bamboo 5.0, you must upgrade to any of Bamboo 5.0–5.14 before upgrading to Bamboo latest version:</td>
</tr>
<tr>
<td>4.0–4.4</td>
</tr>
<tr>
<td>When upgrading from very old versions of Bamboo you must follow this upgrade path:</td>
</tr>
<tr>
<td>OLDER VERSIONS</td>
</tr>
</tbody>
</table>

You do not need to downgrade before upgrading.

Before you begin

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

The installation path is referred to as `<bamboo-install>` and points to the directory into which you extracted the Bamboo package. It is different from `<bamboo-home>`, which points to the directory where Bamboo data is stored.

1. Export and back up the existing Bamboo data

Export the Bamboo database

There are two database backup scenarios, depending on whether you are using an embedded or external database.

| Embedded HSQL database | External database |
Stop Bamboo

Stop the original Bamboo instance.

If you have Bamboo running as a Windows service, uninstall the service by using the UninstallService.bat executable that came with your Bamboo instance.

Back up the Bamboo configuration

When the original Bamboo instance is shut down, back up your <bamboo-home> directory, which contains the builds and configuration directories. You can compress it into a .zip file.

Viewing Bamboo paths

Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path:

```
Bamboo paths

Current running /Volumes/Pharlap/opt/dogfood/panda
directory
Configuration path /Volumes/Pharlap/opt/dogfood/panda/home/xml-data/configuration
Build path /Volumes/Pharlap/opt/dogfood/panda/home/xml-data/builds
Build working /Volumes/Pharlap/opt/dogfood/panda/home/xml-data/build-dir
directory
Artifacts directory /Volumes/Pharlap/opt/dogfood/panda/home/artifacts
Bamboo home /Volumes/Pharlap/opt/dogfood/panda/home
Bamboo logs /Volumes/Pharlap/opt/dogfood/panda/home/logs/atlassian-bamboo.log
Temporary directory /Volumes/Pharlap/opt/dogfood/panda/tmp
User home /Users/atlassian
```

For more information about these directories, see Important Directories and Files.

2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a <bamboo-install> directory that is different from the <bamboo-install> directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- Make sure that the original Bamboo instance is not running before you start the new installation.
- To prevent data loss during updates or reinstallation, the <bamboo-home> directory must be different from the <bamboo-install> directory.

The guidelines for the new Bamboo instance installation are the following:

Mac OS X

- The Mac installer deletes the previous version of Bamboo.
- Follow the Mac OS X install instructions.

Linux

- Delete your old <Bamboo-install> directory to remove any legacy files.
- Follow the Linux install instructions.
3. Configure the new Bamboo instance

Set the home directory for the new Bamboo instance

Set the `<home-directory>` to use the `<home-directory>` of the original Bamboo instance:

1. Go to the new Bamboo instance `<bamboo-install>` directory. It is the directory where you installed Bamboo.
2. Open `atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`

For Bamboo versions prior to 5.1, the file path is: `<bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties`

3. Set the `bamboo.home` variable to use the `<bamboo-home>` path of the original Bamboo instance.

Reconnect external user directories (optional)

If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance.

For more information, see Integrating Crowd with Bamboo and Integrating Bamboo with LDAP.

Update any installed add-ons

If you installed any add-ons in addition to the pre-installed system add-ons:

- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

Automatic update of remote agents

For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.

For more information, see Bamboo remote agent installation guide.

Configure the context path

If you had a context path configured for the original Bamboo instance [hostname:port/context_path], you have to configure it for the new Bamboo instance. For more information, see Changing Bamboo's root context path.

Check database access permission

Before you start the new Bamboo instance, make sure that it has the write access to the database, which is required to complete the upgrade tasks.

4. Start Bamboo

Start Bamboo

Once you have installed Bamboo and set the `bamboo.home` property, start the new Bamboo instance. The upgrade runs automatically.

You can check whether the upgrade was successful in the `atlassian-bamboo.log` file.

Upgrading Bamboo may require reindexing.

Depending on the number of existing builds and tests, the reindexing process may take a significant amount of time, during which Bamboo will not be available.
Version-specific upgrade notes

The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

- Upgrading to Bamboo 6.0
- Upgrading to Bamboo 5.15
- Upgrading to Bamboo 5.14
- Upgrading to Bamboo 5.13
- Upgrading to Bamboo 5.12
- Upgrading to Bamboo 5.11
- Upgrading to Bamboo 5.10
- Upgrading to Bamboo 5.9
- Upgrading to Bamboo 5.8
- Upgrading to Bamboo 5.7
- Upgrading to Bamboo 5.6
- Upgrading to Bamboo 5.5
- Upgrading to Bamboo 5.4

**Upgrading to Bamboo 6.0**

**Microsoft JDBC driver**

With Bamboo 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver.

If database settings are configured directory in Bamboo, then during 6.0 upgrade it will attempt to update driver settings. In case of customized settings Bamboo instance administrator will be required to manually convert the settings.

If database settings are configured in the container (Tomcat) and Bamboo uses datasource, automatic upgrade will not be possible and instance administration will be required to manually convert the settings.

To learn more about this change, see here.

**New library for setting up a JNDI resource for SMTP**

Bamboo 6.0 is shipped with the `javax.mail-api-1.5.6.jar` library. This library needs to be copied over to your `<Bamboo-install>/lib` folder when setting up a JNDI resource for SMTP. For more information, see here.

**Changes to Git support**

Starting from version 6.0, Bamboo changes support for Git to version 1.8.1.5 or later.

**Upgrading to Bamboo 5.15**

Bamboo 5.15 contains upgrade tasks that can take extra time when moving from earlier versions of Bamboo. Keep this in mind when planning your upgrade outages.

**Upgrading to Bamboo 5.14**

**New API for VCS repositories**

We've rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

**Action required**

Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you're using any plugins that aren't officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian Marketplace).

Plugins that are particularly prone to incompatibilities and require special attention are those that deal with:

- automatic plan creation and management
- automatic plan branch creation and management
- repository configuration management

We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.

For details about the API changes, see our developer documentation.

**Changes in requirements for table names of the external databases**

With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:
Upgrading to Bamboo 5.13

Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Microsoft SQL Server</th>
<th>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see Microsoft SQL Server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to Connecting Bamboo to an external database. For MySQL specifically, this might affect all databases in the instance, see MySQL documentation.</td>
</tr>
</tbody>
</table>

If the check fails

If the check fails and you can't correct your database configuration immediately, you can roll back to the previous installed version of Bamboo without changing anything in your database or home directory configuration.

See also:

- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.12

See:

- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.11

See:

- the general update steps section above.
- Bamboo 5.11 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.10

See:

- the general update steps section above.
- Bamboo 5.10 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.
**Upgrading to Bamboo 5.9**

See also:
- the general update steps section above.
- the Bamboo 5.9 Release Notes.
- the Bamboo Supported platforms page.

Changes to Clover Plugin integration

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before). Automatic Clover integration will not happen when your Maven task contains the install or deploy Maven commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the install or deploy Maven commands. If they do: either disable automatic Clover integration for those jobs, or change the phase to the verify command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover's coverage reports.

**Upgrading to Bamboo 5.8**

See also:
- the general update steps section above.
- the Bamboo 5.8 Release Notes.
- the Bamboo Supported platforms page.

If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

**Hibernate dialect update**

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the `bamboo.cfg.xml` file. The new dialects are:

```plaintext
org.hibernate.dialect.PostgreSQLDialect
org.hibernate.dialect.HSQLDialect
org.hibernate.dialect.Oracle10gDialect
org.hibernate.dialect.MySQL5Dialect
com.atlassian.bamboo.hibernate.SQLServerIntlDialect
```

**Upgrading to Bamboo 5.7**

See also:
- the general update steps section above.
- the Bamboo 5.7 Release Notes.
- the Bamboo Supported platforms page.

**Global deployment expiry**

If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7.

Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be removed. Most likely this is what you want but it's important to be aware of this change.

Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release. Read more about global expiry in Bamboo 5.7.

**Upgrading to Bamboo 5.6**

See also:
- the general update steps section above.
- the Bamboo 5.6 Release Notes.
- the Bamboo Supported platforms page.
Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated

Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on [Bitbucket Server](https://docs.atlassian.com/bitbucket_SERVER/6.7/).

**Update time**

When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the VARIABLE_CONTEXT table. For a more precise calculation, assume that 10 minutes are needed to process 15 million records in that table.

**Installer package on MAC OS X cannot be opened due to code signing requirements**

*Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.6.*

Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID. Please see [BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X](https://jira.atlassian.com/browse/BAM-11742) for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available [here](https://jira.atlassian.com/browse/BAM-11742).

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

**Upgrading to Bamboo 5.5**

- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket servers. If you have previously [integrated Bamboo with Bitbucket Server](https://docs.atlassian.com/bamboo/latest), you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but OAuth is a better as it is an impersonating authentication type. For more information, see [Configuring authentication for an application link](https://docs.atlassian.com/bamboo/latest).
- Git will use `--ancestry-path` when trying to extract changeset due to [BAM-13760 - Too many notifications for release -> feature merge in Git plan branches](https://jira.atlassian.com/browse/BAM-13760). Since that command is available for Git 1.7.2 and above (see [Release Notes](https://confluence.atlassian.com/display/BB57/Release+Notes)), please update your native Git, if you have Git 1.7.1 installed (especially those who use RHEL 6 or CentOS).

See also:

- the general [update steps](https://docs.atlassian.com/bamboo/latest) section above.
- the Bamboo [5.5 release notes](https://confluence.atlassian.com/display/BB57/Release+Notes).
- the Bamboo [Supported platforms](https://confluence.atlassian.com/display/BB57/Supported+Platforms) page.

**Installer package on MAC OS X cannot be opened due to code signing requirements**

*Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.5.*

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn’t from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID. Please see [BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X](https://jira.atlassian.com/browse/BAM-11742) for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available [here](https://jira.atlassian.com/browse/BAM-11742).

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

**Upgrading to Bamboo 5.4**

Note that Bamboo will run a full reindex after updating.

See also:

- the general [update steps](https://docs.atlassian.com/bamboo/latest) section above.
- the Bamboo [5.5 release notes](https://confluence.atlassian.com/display/BB57/Release+Notes).
Installer package on MAC OS X can not be opened due to code signing requirements

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see -

**BAM-11742** - Installer package is "damaged and cannot be reopened" on Mac OS X [RESOLVED] for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around solution available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

### Troubleshooting

If you followed the documentation and you still have problems with the upgrade process:

- Check the How to Upgrade/Migrate Bamboo article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- You can also create a support ticket. To help us address the issue, attach the `atlassian-bamboo.log` file to the ticket.

### Bamboo upgrade guide v6.1

You can upgrade Bamboo by installing a new version of Bamboo and setting it up with the configuration of the original Bamboo instance.

---

### Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page. Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>1. Clone your Bamboo instance into the new location. 2. Perform the upgrade steps on the cloned Bamboo instance as described on this page. The cloned instance on the new server is referred to as original Bamboo instance.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.

**We recommend that you test the Bamboo upgrade on a QA server before deploying to production.**

If you are a Bamboo plugin developer, see our Bamboo API Changes by Version guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

### Before you begin

**Determine your upgrade path**

- When upgrading from very old versions of Bamboo you must follow this upgrade path:
Before you begin

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

The installation path is referred to as `<bamboo-install>` and points to the directory into which you extracted the Bamboo package. It is different from `<bamboo-home>`, which points to the directory where Bamboo data is stored.

1. Export and back up the existing Bamboo data

Export the Bamboo database

There are two database backup scenarios, depending on whether you are using an embedded or external database.

<table>
<thead>
<tr>
<th>Embedded HSQL database</th>
<th>External database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an export .zip file for the original Bamboo instance. For more information, see Exporting data for backup. The export may take a long time to complete and may require a large amount of disk space, depending on the number of builds and tests in your system.</td>
<td>Use native database tools to create a backup. For more information about external databases, see Connecting Bamboo to an external database.</td>
</tr>
</tbody>
</table>

HSQL is not recommended for production Bamboo instances.

Stop Bamboo

Stop the original Bamboo instance.

If you have Bamboo running as a Windows service, uninstall the service by using the UninstallService.bat executable that came with your Bamboo instance.

Back up the Bamboo configuration

When the original Bamboo instance is shut down, back up your `<bamboo-home>` directory, which contains the `builds` and `configuration` directories. You can compress it into a .zip file.

Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path.
### 2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a `<bamboo-install>` directory that is different from the `<bamboo-install>` directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- **Make sure that the original Bamboo instance is not running before you start the new installation.**
- **To prevent data loss during updates or reinstallation, the `<bamboo-home>` directory must be different from the `<bamboo-install>` directory.**

The guidelines for the new Bamboo instance installation are the following:

**Mac OS X**
- The Mac installer deletes the previous version of Bamboo.
- Follow the [Mac OS X install instructions](#).

**Linux**
- Delete your old `<Bamboo-install>` directory to remove any legacy files.
- Follow the [Linux install instructions](#).

**Windows**
- The Windows installer deletes the previous version of Bamboo.
- Follow the [Windows install instructions](#).
- Configure Bamboo to run as a service on Windows, using the `service.bat` executable.

### 3. Configure the new Bamboo instance

Set the home directory for the new Bamboo instance

**Set the `<home-directory>` to use the `<home-directory>` of the original Bamboo instance:**

1. Go to the new Bamboo instance `<bamboo-install>` directory. It is the directory where you installed Bamboo.
2. Open `atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`

   **For Bamboo versions prior to 5.1, the file path is:** `<bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties`

3. Set the `bamboo.home` variable to use the `<bamboo-home>` path of the original Bamboo instance.

**Reconnect external user directories (optional)**
If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance.

For more information, see Integrating Crowd with Bamboo and Integrating Bamboo with LDAP.

### Update any installed add-ons

If you installed any add-ons in addition to the pre-installed system add-ons:

- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

### Automatic update of remote agents

For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.

For more information, see Bamboo remote agent installation guide.

### Configure the context path

If you had a context path configured for the original Bamboo instance (http://hostname:[port]/context_path), you have to configure it for the new Bamboo instance. For more information, see Changing Bamboo's root context path.

### Check database access permission

Before you start the new Bamboo instance, make sure that it has the write access to the database, which is required to complete the upgrade tasks.

### 4. Start Bamboo

Start Bamboo

Once you have installed Bamboo and set the `bamboo.home` property, start the new Bamboo instance. The upgrade runs automatically.

You can check whether the upgrade was successful in the `atlassian-bamboo.log` file.

Upgrading Bamboo may require reindexing.

Depending on the number of existing builds and tests, the reindexing process may take a significant amount of time, during which Bamboo will not be available.

### Version-specific upgrade notes

The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

- Determine your upgrade path
- Before you begin
- Upgrading to Bamboo 6.1
- Upgrading to Bamboo 6.0
- Upgrading to Bamboo 5.15
- Upgrading to Bamboo 5.14
- Upgrading to Bamboo 5.13
- Upgrading to Bamboo 5.12
- Upgrading to Bamboo 5.11
- Upgrading to Bamboo 5.10
- Upgrading to Bamboo 5.9
- Upgrading to Bamboo 5.8
- Upgrading to Bamboo 5.7
- Upgrading to Bamboo 5.6
- Upgrading to Bamboo 5.5
- Upgrading to Bamboo 5.4

### Upgrading to Bamboo 6.1

See also:

- the general update steps section above.
- Bamboo 6.1 Release Notes
You might also want to check our Bamboo Specs reference documentation.

**Upgrading to Bamboo 6.0**

**Microsoft JDBC driver**

With Bamboo 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver.

If database settings are configured directory in Bamboo, then during 6.0 upgrade it will attempt to update driver settings. In case of customized settings Bamboo instance administrator will be required to manually convert the settings.

If database settings are configured in the container (Tomcat) and Bamboo uses datasource, automatic upgrade will not be possible and instance administration will be required to manually convert the settings.

To learn more about this change, see here.

**New library for setting up a JNDI resource for SMTP**

Bamboo 6.0 is shipped with the jersey.mail-api-1.5.6.jar library. This library needs to copied over to your `<Bamboo-install>/lib` folder when setting up a JNDI resource for SMTP. For more information, see here.

**Changes to Git support**

Starting from version 6.0, Bamboo changes support for Git to version 1.8.1.5 or later.

**Upgrading to Bamboo 5.15**

Bamboo 5.15 contains upgrade tasks that can take extra time when moving from earlier versions of Bamboo. Keep this in mind when planning your upgrade outages.

**Upgrading to Bamboo 5.14**

**New API for VCS repositories**

We've rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

**Action required**

Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you're using any plugins that aren't officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian Marketplace).

Plugins that are particularly prone to incompatibilities and require special attention are those that deal with:

- automatic plan creation and management
- automatic plan branch creation and management
- repository configuration management

We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.

For details about the API changes, see our developer documentation.

**Changes in requirements for table names of the external databases**

With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:

- Upgrading to Bamboo 5.13 below
- MySQL
- Bamboo 5.13 Release Notes

**See also**

- the general update steps section above.
- Bamboo 5.14 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

**Upgrading to Bamboo 5.13**
Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft SQL Server</td>
<td>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see Microsoft SQL Server.</td>
</tr>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to Connecting Bamboo to an external database. For MySQL specifically, this might affect all databases in the instance, see MySQL documentation.</td>
</tr>
</tbody>
</table>

If the check fails

If the check fails and you can't correct your database configuration immediately, you can roll back to the previous installed version of Bamboo without changing anything in your database or home directory configuration.

See also:

- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.12

See:

- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.11

See:

- the general update steps section above.
- Bamboo 5.11 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.10

See:

- the general update steps section above.
- Bamboo 5.10 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.9

See also:

- the general update steps section above.
- the Bamboo 5.9 Release Notes.
- the Bamboo Supported platforms page.

Changes to Clover Plugin integration

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before).
Automatic Clover integration will not happen when your Maven task contains the `install` or `deploy` commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the `install` or `deploy` Maven commands. If they do: either disable automatic Clover integration for those jobs, or change the phase to the `verify` command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover’s coverage reports.

### Upgrading to Bamboo 5.8

See also:
- the general update steps section above.
- the Bamboo 5.8 Release Notes.
- the Bamboo Supported platforms page.

If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

**Hibernate dialect update**

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the `bamboo.cfg.xml` file. The new dialects are:

- `org.hibernate.dialect.PostgreSQLDialect`
- `org.hibernate.dialect.HSQLDialect`
- `org.hibernate.dialect.Oracle10gDialect`
- `org.hibernate.dialect.MySQL5Dialect`
- `com.atlassian.bamboo.hibernate.SQLServerIntlDialect`

### Upgrading to Bamboo 5.7

See also:
- the general update steps section above.
- the Bamboo 5.7 Release Notes.
- the Bamboo Supported platforms page.

**Global deployment expiry**

If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7. Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be removed. Most likely this is what you want but it’s important to be aware of this change. Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release. Read more about global expiry in Bamboo 5.7.

### Upgrading to Bamboo 5.6

See also:
- the general update steps section above.
- the Bamboo 5.6 Release Notes.
- the Bamboo Supported platforms page.

**Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated**

Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on Bitbucket Server.

**Update time**

When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the `VARIABLE_CONTEXT` table. For a more precise calculation, assume that 10 minutes are needed to process 15 million records in that table.

**Installer package on MAC OS X can not be opened due to code signing requirements**

*Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.6.*
Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see [BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X](http://example.com) for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available [here](http://example.com).

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

### Upgrading to Bamboo 5.5

- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket servers. If you have previously integrated Bamboo with Bitbucket Server, you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but OAuth is a better as it is an impersonating authentication type. For more information, see [Configuring authentication for an application link](http://example.com).
- Git will use `--ancestry-path` when trying to extract changeset due to

  [BAM-13760 - Too many notifications for release -> feature merge in Git plan branches](http://example.com) Since that command is available for Git 1.7.2 and above (see [Release Notes](http://example.com)), please update your native Git, if you have Git 1.7.1 installed (especially those who use RHEL 6 or CentOS).

See also:
- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

### Installer package on MAC OS X can not be opened due to code signing requirements

**Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.5.**

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see [BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X](http://example.com) for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available [here](http://example.com).

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

### Upgrading to Bamboo 5.4

Note that Bamboo will run a full reindex after updating.

See also:
- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

### Installer package on MAC OS X can not be opened due to code signing requirements

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see -

[BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X](http://example.com) [RESOLVED] for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around solution available [here](#).
This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

**Troubleshooting**

If you followed the documentation and you still have problems with the upgrade process:

- Check the How to Upgrade/Migrate Bamboo article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- You can also create a support ticket. To help us address the issue, attach the `atlassian-bamboo.log` file to the ticket.

---

**Bamboo upgrade guide v6.2**

You can upgrade Bamboo by installing a new version of Bamboo and setting it up with the configuration of the original Bamboo instance.

### Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page.</td>
<td>1. <strong>Clone your Bamboo instance into the new location.</strong></td>
</tr>
<tr>
<td>Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>2. Perform the upgrade steps on the cloned Bamboo instance as described on this page.</td>
</tr>
<tr>
<td></td>
<td>The cloned instance on the new server is referred to as the original Bamboo instance.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.

We recommend that you test the Bamboo upgrade on a QA server before deploying to production.

If you are a Bamboo plugin developer, see our [Bamboo API Changes by Version](#) guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

**Before you begin**

**Determine your upgrade path**

**Upgrade path**

- When upgrading from very old versions of Bamboo you must follow this upgrade path:

<table>
<thead>
<tr>
<th>OLDER VERSIONS</th>
<th>2.0.6</th>
<th>2.6.3</th>
<th>2.7.4</th>
<th>5.0--5.7</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.2</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- When upgrading from earlier than Bamboo 5.0, you must upgrade to any of Bamboo 5.0--5.14 before upgrading to Bamboo latest version:

<table>
<thead>
<tr>
<th>4.0--4.4</th>
<th>5.0--5.14</th>
<th>6.2</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- When upgrading from Bamboo 5.0 and later, you can upgrade directly to the latest version of Bamboo:

<table>
<thead>
<tr>
<th>5.0 +</th>
<th>6.2</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You do not need to downgrade before upgrading.
Before you begin

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

The installation path is referred to as `<bamboo-install>` and points to the directory into which you extracted the Bamboo package. It is different from `<bamboo-home>`, which points to the directory where Bamboo data is stored.

1. Export and back up the existing Bamboo data

Export the Bamboo database

There are two database backup scenarios, depending on whether you are using an embedded or external database.

<table>
<thead>
<tr>
<th>Embedded HSQL database</th>
<th>External database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an export .zip file for the original Bamboo instance. For more information, see Exporting data for backup.</td>
<td>Use native database tools to create a backup. For more information about external databases, see Connecting Bamboo to an external database.</td>
</tr>
<tr>
<td>The export may take a long time to complete and may require a large amount of disk space, depending on the number of builds and tests in your system.</td>
<td></td>
</tr>
<tr>
<td><strong>HSQl is not recommended for production Bamboo instances.</strong></td>
<td></td>
</tr>
</tbody>
</table>

Stop Bamboo

Stop the original Bamboo instance.

If you have Bamboo running as a Windows service, uninstall the service by using the UninstallService.bat executable that came with your Bamboo instance.

Back up the Bamboo configuration

When the original Bamboo instance is shut down, back up your `<bamboo-home>` directory, which contains the builds and configuration directories. You can compress it into a .zip file.

- Viewing Bamboo paths
  - Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path:

    **Bamboo paths**
    - Current running directory
    - Configuration path
    - Build path
    - Build working directory
    - Artifacts directory
    - Bamboo home
    - Bamboo logs
    - Temporary directory
    - User home

For more information about these directories, see Important Directories and Files.
2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a `<bamboo-install>` directory that is different from the `<bamboo-install>` directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- Make sure that the original Bamboo instance is not running before you start the new installation.
- To prevent data loss during updates or reinstallation, the `<bamboo-home>` directory must be different from the `<bamboo-install>` directory.

The guidelines for the new Bamboo instance installation are the following:

**Mac OS X**

- The Mac installer deletes the previous version of Bamboo.
- Follow the Mac OS X install instructions.

**Linux**

- Delete your old `<Bamboo-install>` directory to remove any legacy files.
- Follow the Linux install instructions.

**Windows**

- The Windows installer deletes the previous version of Bamboo.
- Follow the Windows install instructions.
- Configure Bamboo to run as a service on Windows, using the `service.bat` executable.

3. Configure the new Bamboo instance

Set the home directory for the new Bamboo instance

Set the `<home-directory>` to use the `<home-directory>` of the original Bamboo instance:

1. Go to the new Bamboo instance `<bamboo-install>` directory. It is the directory where you installed Bamboo.
2. Open `atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`

   For Bamboo versions prior to 5.1, the file path is: `<bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties`

3. Set the `bamboo.home` variable to use the `<bamboo-home>` path of the original Bamboo instance.

Reconnect external user directories (optional)

If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance.

For more information, see Integrating Crowd with Bamboo and Integrating Bamboo with LDAP.

Update any installed add-ons

If you installed any add-ons in addition to the pre-installed system add-ons:

- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

Automatic update of remote agents

For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.

For more information, see Bamboo remote agent installation guide.

Configure the context path

Make sure that the original Bamboo instance is not running before you start the new installation.

To prevent data loss during updates or reinstallation, the `<bamboo-home>` directory must be different from the `<bamboo-install>` directory.
If you had a context path configured for the original Bamboo instance ([http://hostname:[port]/context_path](http://hostname:[port]/context_path)), you have to configure it for the new Bamboo instance. For more information, see Changing Bamboo’s root context path.

Check database access permission

Before you start the new Bamboo instance, make sure that it has the write access to the database, which is required to complete the upgrade tasks.

4. Start Bamboo

Start Bamboo

Once you have installed Bamboo and set the bamboo.home property, start the new Bamboo instance. The upgrade runs automatically. You can check whether the upgrade was successful in the `atlassian-bamboo.log` file.

Upgrading Bamboo may require reindexing.

Depending on the number of existing builds and tests, the reindexing process may take a significant amount of time, during which Bamboo will not be available.

Version-specific upgrade notes

The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

- Determine your upgrade path
- Before you begin
- Upgrading to Bamboo 6.2
- Upgrading to Bamboo 6.1
- Upgrading to Bamboo 6.0
- Upgrading to Bamboo 5.15
- Upgrading to Bamboo 5.14
- Upgrading to Bamboo 5.13
- Upgrading to Bamboo 5.12
- Upgrading to Bamboo 5.11
- Upgrading to Bamboo 5.10
- Upgrading to Bamboo 5.9
- Upgrading to Bamboo 5.8
- Upgrading to Bamboo 5.7
- Upgrading to Bamboo 5.6
- Upgrading to Bamboo 5.5
- Upgrading to Bamboo 5.4

**Upgrading to Bamboo 6.2**

See also:

- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

**Upgrading to Bamboo 6.1**

See also:

- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

**Upgrading to Bamboo 6.0**

Microsoft JDBC driver

With Bamboo 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver.

If database settings are configured directory in Bamboo, then during 6.0 upgrade it will attempt to update driver settings. In case of customized settings Bamboo instance administrator will be required to manually convert the settings.
To learn more about this change, see [here](#).

**New library for setting up a JNDI resource for SMTP**

Bamboo 6.0 is shipped with the `javax.mail-api-1.5.6.jar` library. This library needs to be copied over to your `<Bamboo-install>/lib` folder when setting up a JNDI resource for SMTP. For more information, see [here](#).

**Changes to Git support**

Starting from version 6.0, Bamboo changes support for Git to version 1.8.1.5 or later.

**Upgrading to Bamboo 5.15**

Bamboo 5.15 contains upgrade tasks that can take extra time when moving from earlier versions of Bamboo. Keep this in mind when planning your upgrade outages.

**Upgrading to Bamboo 5.14**

**New API for VCS repositories**

We've rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

**Action required**

Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you're using any plugins that aren't officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian Marketplace).

Plugins that are particularly prone to incompatibilities and require special attention are those that deal with:

- automatic plan creation and management
- automatic plan branch creation and management
- repository configuration management

We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.

For details about the API changes, see [our developer documentation](#).

**Changes in requirements for table names of the external databases**

With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:

- **Upgrading to Bamboo 5.13 below**
- MySQL
- Bamboo 5.13 Release Notes

**See also**

- the general update steps section above.
- Bamboo 5.14 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our [developer documentation](#).

**Upgrading to Bamboo 5.13**

Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Database</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft SQL Server</td>
<td>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see <a href="#">Microsoft SQL Server</a>.</td>
</tr>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to <a href="#">Connecting Bamboo to an external database</a>. For MySQL specifically, this might affect all databases in the instance, see <a href="#">MySQL documentation</a>.</td>
</tr>
</tbody>
</table>
If the check fails

If the check fails and you can't correct your database configuration immediately, you can roll back to the previous installed version of Bamboo without changing anything in your database or home directory configuration.

See also:

- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.12

See:

- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.11

See:

- the general update steps section above.
- Bamboo 5.11 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.10

See:

- the general update steps section above.
- Bamboo 5.10 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.9

See also:

- the general update steps section above.
- the Bamboo 5.9 Release Notes.
- the Bamboo Supported platforms page.

Changes to Clover Plugin integration

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before). Automatic Clover integration will not happen when your Maven task contains the `install` or `deploy` commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the `install` or `deploy` Maven commands. If they do: either disable automatic Clover integration for those jobs, or change the phase to the `verify` command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover's coverage reports.

Upgrading to Bamboo 5.8

See also:

- the general update steps section above.
- the Bamboo 5.8 Release Notes.
- the Bamboo Supported platforms page.
If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

Hibernate dialect update

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the `bamboo.cfg.xml` file. The new dialects are:

```java
org.hibernate.dialect.PostgreSQLDialect
org.hibernate.dialect.HSQLDialect
org.hibernate.dialect.Oracle10gDialect
org.hibernate.dialect.MySQL5Dialect
com.atlassian.bamboo.hibernate.SQLServerIntlDialect
```

Upgrading to Bamboo 5.7

See also:

- the general update steps section above.
- the Bamboo 5.7 Release Notes.
- the Bamboo Supported platforms page.

Global deployment expiry

If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7. Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be removed. Most likely this is what you want but it’s important to be aware of this change.

Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release.

Read more about global expiry in Bamboo 5.7.

Upgrading to Bamboo 5.6

See also:

- the general update steps section above.
- the Bamboo 5.6 Release Notes.
- the Bamboo Supported platforms page.

Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated

Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on the Bitbucket Server page.

Update time

When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the `VARIABLE_CONTEXT` table. For a more precise calculation, assume that 10 minutes are needed to process 15 million records in that table.

Installer package on MAC OS X can not be opened due to code signing requirements

Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.6.

Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn’t from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see [BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X](https://jira.atlassian.com/browse/BAM-11742) for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available [here](https://jira.atlassian.com/browse/BAM-11742)
This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

**Upgrading to Bamboo 5.5**

- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket servers. If you have previously integrated Bamboo with Bitbucket Server, you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but OAuth is a better as it is an impersonating authentication type. For more information, see Configuring authentication for an application link.
- Git will use `--ancestry-path` when trying to extract changeset due to

<table>
<thead>
<tr>
<th>BAM-13760</th>
<th>Too many notifications for release -&gt; feature merge in Git plan branches</th>
</tr>
</thead>
</table>

  Since that command is available for Git 1.7.2 and above (see Release Notes), please update your native Git, if you have Git 1.7.1 installed (especially those who use RHEL 6 or CentOS).

See also:

- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

**Installer package on MAC OS X can not be opened due to code signing requirements**

**Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.5.**

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

<table>
<thead>
<tr>
<th>BAM-11742</th>
<th>Installer package is &quot;damaged and cannot be reopened&quot; on Mac OS X</th>
</tr>
</thead>
</table>

Please see for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

**Upgrading to Bamboo 5.4**

Note that Bamboo will run a full reindex after updating.

See also:

- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

**Installer package on MAC OS X can not be opened due to code signing requirements**

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see -

<table>
<thead>
<tr>
<th>BAM-11742</th>
<th>Installer package is &quot;damaged and cannot be reopened&quot; on Mac OS X</th>
</tr>
</thead>
</table>

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around solution available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

**Troubleshooting**

If you followed the documentation and you still have problems with the upgrade process:

- Check the How to Upgrade/Migrate Bamboo article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- You can also create a support ticket. To help us address the issue, attach the `atlassian-bamboo.log` file to the ticket.
Bamboo upgrade guide v6.3

You can upgrade Bamboo by installing a new version of Bamboo and setting it up with the configuration of the original Bamboo instance.

Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page. Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>1. Clone your Bamboo instance into the new location. 2. Perform the upgrade steps on the cloned Bamboo instance as described on this page. The cloned instance on the new server is referred to as original Bamboo instance.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.

We recommend that you test the Bamboo upgrade on a QA server before deploying to production.

If you are a Bamboo plugin developer, see our Bamboo API Changes by Version guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

Before you begin

Determine your upgrade path

When upgrading from very old versions of Bamboo you must follow this upgrade path:

- When upgrading from older versions of Bamboo, you must follow this upgrade path:

<table>
<thead>
<tr>
<th>OLDER VERSIONS</th>
<th>2.0.6</th>
<th>2.6.3</th>
<th>2.7.4</th>
<th>5.0–5.7</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.3</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- When upgrading from earlier than Bamboo 5.0, you must upgrade to any of Bamboo 5.0–5.14 before upgrading to Bamboo latest version:

<table>
<thead>
<tr>
<th>4.0–4.4</th>
<th>5.0–5.14</th>
<th>6.3</th>
</tr>
</thead>
</table>

- When upgrading from Bamboo 5.0 and later, you can upgrade directly to the latest version of Bamboo:

<table>
<thead>
<tr>
<th>5.0 +</th>
<th>6.3</th>
</tr>
</thead>
</table>

You do not need to downgrade before upgrading.

Before you begin

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

The installation path is referred to as `<bamboo-install>` and points to the directory into which you extracted the Bamboo package. It is different from `<bamboo-home>`, which points to the directory where Bamboo data is stored.
1. Export and back up the existing Bamboo data

**Export the Bamboo database**

There are two database backup scenarios, depending on whether you are using an embedded or external database.

<table>
<thead>
<tr>
<th>Embedded HSQL database</th>
<th>External database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an export .zip file for the original Bamboo instance. For more information, see Exporting data for backup.</td>
<td>Use native database tools to create a backup. For more information about external databases, see Connecting Bamboo to an external database.</td>
</tr>
<tr>
<td>The export may take a long time to complete and may require a large amount of disk space, depending on the number of builds and tests in your system.</td>
<td>HSQL is not recommended for production Bamboo instances.</td>
</tr>
</tbody>
</table>

**Stop Bamboo**

Stop the original Bamboo instance.

If you have Bamboo running as a Windows service, uninstall the service by using the UninstallService.bat executable that came with your Bamboo instance.

**Back up the Bamboo configuration**

When the original Bamboo instance is shut down, back up your `<bamboo-home>` directory, which contains the builds and configuration directories. You can compress it into a .zip file.

**Viewing Bamboo paths**

Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path:

```
Bamboo paths

Current running directory
Configuration path /Volumes/Pharoas/opt/dogfood/panda
Build path /Volumes/Pharoas/opt/dogfood/panda/home/xml-data/builds
Build working directory /Volumes/Pharoas/opt/dogfood/panda/home/xml-data/build-dir
Artifacts directory /Volumes/Pharoas/opt/dogfood/panda/home/artifacts
Bamboo home /Volumes/Pharoas/opt/dogfood/panda/home
Bamboo logs /Volumes/Pharoas/opt/dogfood/panda/home/logs/atlassian-bamboo.log
Temporary directory /Volumes/Pharoas/opt/dogfood/panda/tmpcam/temp
User home /Users/atlassian
```

For more information about these directories, see Important Directories and Files.

2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a `<bamboo-install>` directory that is different from the `<bamboo-install>` directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- Make sure that the original Bamboo instance is not running before you start the new installation.
- To prevent data loss during updates or reinstallation, the `<bamboo-home>` directory must be different from the `<bamboo-install>` directory.

The guidelines for the new Bamboo instance installation are the following:
Mac OS X

- The Mac installer deletes the previous version of Bamboo.
- Follow the Mac OS X install instructions.

Linux

- Delete your old `<Bamboo-install>` directory to remove any legacy files.
- Follow the Linux install instructions.

Windows

- The Windows installer deletes the previous version of Bamboo.
- Follow the Windows install instructions.
- Configure Bamboo to run as a service on Windows, using the `service.bat` executable.

3. Configure the new Bamboo instance

Set the home directory for the new Bamboo instance

Set the `<home-directory>` to use the `<home-directory>` of the original Bamboo instance:

1. Go to the new Bamboo instance `<bamboo-install>` directory. It is the directory where you installed Bamboo.
2. Open `atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`

   For Bamboo versions prior to 5.1, the file path is: `<bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties`

3. Set the `bamboo.home` variable to use the `<bamboo-home>` path of the original Bamboo instance.

Reconnect external user directories (optional)

If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance. For more information, see Integrating Crowd with Bamboo and Integrating Bamboo with LDAP.

Update any installed add-ons

If you installed any add-ons in addition to the pre-installed system add-ons:

- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

Automatic update of remote agents

For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.

For more information, see Bamboo remote agent installation guide.

Configure the context path

If you had a context path configured for the original Bamboo instance (http://hostname:[port]/context_path), you have to configure it for the new Bamboo instance. For more information, see Changing Bamboo’s root context path.

Check database access permission

Before you start the new Bamboo instance, make sure that it has the write access to the database, which is required to complete the upgrade tasks.

4. Start Bamboo

Start Bamboo

Once you have installed Bamboo and set the `bamboo.home` property, start the new Bamboo instance. The upgrade runs automatically.
You can check whether the upgrade was successful in the `atlassian-bamboo.log` file.

---

**Upgrading Bamboo may require reindexing.**

Depending on the number of existing builds and tests, the reindexing process may take a significant amount of time, during which Bamboo will not be available.

---

### Version-specific upgrade notes

The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

- **Upgrading to Bamboo 6.3...**

  **Change to the built-in database**

  Starting with Bamboo 6.3, the built-in HSQL database is replaced by H2. If you store any data in HSQL and want to keep it after the upgrade, you must export the data to XML and import back after you've installed the new version of Bamboo. See:

  - Exporting data for backup
  - Importing data from backup

  The H2 database is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.

  See also:

  - the general update steps section above.
  - Bamboo 6.3 Release Notes
  - the Bamboo Supported platforms page.

- **Upgrading to Bamboo 6.2...**

  See also:

  - the general update steps section above.
  - Bamboo 6.1 Release Notes
  - the Bamboo Supported platforms page.

  You might also want to check our Bamboo Specs reference documentation.

- **Upgrading to Bamboo 6.1...**

  See also:

  - the general update steps section above.
  - Bamboo 6.1 Release Notes
  - the Bamboo Supported platforms page.

  You might also want to check our Bamboo Specs reference documentation.

- **Upgrading to Bamboo 6.0...**

  **Microsoft JDBC driver**

  With Bamboo 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver.

  If database settings are configured directory in Bamboo, then during 6.0 upgrade it will attempt to update driver settings. In case of customized settings Bamboo instance administrator will be required to manually convert the settings.

  If database settings are configured in the container (Tomcat) and Bamboo uses datasource, automatic upgrade will not be possible and instance administration will be required to manually convert the settings.

  To learn more about this change, see [here](https://())

  **New library for setting up a JNDI resource for SMTP**

  Bamboo 6.0 is shipped with the `javax.mail-api-1.5.6.jar` library. This library needs to copied over to your `<Bamboo-install>/lib` folder when setting up a JNDI resource for SMTP. For more information, see [here](https://())

  **Changes to Git support**

  Starting from version 6.0, Bamboo changes support for Git to version 1.8.1.5 or later.
Upgrading to Bamboo 5.15...

Bamboo 5.15 contains upgrade tasks that can take extra time when moving from earlier versions of Bamboo. Keep this in mind when planning your upgrade outages.

Upgrading to Bamboo 5.14...

New API for VCS repositories

We’ve rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

Action required

Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you’re using any plugins that aren’t officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian Marketplace).

We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.

For details about the API changes, see our developer documentation.

Changes in requirements for table names of the external databases

With Bamboo 5.14, we’re dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:

- Upgrading to Bamboo 5.13 below
- MySQL
- Bamboo 5.13 Release Notes

See also

- the general update steps section above.
- Bamboo 5.14 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.13...

Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Database</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft SQL Server</td>
<td>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see Microsoft SQL Server.</td>
</tr>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to Connecting Bamboo to an external database. For MySQL specifically, this might affect all databases in the instance, see MySQL documentation.</td>
</tr>
</tbody>
</table>

If the check fails

If the check fails and you can’t correct your database configuration immediately, you can roll back to the previous installed version of Bamboo without changing anything in your database or home directory configuration.

See also:

- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.12...

See:

- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.11...

See:

- the general update steps section above.
Bamboo 5.11 Release Notes.
the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.10...

**Upgrading to Bamboo 5.10**

See:

- the general update steps section above.
- Bamboo 5.10 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.9...

**Changes to Clover Plugin integration**

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before). Automatic Clover integration will not happen when your Maven task contains the `install` or `deploy` commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the `install` or `deploy` Maven commands. If they do: either disable automatic Clover integration for those jobs, or change the phase to the `verify` command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover's coverage reports.

See also:

- the general update steps section above.
- the Bamboo 5.9 Release Notes.
- the Bamboo Supported platforms page.

Upgrading to Bamboo 5.8...

**Hibernate dialect update**

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the `bamboo.cfg.xml` file. The new dialects are:

```
org.hibernate.dialect.PostgreSQLDialect
org.hibernate.dialect.HSQLDialect
org.hibernate.dialect.Oracle10gDialect
org.hibernate.dialect.MySQL5Dialect
com.atlassian.bamboo.hibernate.SQLServerIntlDialect
```

See also:

- the general update steps section above.
- the Bamboo 5.8 Release Notes.
- the Bamboo Supported platforms page.

If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

Upgrading to Bamboo 5.7...

**Global deployment expiry**

If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7.

Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be
removed. Most likely this is what you want but it's important to be aware of this change. Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release. Read more about global expiry in Bamboo 5.7.

See also:
- the general update steps section above.
- the Bamboo 5.7 Release Notes.
- the Bamboo Supported platforms page.

Upgrading to Bamboo 5.6...

Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated

Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on Bitbucket Server.

Update time

When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the VARIABLE_CONTEXT table. For a more precise calculation, assume that 10 minutes are needed to process 15 million records in that table.

Installer package on MAC OS X can not be opened due to code signing requirements

Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.6.

Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see BAM-11742 : Installer package is "damaged and cannot be reopened" on Mac OS X for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available here.

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

See also:
- the general update steps section above.
- the Bamboo 5.6 Release Notes.
- the Bamboo Supported platforms page.

Upgrading to Bamboo 5.5...

- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket servers. If you have previously integrated Bamboo with Bitbucket Server, you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but OAuth is a better as it is an impersonating authentication type. For more information, see Configuring authentication for an application link.
- Git will use --ancestry-path when trying to extract changeset due to

BAM-13760 : Too many notifications for release -> feature merge in Git plan branches. Since that command is available for Git 1.7.2 and above (see Release Notes), please update your native Git, if you have Git 1.7.1 installed (especially those who use RHEL 6 or CentOS).

See also:
- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

Upgrading to Bamboo 5.4...

Note that Bamboo will run a full reindex after updating.

Installer package on MAC OS X can not be opened due to code signing requirements

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than
being blocked by developer ID.

Please see

BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X [RESOLVED] for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around solution available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

See also:
- the general update steps section above.
- the Bamboo 5.4 release notes.
- the Bamboo Supported platforms page.

Troubleshooting

If you followed the documentation and you still have problems with the upgrade process:

- Check the How to Upgrade/Migrate Bamboo article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- You can also create a support ticket. To help us address the issue, attach the atlassian-bamboo.log file to the ticket.

.Bamboo upgrade guide v6.4

You can upgrade Bamboo by installing a new version of Bamboo and setting it up with the configuration of the original Bamboo instance.

Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page.</td>
<td>1. Clone your Bamboo instance into the new location.</td>
</tr>
<tr>
<td>Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>2. Perform the upgrade steps on the cloned Bamboo instance as described on this page.</td>
</tr>
<tr>
<td></td>
<td>The cloned instance on the new server is referred to as original Bamboo instance.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.

We recommend that you test the Bamboo upgrade on a QA server before deploying to production.

If you are a Bamboo plugin developer, see our Bamboo API Changes by Version guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

Before you begin

Determine your upgrade path

Upgrade path

- When upgrading from very old versions of Bamboo you must follow this upgrade path:

<table>
<thead>
<tr>
<th>OLDER VERSIONS</th>
<th>2.0.6</th>
<th>2.6.3</th>
<th>2.7.4</th>
<th>5.0–5.7</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- When upgrading from earlier than Bamboo 5.0, you must upgrade to any of Bamboo 5.0–5.14 before upgrading to
Before you begin

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

The installation path is referred to as `<bamboo-install>` and points to the directory into which you extracted the Bamboo package. It is different from `<bamboo-home>`, which points to the directory where Bamboo data is stored.

1. Export and back up the existing Bamboo data

Export the Bamboo database

There are two database backup scenarios, depending on whether you are using an embedded or external database.

<table>
<thead>
<tr>
<th>Embedded HSQL database</th>
<th>External database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an export .zip file for the original Bamboo instance. For more information, see Exporting data for backup.</td>
<td>Use native database tools to create a backup. For more information about external databases, see Connecting Bamboo to an external database.</td>
</tr>
<tr>
<td>The export may take a long time to complete and may require a large amount of disk space, depending on the number of builds and tests in your system.</td>
<td></td>
</tr>
<tr>
<td>HSQl is not recommended for production Bamboo instances.</td>
<td></td>
</tr>
</tbody>
</table>

Stop Bamboo

Stop the original Bamboo instance.

If you have Bamboo running as a Windows service, uninstall the service by using the UninstallService.bat executable that came with your Bamboo instance.

Back up the Bamboo configuration

When the original Bamboo instance is shut down, back up your `<bamboo-home >` directory, which contains the builds and configuration directories. You can compress it into a .zip file.

Viewing Bamboo paths

Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path:
2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a `<bamboo-install>` directory that is different from the `<bamboo-install>` directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- Make sure that the original Bamboo instance is not running before you start the new installation.
- To prevent data loss during updates or reinstallation, the `<bamboo-home>` directory must be different from the `<bamboo-install>` directory.

The guidelines for the new Bamboo instance installation are the following:

**Mac OS X**
- The Mac installer deletes the previous version of Bamboo.
- Follow the [Mac OS X install instructions](#).

**Linux**
- Delete your old `<Bamboo-install>` directory to remove any legacy files.
- Follow the [Linux install instructions](#).

**Windows**
- The Windows installer deletes the previous version of Bamboo.
- Follow the [Windows install instructions](#).
- Configure Bamboo to run as a service on Windows, using the `service.bat` executable.

3. Configure the new Bamboo instance

Set the home directory for the new Bamboo instance

Set the `<home-directory>` to use the `<home-directory>` of the original Bamboo instance:

1. Go to the new Bamboo instance `<bamboo-install>` directory. It is the directory where you installed Bamboo.
2. Open `atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`

For Bamboo versions prior to 5.1, the file path is: `<bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties`

3. Set the `bamboo.home` variable to use the `<bamboo-home>` path of the original Bamboo instance.

Reconnect external user directories (optional)

<table>
<thead>
<tr>
<th>Bamboo paths</th>
</tr>
</thead>
<tbody>
<tr>
<td>Current running directory</td>
</tr>
<tr>
<td>Configuration path</td>
</tr>
<tr>
<td>Build path</td>
</tr>
<tr>
<td>Build working</td>
</tr>
<tr>
<td>Artifacts directory</td>
</tr>
<tr>
<td>Bamboo home</td>
</tr>
<tr>
<td>Bamboo logs</td>
</tr>
<tr>
<td>Temporary directory</td>
</tr>
<tr>
<td>User home</td>
</tr>
</tbody>
</table>
If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance. For more information, see Integrating Crowd with Bamboo and Integrating Bamboo with LDAP.

**Update any installed add-ons**

If you installed any add-ons in addition to the pre-installed system add-ons:

- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

**Automatic update of remote agents**

For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.

For more information, see Bamboo remote agent installation guide.

**Configure the context path**

If you had a context path configured for the original Bamboo instance (http://hostname:[port]/context_path), you have to configure it for the new Bamboo instance. For more information, see Changing Bamboo's root context path.

**Check database access permission**

Before you start the new Bamboo instance, make sure that it has the write access to the database, which is required to complete the upgrade tasks.

4. Start Bamboo

Start Bamboo

Once you have installed Bamboo and set the bamboo.home property, start the new Bamboo instance. The upgrade runs automatically.

You can check whether the upgrade was successful in the atlassian-bamboo.log file.

Upgrading Bamboo may require reindexing.

Depending on the number of existing builds and tests, the reindexing process may take a significant amount of time, during which Bamboo will not be available.

**Version-specific upgrade notes**

The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

- **Upgrading to Bamboo 6.4...**
  
  Hung Build Killer added to the add-on blacklist

  Bamboo 6.4 is shipped with a native mechanism for monitoring builds. For that reason, the Hung Build Killer plugins becomes deprecated. See Add-on blacklist.

  See also:
  - the general update steps section above.
  - Bamboo 6.4 Release Notes
  - the Bamboo Supported platforms page.

- **Upgrading to Bamboo 6.3...**

  **Change to the built-in database**

  Starting with Bamboo 6.3, the built-in HSQL database is replaced by H2. If you store any data in HSQL and want to keep it after the upgrade, you must export the data to XML and import back after you’ve installed the new version of Bamboo. See:
  - Exporting data for backup
Importing data from backup

The H2 database is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.

See also:
- the general update steps section above.
- Bamboo 6.3 Release Notes
- the Bamboo Supported platforms page.

Upgrading to Bamboo 6.2...

See also:
- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

Upgrading to Bamboo 6.1...

See also:
- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

Upgrading to Bamboo 6.0...

Microsoft JDBC driver

With Bamboo 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver.

If database settings are configured directory in Bamboo, then during 6.0 upgrade it will attempt to update driver settings. In case of customized settings Bamboo instance administrator will be required to manually convert the settings.

To learn more about this change, see here.

New library for setting up a JNDI resource for SMTP

Bamboo 6.0 is shipped with the javax.mail-api-1.5.6.jar library. This library needs to copied over to your <Bamboo-install>/lib folder when setting up a JNDI resource for SMTP. For more information, see here.

Changes to Git support

Starting from version 6.0, Bamboo changes support for Git to version 1.8.1.5 or later.

Upgrading to Bamboo 5.15...

Bamboo 5.15 contains upgrade tasks that can take extra time when moving from earlier versions of Bamboo. Keep this in mind when planning your upgrade outages.

Upgrading to Bamboo 5.14...

New API for VCS repositories

We've rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

Action required

Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you're using any plugins that aren't officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian Marketplace).

We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.

For details about the API changes, see our developer documentation.

Changes in requirements for table names of the external databases

With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:

- Upgrading to Bamboo 5.13 below
Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Check Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft SQL Server</td>
<td>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see Microsoft SQL Server.</td>
</tr>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to Connecting Bamboo to an external database. For MySQL specifically, this might affect all databases in the instance, see MySQL documentation.</td>
</tr>
</tbody>
</table>

If the check fails

If the check fails and you can't correct your database configuration immediately, you can roll back to the previous installed version of Bamboo without changing anything in your database or home directory configuration.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.10

See:

- the general update steps section above.
- Bamboo 5.10 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.9...
Changes to Clover Plugin integration

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before). Automatic Clover integration will not happen when your Maven task contains the `install` or `deploy` commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the `install` or `deploy` Maven commands. If they do: either disable automatic Clover integration for those jobs, or change the phase to the `verify` command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover's coverage reports.

See also:
- the general update steps section above.
- the Bamboo 5.9 Release Notes.
- the Bamboo Supported platforms page.

Upgrading to Bamboo 5.8...

Hibernate dialect update

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the `bamboo.cfg.xml` file. The new dialects are:

```
org.hibernate.dialect.PostgreSQLDialect
org.hibernate.dialect.HSQLDialect
org.hibernate.dialect.Oracle10gDialect
org.hibernate.dialect.MySQL5Dialect
com.atlassian.bamboo.hibernate.SQLServerIntlDialect
```

See also:
- the general update steps section above.
- the Bamboo 5.8 Release Notes.
- the Bamboo Supported platforms page.

If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

Upgrading to Bamboo 5.7...

Global deployment expiry

If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7. Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be removed. Most likely this is what you want but it's important to be aware of this change.

Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release. Read more about global expiry in Bamboo 5.7.

See also:
- the general update steps section above.
- the Bamboo 5.7 Release Notes.
- the Bamboo Supported platforms page.

Upgrading to Bamboo 5.6...

Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated

Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on Bitbucket Server.

Update time

When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the VARIABLE_CONTEXT table. For a more precise calculation, assume that you want 10 minutes are needed to process 15 million records in that table.

Installer package on MAC OS X can not be opened due to code signing requirements

Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.6.
Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see [BAM-11742](https://jira.atlassian.com/browse/BAM-11742) - Installer package is "damaged and cannot be reopened" on Mac OS X for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available here.

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

See also:

- the general update steps section above.
- the Bamboo 5.6 Release Notes.
- the Bamboo Supported platforms page.

**Upgrade to Bamboo 5.5...**

- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket servers. If you have previously [integrated Bamboo with Bitbucket Server](https://docs.atlassian.com/bitbucket-server), you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but OAuth is a better as it is an impersonating authentication type. For more information, see [Configuring authentication for an application link](https://docs.atlassian.com/bamboo/oauth#oauth1).
- Git will use `--ancestry-path` when trying to extract changeset due to

Please see [BAM-13760](https://jira.atlassian.com/browse/BAM-13760) - Too many notifications for release -> feature merge in Git plan branches for more information.

Since that command is available for Git 1.7.2 and above (see [Release Notes](https://docs.atlassian.com/Create-Bamboo-5.5.13760)), please update your native Git, if you have Git 1.7.1 installed (especially those who use RHEL 6 or CentOS).

See also:

- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

**Upgrade to Bamboo 5.4...**

Note that Bamboo will run a full reindex after updating.

Installer package on MAC OS X can not be opened due to code signing requirements

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see

[BAM-11742](https://jira.atlassian.com/browse/BAM-11742) - Installer package is "damaged and cannot be reopened" on Mac OS X for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

See also:

- the general update steps section above.
- the Bamboo 5.4 release notes.
- the Bamboo Supported platforms page.

**Troubleshooting**

If you followed the documentation and you still have problems with the upgrade process:

- Check the [How to Upgrade/Migrate Bamboo](https://docs.atlassian.com/bamboo#how-to-upgrade-migrate-bamboo) article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- Ask questions at [https://answers.atlassian.com](https://answers.atlassian.com).
- You can also create a [support ticket](https://jira.atlassian.com/). To help us address the issue, attach the [atlassian-bamboo.log](https://jira.atlassian.com/) file to the ticket.
Bamboo upgrade guide v6.5

You can upgrade Bamboo by installing a new version of Bamboo and setting it up with the configuration of the original Bamboo instance.

Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page. Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>1. Clone your Bamboo instance into the new location. 2. Perform the upgrade steps on the cloned Bamboo instance as described on this page. The cloned instance on the new server is referred to as original Bamboo instance.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.

We recommend that you test the Bamboo upgrade on a QA server before deploying to production.

If you are a Bamboo plugin developer, see our Bamboo API Changes by Version guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

Before you begin

Determine your upgrade path

- When upgrading from very old versions of Bamboo you must follow this upgrade path:

<table>
<thead>
<tr>
<th>OLDER VERSIONS</th>
<th>2.0.6</th>
<th>2.6.3</th>
<th>2.7.4</th>
<th>5.0–5.7</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.5</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- When upgrading from earlier than Bamboo 5.0, you must upgrade to any of Bamboo 5.0–5.14 before upgrading to Bamboo latest version:

<table>
<thead>
<tr>
<th>4.0–4.4</th>
<th>5.0–5.14</th>
<th>6.5</th>
</tr>
</thead>
</table>

- When upgrading from Bamboo 5.0 and later, you can upgrade directly to the latest version of Bamboo:

<table>
<thead>
<tr>
<th>5.0+</th>
<th>6.5</th>
</tr>
</thead>
</table>

You do not need to downgrade before upgrading.

Before you begin

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

The installation path is referred to as `<bamboo-install>` and points to the directory into which you extracted the Bamboo package. It is different from `<bamboo-home>`, which points to the directory where Bamboo data is stored.
1. Export and back up the existing Bamboo data

**Export the Bamboo database**

There are two database backup scenarios, depending on whether you are using an embedded or external database.

<table>
<thead>
<tr>
<th>Embedded HSQL database</th>
<th>External database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an export .zip file for the original Bamboo instance. For more information, see Exporting data for backup.</td>
<td>Use native database tools to create a backup. For more information about external databases, see Connecting Bamboo to an external database.</td>
</tr>
<tr>
<td>The export may take a long time to complete and may require a large amount of disk space, depending on the number of builds and tests in your system.</td>
<td></td>
</tr>
<tr>
<td><strong>HSQL is not recommended</strong> for production Bamboo instances.</td>
<td></td>
</tr>
</tbody>
</table>

**Stop Bamboo**

Stop the original Bamboo instance.

If you have Bamboo running as a Windows service, uninstall the service by using the UninstallService.bat executable that came with your Bamboo instance.

**Back up the Bamboo configuration**

When the original Bamboo instance is shut down, back up your <bamboo-home > directory, which contains the builds and configuration directories. You can compress it into a .zip file.

**Viewing Bamboo paths**

Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path:

- Bamboo paths
  - Current running directory
  - Configuration path
  - Build path
  - Build working directory
  - Artifacts directory
  - Bamboo home
  - Bamboo logs
  - Temporary directory
  - User home

For more information about these directories, see Important Directories and Files.

2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a <bamboo-install> directory that is different from the <bamboo-install> directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- Make sure that the original Bamboo instance is not running before you start the new installation.
- To prevent data loss during updates or reinstallation, the <bamboo-home > directory must be different from the <bamboo-install> directory.

The guidelines for the new Bamboo instance installation are the following:
1. Mac OS X
   - The Mac installer deletes the previous version of Bamboo.
   - Follow the Mac OS X install instructions.

2. Linux
   - Delete your old `<Bamboo-install>` directory to remove any legacy files.
   - Follow the Linux install instructions.

3. Windows
   - The Windows installer deletes the previous version of Bamboo.
   - Follow the Windows install instructions.
   - Configure Bamboo to run as a service on Windows, using the `service.bat` executable.

3. Configure the new Bamboo instance

Set the home directory for the new Bamboo instance

Set the `<home-directory>` to use the `<home-directory>` of the original Bamboo instance:

1. Go to the new Bamboo instance `<bamboo-install>` directory. It is the directory where you installed Bamboo.
2. Open `atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`

   For Bamboo versions prior to 5.1, the file path is: `<bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties`

3. Set the `bamboo.home` variable to use the `<bamboo-home>` path of the original Bamboo instance.

Reconnect external user directories (optional)

If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance.

For more information, see [Integrating Crowd with Bamboo](Integrating Crowd with Bamboo) and [Integrating Bamboo with LDAP](Integrating Bamboo with LDAP).

Update any installed add-ons

If you installed any add-ons in addition to the pre-installed system add-ons:

- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

Automatic update of remote agents

For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.

For more information, see [Bamboo remote agent installation guide](Bamboo remote agent installation guide).

Migrate your existing Bamboo configurations over to your new Bamboo installation

If you have modified properties in configuration files of your existing Bamboo installation, make the same modifications in your new Bamboo installation. However, because the properties in the configuration files may have changed between versions, you cannot simply copy the configuration files from your existing installation and replace the equivalent files in the new installation.

For each file you have modified in your existing Bamboo installation, you need to manually edit each equivalent file in your new Bamboo installation and re-apply your modifications.

The table below lists the most commonly modified files and their locations within your Bamboo Installation Directory:

<table>
<thead>
<tr>
<th>File</th>
<th>Location in Bamboo installation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>setenv.bat</code> (Windows) or</td>
<td><code>bin</code></td>
<td>Configuring your system</td>
</tr>
<tr>
<td><code>setenv.sh</code> (Linux)</td>
<td></td>
<td>properties</td>
</tr>
</tbody>
</table>

For Bamboo versions prior to 5.1, the file path is: `<bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties`
Check database access permission

Before you start the new Bamboo instance, make sure that it has the write access to the database, which is required to complete the upgrade tasks.

4. Start Bamboo

Start Bamboo

Once you have installed Bamboo and set the bamboo.home property, start the new Bamboo instance. The upgrade runs automatically.

You can check whether the upgrade was successful in the atlassian-bamboo.log file.

Upgrading Bamboo may require reindexing.

Depending on the number of existing builds and tests, the reindexing process may take a significant amount of time, during which Bamboo will not be available.

Version-specific upgrade notes

The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

- **Upgrading to Bamboo 6.5...**
  See:
  - the general update steps section above.
  - Bamboo 6.5 Release Notes
  - the Bamboo Supported platforms page.

- **Upgrading to Bamboo 6.4...**

  Hung Build Killer added to the add-on blacklist

  Bamboo 6.4 is shipped with a native mechanism for monitoring builds. For that reason, the Hung Build Killer plugins becomes deprecated. See Add-on blacklist.

  See also:
  - the general update steps section above.
  - Bamboo 6.4 Release Notes
  - the Bamboo Supported platforms page.

- **Upgrading to Bamboo 6.3...**

  Change to the built-in database

  Starting with Bamboo 6.3, the built-in HSQL database is replaced by H2. If you store any data in HSQL and want to keep it after the upgrade, you must export the data to XML and import back after you've installed the new version of Bamboo. See:
  - Exporting data for backup
  - Importing data from backup

  The H2 database is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.

  See also:
  - the general update steps section above.
  - Bamboo 6.3 Release Notes
  - the Bamboo Supported platforms page.
Upgrading to Bamboo 6.2...

See also:

- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

Upgrading to Bamboo 6.1...

See also:

- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

Upgrading to Bamboo 6.0...

Microsoft JDBC driver

With Bamboo 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver.

If database settings are configured directory in Bamboo, then during 6.0 upgrade it will attempt to update driver settings. In case of customized settings Bamboo instance administrator will be required to manually convert the settings.

To learn more about this change, see here.

New library for setting up a JNDI resource for SMTP

Bamboo 6.0 is shipped with the `javax.mail-api-1.5.6.jar` library. This library needs to copied over to your `<Bamboo-install>/lib` folder when setting up a JNDI resource for SMTP. For more information, see here.

Changes to Git support

Starting from version 6.0, Bamboo changes support for Git to version 1.8.1.5 or later.

Upgrading to Bamboo 5.15...

Bamboo 5.15 contains upgrade tasks that can take extra time when moving from earlier versions of Bamboo. Keep this in mind when planning your upgrade outages.

Upgrading to Bamboo 5.14...

New API for VCS repositories

We've rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

Action required

Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you're using any plugins that aren't officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian Marketplace).

We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.

For details about the API changes, see our developer documentation.

Changes in requirements for table names of the external databases

With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:

- Upgrading to Bamboo 5.13 below
- MySQL
- Bamboo 5.13 Release Notes

See also

- the general update steps section above.
- Bamboo 5.14 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.
Upgrading to Bamboo 5.13...

Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Database</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft SQL Server</td>
<td>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see Microsoft SQL Server.</td>
</tr>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to Connecting Bamboo to an external database. For MySQL specifically, this might affect all databases in the instance, see MySQL documentation.</td>
</tr>
</tbody>
</table>

If the check fails

If the check fails and you can't correct your database configuration immediately, you can roll back to the previous installed version of Bamboo without changing anything in your database or home directory configuration.

See also:
- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.12...

See:
- the general update steps section above.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.11...

See:
- the general update steps section above.
- Bamboo 5.11 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.10...

Upgrading to Bamboo 5.10

See:
- the general update steps section above.
- Bamboo 5.10 Release Notes.
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.9...

Changes to Clover Plugin integration

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before). Automatic Clover integration will not happen when your Maven task contains the `install` or `deploy` commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the `install` or `deploy` Maven commands. If they do, either disable automatic Clover integration for those jobs, or change the phase to the `verify` command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover's coverage reports.
See also:
- the general update steps section above.
- the Bamboo 5.9 Release Notes.
- the Bamboo Supported platforms page.

**Upgrading to Bamboo 5.8...**

Hibernate dialect update

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the `bamboo.cfg.xml` file. The new dialects are:

```
org.hibernate.dialect.PostgreSQLDialect  
org.hibernate.dialect.HSQLDialect    
org.hibernate.dialect.Oracle10gDialect  
org.hibernate.dialect.MySQL5Dialect   
com.atlassian.bamboo.hibernate.SQLServerIntlDialect
```

See also:
- the general update steps section above.
- the Bamboo 5.8 Release Notes.
- the Bamboo Supported platforms page.

If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

**Upgrading to Bamboo 5.7...**

Global deployment expiry

If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7. Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be removed. Most likely this is what you want but it's important to be aware of this change.

Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release.

Read more about global expiry in Bamboo 5.7.

See also:
- the general update steps section above.
- the Bamboo 5.7 Release Notes.
- the Bamboo Supported platforms page.

**Upgrading to Bamboo 5.6...**

Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated

Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on Bitbucket Server.

Update time

When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the VARIABLE_CONTEXT table. For a more precise calculation, assume that 10 minutes are needed to process 15 million records in that table.

Installer package on MAC OS X can not be opened due to code signing requirements

Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.6.

Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see [BAM-11742](https://jira.atlassian.com/browse/BAM-11742) - Installer package is "damaged and cannot be reopened" on Mac OS X for more information.
1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available here.

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

See also:
- the general update steps section above.
- the Bamboo 5.6 Release Notes.
- the Bamboo Supported platforms page.

**Upgrading to Bamboo 5.5...**
- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket servers. If you have previously integrated Bamboo with Bitbucket Server, you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but OAuth is a better as it is an impersonating authentication type. For more information, see Configuring authentication for an application link.
- Git will use --ancestry-path when trying to extract changeset due to

  ![BAM-13760 - Too many notifications for release -> feature merge in Git plan branches](RESOLVED). Since that
  command is available for Git 1.7.2 and above (see Release Notes), please update your native Git, if you have Git 1.7.1
  installed (especially those who use RHEL 6 or CentOS).

See also:
- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

**Upgrading to Bamboo 5.4...**
Note that Bamboo will run a full reindex after updating.

Installer package on MAC OS X can not be opened due to code signing requirements

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see

![BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X](RESOLVED) for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around solution available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

See also:
- the general update steps section above.
- the Bamboo 5.4 release notes.
- the Bamboo Supported platforms page.

**Troubleshooting**
If you followed the documentation and you still have problems with the upgrade process:

- Check the How to Upgrade/Migrate Bamboo article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- You can also create a support ticket. To help us address the issue, attach the atlassian-bamboo.log file to the ticket.

**Bamboo upgrade guide v6.6**
You can upgrade Bamboo by installing a new version of Bamboo
and setting it up with the configuration of the original Bamboo instance.
Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page. Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>1. Clone your Bamboo instance into the new location. 2. Perform the upgrade steps on the cloned Bamboo instance as described on this page. The cloned instance on the new server is referred to as original Bamboo instance.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.

We recommend that you test the Bamboo upgrade on a QA server before deploying to production.

If you are a Bamboo plugin developer, see our Bamboo API Changes by Version guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

Before you begin

**Determine your upgrade path**

- **Upgrade path**
  - When upgrading from very old versions of Bamboo, follow this upgrade path:
    - OLDER VERSIONS 6.5 LATEST
    - 2.0.6
    - 2.6.3
    - 2.7.4
    - 5.0–5.7
  - When upgrading from earlier than Bamboo 5.0, follow this upgrade path:
    - 4.0–4.4
    - 5.14 LATEST
  - When upgrading from Bamboo 5.0 and later, follow this upgrade path:
    - 5.0-5.13
    - 5.14 LATEST
  - When upgrading from Bamboo 5.14 and later, follow this upgrade path:
    - 5.14+
    - LATEST

**Before you begin**

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

The installation path is referred to as `<bamboo-install>` and points to the directory into which you extracted the Bamboo...
1. Export and back up the existing Bamboo data

**Export the Bamboo database**

There are two database backup scenarios, depending on whether you are using an embedded or external database.

<table>
<thead>
<tr>
<th>Embedded HSQL database</th>
<th>External database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an export .zip file for the original Bamboo instance. For more information, see Exporting data for backup.</td>
<td>Use native database tools to create a backup. For more information about external databases, see Connecting Bamboo to an external database.</td>
</tr>
</tbody>
</table>

The export may take a long time to complete and may require a large amount of disk space, depending on the number of builds and tests in your system.

**Stop Bamboo**

Stop the original Bamboo instance.

If you have Bamboo running as a Windows service, uninstall the service by using the UninstallService.bat executable that came with your Bamboo instance.

**Back up the Bamboo configuration**

When the original Bamboo instance is shut down, back up your <bamboo-home> directory, which contains the builds and configuration directories. You can compress it into a .zip file.

**Viewing Bamboo paths**

Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path:

```
Bamboo paths

Current running /Volumes/Parhisl/opt/dogfood/panda
directory
Configuration path /Volumes/Parhisl/opt/dogfood/panda/home/xml-data/configuration
Build path /Volumes/Parhisl/opt/dogfood/panda/home/xml-data/builds
Build working /Volumes/Parhisl/opt/dogfood/panda/home/xml-data/build-dir
directory
Artifacts directory /Volumes/Parhisl/opt/dogfood/panda/home/artifacts
Bamboo home /Volumes/Parhisl/opt/dogfood/panda/home
Bamboo logs /Volumes/Parhisl/opt/dogfood/panda/home/logs/atlassian-bamboo.log
Temporary directory /Volumes/Parhisl/opt/dogfood/panda/atmcat/term
User home /Users/atlassian
```

For more information about these directories, see Important Directories and Files.

2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a <bamboo-install> directory that is different from the <bamboo-home> directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- Make sure that the original Bamboo instance is not running before you start the new installation.
- To prevent data loss during updates or reinstallation, the <bamboo-home> directory must be different from the <
1. The guidelines for the new Bamboo instance installation are the following:

Mac OS X
- The Mac installer deletes the previous version of Bamboo.
- Follow the Mac OS X install instructions.

Linux
- Delete your old <Bamboo-install> directory to remove any legacy files.
- Follow the Linux install instructions.

Windows
- The Windows installer deletes the previous version of Bamboo.
- Follow the Windows install instructions.
- Configure Bamboo to run as a service on Windows, using the service.bat executable.

3. Configure the new Bamboo instance

Set the home directory for the new Bamboo instance

Set the <home-directory> to use the <home-directory> of the original Bamboo instance:

1. Go to the new Bamboo instance <bamboo-install> directory. It is the directory where you installed Bamboo.
2. Open atlassian-bamboo/WEB-INF/classes/bamboo-init.properties

For Bamboo versions prior to 5.1, the file path is: <bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties

3. Set the bamboo.home variable to use the <bamboo-home> path of the original Bamboo instance.

Reconnect external user directories (optional)
If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance.
For more information, see Integrating Crowd with Bamboo and Integrating Bamboo with LDAP.

Update any installed add-ons
If you installed any add-ons in addition to the pre-installed system add-ons:
- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

Automatic update of remote agents
For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.
For more information, see Bamboo remote agent installation guide.

Migrate your existing Bamboo configurations over to your new Bamboo installation
If you have modified properties in configuration files of your existing Bamboo installation, make the same modifications in your new Bamboo installation. However, because the properties in the configuration files may have changed between versions, you cannot simply copy the configuration files from your existing installation and replace the equivalent files in the new installation.
For each file you have modified in your existing Bamboo installation, you need to manually edit each equivalent file in your new Bamboo installation and re-apply your modifications.

The table below lists the most commonly modified files and their locations within your Bamboo Installation Directory:

<table>
<thead>
<tr>
<th>File</th>
<th>Location in Bamboo installation</th>
<th>Description</th>
</tr>
</thead>
</table>

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
setenv.bat (Windows) or setenv.sh (Linux)  bin  Configuring your system properties

seraph-config.xml  atlassian-bamboo/WEB-INF/classes  Modified if you had integrated Bamboo with Crowd

server.xml  conf  Modified in the following situations:
• If you had previously changed Bamboo’s root context path.
• If you had previously secured Bamboo with Tomcat using SSL or proxy server.

Check database access permission
Before you start the new Bamboo instance, make sure that it has the write access to the database, which is required to complete the upgrade tasks.

4. Start Bamboo

Start Bamboo
Once you have installed Bamboo and set the bamboo.home property, start the new Bamboo instance. The upgrade runs automatically.
You can check whether the upgrade was successful in the atlassian-bamboo.log file.

Upgrading Bamboo may require reindexing.
Depending on the number of existing builds and tests, the reindexing process may take a significant amount of time, during which Bamboo will not be available.

Version-specific upgrade notes
The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

имер Upgrading to Bamboo 6.6...

New upgrade threshold
We’ve made some changes to the possible Bamboo upgrade paths. To figure our the best way to upgrade your Bamboo to the latest version, see the upgrade path.

Heroku plugin not supported
Heroku’s API changes rendered the Heroku plugin for Bamboo non-functional and we no longer deploy it with Bamboo. Check this Dev Center article on WAR Deployment for recommended alternatives.

- the Bamboo Supported platforms page.

**Upgrading to Bamboo 6.2...**

See also:

- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

**Upgrading to Bamboo 6.1...**

See also:

- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

**Upgrading to Bamboo 6.0...**

**Microsoft JDBC driver**

With Bamboo 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver.

If database settings are configured directory in Bamboo, then during 6.0 upgrade it will attempt to update driver settings. In case of customized settings Bamboo instance administrator will be required to manually convert the settings.

If database settings are configured in the container (Tomcat) and Bamboo uses datasource, automatic upgrade will not be possible and instance administration will be required to manually convert the settings.

To learn more about this change, see here.

**New library for setting up a JNDI resource for SMTP**

Bamboo 6.0 is shipped with the javax.mail-api-1.5.6.jar library. This library needs to copied over to your <Bamboo-install>/lib folder when setting up a JNDI resource for SMTP. For more information, see here.

**Changes to Git support**

Starting from version 6.0, Bamboo changes support for Git to version 1.8.1.5 or later.

**Upgrading to Bamboo 5.15...**

Bamboo 5.15 contains upgrade tasks that can take extra time when moving from earlier versions of Bamboo. Keep this in mind when planning your upgrade outages.

**Upgrading to Bamboo 5.14...**

**New API for VCS repositories**

We've rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

**Action required**

Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you're using any plugins that aren't officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian.
Marketplace).
We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.
For details about the API changes, see our developer documentation.

Changes in requirements for table names of the external databases

With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:

- Upgrading to Bamboo 5.13 below
- MySQL
- Bamboo 5.13 Release Notes

See also

- the general update steps section above.
- Bamboo 5.14 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Upgrading to Bamboo 5.13...

Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft SQL Server</td>
<td>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see <a href="#">Microsoft SQL Server</a>.</td>
</tr>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to <a href="#">Connecting Bamboo to an external database</a>. For MySQL specifically, this might affect all databases in the instance, see <a href="#">MySQL documentation</a>.</td>
</tr>
</tbody>
</table>

If the check fails

If the check fails and you can't correct your database configuration immediately, you can roll back to the previous installed version of Bamboo without changing anything in your database or home directory configuration.

- the Bamboo Supported platforms page.

You might also want to check our developer documentation.

Remember that remote agents must be restarted after the upgrade.

Upgrading to Bamboo 5.10...

Upgrading to Bamboo 5.10

See:
Upgrading to Bamboo 5.9...

Changes to Clover Plugin integration

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before). Automatic Clover integration will not happen when your Maven task contains the `install` or `deploy` commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the `install` or `deploy Maven commands. If they do: either disable automatic Clover integration for those jobs, or change the phase to the `verify` command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover's coverage reports.

See also:
- the general update steps section above.
- the Bamboo 5.9 Release Notes.
- the Bamboo Supported platforms page.

Upgrading to Bamboo 5.8...

Hibernate dialect update

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the `bamboo.cfg.xml` file. The new dialects are:

```
org.hibernate.dialect.PostgreSQLDialect
org.hibernate.dialect.HSQLDialect
org.hibernate.dialect.Oracle10gDialect
org.hibernate.dialect.MySQL5Dialect
com.atlassian.bamboo.hibernate.SQLServer Intl Dialect
```

See also:
- the general update steps section above.
- the Bamboo 5.8 Release Notes.
- the Bamboo Supported platforms page.

If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

Upgrading to Bamboo 5.7...

Global deployment expiry

If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7. Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be removed. Most likely this is what you want but it's important to be aware of this change.

Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release.

Read more about global expiry in Bamboo 5.7.

See also:
- the general update steps section above.
- the Bamboo 5.7 Release Notes.
- the Bamboo Supported platforms page.

Upgrading to Bamboo 5.6...

Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated.
Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on Bitbucket Server.

**Update time**

When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the VARIABLE_CONTEXT table. For a more precise calculation, assume that 10 minutes are needed to process 15 million records in that table.

**Installer package on MAC OS X can not be opened due to code signing requirements**

*Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.6.*

Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

See also:

- the general update steps section above.
- the Bamboo 5.6 Release Notes.
- the Bamboo Supported platforms page.

**Upgrading to Bamboo 5.5...**

- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket servers. If you have previously integrated Bamboo with Bitbucket Server, you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but OAuth is a better as it is an impersonating authentication type. For more information, see Configuring authentication for an application link.
- Git will use --ancestry-path when trying to extract changeset due to

**BAM-13760** - Too many notifications for release -> feature merge in Git plan branches

Since that command is available for Git 1.7.2 and above (see Release Notes), please update your native Git, if you have Git 1.7.1 installed (especially those who use RHEL 6 or CentOS).

See also:

- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

**Upgrading to Bamboo 5.4...**

Note that Bamboo will run a full reindex after updating.

**Installer package on MAC OS X can not be opened due to code signing requirements**

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

See also:

- the general update steps section above.
- the Bamboo 5.4 release notes.
Troubleshooting

If you followed the documentation and you still have problems with the upgrade process:

- Check the How to Upgrade/Migrate Bamboo article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- You can also create a support ticket. To help us address the issue, attach the atlassian-bamboo.log file to the ticket.

Bamboo upgrade guide v6.7

You can upgrade Bamboo by installing a new version of Bamboo and setting it up with the configuration of the original Bamboo instance.

Overview

The recommended paths for upgrading Bamboo to a new version differ depending on whether you want to move to a new server or not:

<table>
<thead>
<tr>
<th>Upgrading Bamboo locally</th>
<th>Upgrading Bamboo with a move to a new server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform the steps as described on this page. Make sure that your new Bamboo instance is not installed in the same directory as the original Bamboo instance.</td>
<td>1. Clone your Bamboo instance into the new location. 2. Perform the upgrade steps on the cloned Bamboo instance as described on this page. The cloned instance on the new server is referred to as original Bamboo instance.</td>
</tr>
</tbody>
</table>

In both scenarios, the new Bamboo instance uses the home directory and the database of the original Bamboo instance.

We recommend that you test the Bamboo upgrade on a QA server before deploying to production.

If you are a Bamboo plugin developer, see our Bamboo API Changes by Version guide, which outlines changes in Bamboo that may affect Bamboo plugins compiled for earlier versions of Bamboo.

Before you begin

**Determine your upgrade path**

- When upgrading from very old versions of Bamboo, follow this upgrade path:

<table>
<thead>
<tr>
<th>OLDER VERSIONS</th>
<th>LATEST</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.5</td>
<td>2.0.6</td>
</tr>
<tr>
<td></td>
<td>2.6.3</td>
</tr>
<tr>
<td></td>
<td>2.7.4</td>
</tr>
<tr>
<td></td>
<td>5.0–5.7</td>
</tr>
</tbody>
</table>

- When upgrading from earlier than Bamboo 5.0, follow this upgrade path:

  | 4.0–4.4 | 5.14 | LATEST |

- When upgrading from Bamboo 5.0 and later, follow this upgrade path:

  | 5.0–5.13 | 5.14 | LATEST |

- When upgrading from Bamboo 5.14 and later, follow this upgrade path:

  | 5.14+    | LATEST |
Before you begin

- Read the specific upgrade notes for your version of Bamboo.
- Read End of support announcements for Bamboo.
- Check whether the system where you are going to install the new Bamboo instance meets the requirements.
- Check whether any add-ons may require an update.

The installation path is referred to as `<bamboo-install>` and points to the directory into which you extracted the Bamboo package. It is different from `<bamboo-home>`, which points to the directory where Bamboo data is stored.

1. Export and back up the existing Bamboo data

Export the Bamboo database

There are two database backup scenarios, depending on whether you are using an embedded or external database.

<table>
<thead>
<tr>
<th>Embedded HSQL database</th>
<th>External database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an export .zip file for the original Bamboo instance. For more information, see Exporting data for backup.</td>
<td>Use native database tools to create a backup. For more information about external databases, see Connecting Bamboo to an external database.</td>
</tr>
<tr>
<td>The export may take a long time to complete and may require a large amount of disk space, depending on the number of builds and tests in your system.</td>
<td></td>
</tr>
</tbody>
</table>

HSQL is not recommended for production Bamboo instances.

Stop Bamboo

Stop the original Bamboo instance.

If you have Bamboo running as a Windows service, uninstall the service by using the `UninstallService.bat` executable that came with your Bamboo instance.

Back up the Bamboo configuration

When the original Bamboo instance is shut down, back up your `<bamboo-home>` directory, which contains the builds and configuration directories. You can compress it into a .zip file.

Viewing Bamboo paths

Go to Administration > System > System information > Bamboo paths. Note the Bamboo home path, Build path, and Configuration path:

![Bamboo paths diagram]

For more information about these directories, see Important Directories and Files.
2. Download and install a new Bamboo instance

To upgrade Bamboo, you must install a new Bamboo instance in a `<bamboo-install>` directory that is different from the `<bamboo-install>` directory of the original Bamboo instance.

This upgrade scenario uses the home directory and the external database of the original Bamboo instance.

- Make sure that the original Bamboo instance is not running before you start the new installation.
- To prevent data loss during updates or reinstallation, the `<bamboo-home>` directory must be different from the `<bamboo-install>` directory.

Follow these guidelines to install a new Bamboo instance:

- **MacOS**
  - The Mac installer deletes the previous version of Bamboo.
  - Follow the Mac OS X install instructions.

- **Linux**
  - Delete your old `<bamboo-install>` directory to remove any legacy files.
  - Follow the Linux install instructions.

- **Windows**
  - The Windows installer deletes the previous version of Bamboo.
  - Follow the Windows install instructions.
  - Configure Bamboo to run as a service on Windows, using the `service.bat` executable.

3. Configure the new Bamboo instance

Set the home directory for the new Bamboo instance

Set the `<home-directory>` to use the `<home-directory>` of the original Bamboo instance:

1. Go to the new Bamboo instance `<bamboo-install>` directory. It is the directory where you installed Bamboo.
2. Open `atlassian-bamboo/WEB-INF/classes/bamboo-init.properties`

   For Bamboo versions prior to 5.1, the file path is: `<bamboo-install>/webapp/WEB-INF/classes/bamboo-init.properties`

3. Set the `bamboo.home` variable to use the `<bamboo-home>` path of the original Bamboo instance.

Reconnect external user directories (optional)

If you had integrated the original Bamboo instance with Crowd or LDAP, you must enable the integration for the new Bamboo instance.

For more information, see [Integrating Crowd with Bamboo](#) and [Integrating Bamboo with LDAP](#).

Update any installed add-ons

If you installed any add-ons in addition to the pre-installed system add-ons:

- Check if all add-ons are compatible with the new version of Bamboo.
- Update any add-ons that are out-of-date.
- Disable any add-ons that are incompatible with the new version of Bamboo.

Automatic update of remote agents

For Bamboo 3.2 and later, remote agents are updated automatically. Remote agents automatically detect when a new version is available and downloads new classes from the server.

For more information, see [Bamboo remote agent installation guide](#).

Migrate your existing Bamboo configurations over to your new Bamboo installation

If you have modified properties in configuration files of your existing Bamboo installation, make the same modifications in your new Bamboo installation. However, because the properties in the configuration files may have changed between versions, you cannot simply
copy the configuration files from your existing installation and replace the equivalent files in the new installation.

For each file you have modified in your existing Bamboo installation, you need to manually edit each equivalent file in your new Bamboo installation and re-apply your modifications.

The table below lists the most commonly modified files and their locations within your Bamboo Installation Directory:

<table>
<thead>
<tr>
<th>File</th>
<th>Location in Bamboo installation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setenv.bat (Windows) or setenv.sh (Linux)</td>
<td>bin</td>
<td>Configuring your system properties</td>
</tr>
<tr>
<td>seraph-config.xml</td>
<td>atlassian-bamboo/WEB-INF/classes</td>
<td>Modified if you had integrated Bamboo with Crowd</td>
</tr>
<tr>
<td>server.xml</td>
<td>conf</td>
<td>Modified in the following situations:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If you had previously changed Bamboo’s root context path.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If you had previously secured Bamboo with Tomcat using SSL or proxy server.</td>
</tr>
</tbody>
</table>

Check database access permission

Before you start the new Bamboo instance, make sure that it has the write access to the database, which is required to complete the upgrade tasks.

4. Start Bamboo

Start Bamboo

Once you have installed Bamboo and set the bamboo.home property, start the new Bamboo instance. The upgrade runs automatically. You can check whether the upgrade was successful in the atlassian-bamboo.log file.

Upgrading Bamboo may require reindexing.

Depending on the number of existing builds and tests, the reindexing process may take a significant amount of time, during which Bamboo will not be available.

Version-specific upgrade notes

The version-specific notes provide additional information to the main upgrade documentation. We recommend reading the version-specific notes for the original and new Bamboo instance versions.

- Upgrading to Bamboo 6.7...

Anonymous users remote repository trigger and Bamboo Specs detection disabled by default

Both remote repository trigger and Bambo Specs detection and by default disabled for anonymous users in Bamboo 6.7. Access to these by anonymous users is necessary e.g. for using webhooks. To enable it, go to

> Overview > Security settings.

When enabled, Bamboo ignores permissions settings for anonymous user access to those REST endpoints but keep restriction on other REST resources.

PostgreSQL 9.2 and 9.3 deprecated

Starting from version 6.7, Bamboo deprecates PostgresSQL 9.2 and 9.3. Support for these versions will end in an upcoming release.

Upgrade time

Bamboo 6.7 contains upgrade tasks for changes to the audit log table which can impact the upgrade time. The upgrade time can differ depending on the size of your audit log so plan some extra time when upgrading.

For reference, during our test, an audit log table with 6,5 records in PostgreSQL took 3 extra minutes of upgrade time.
Upgrading to Bamboo 6.6...

New upgrade threshold

We've made some changes to the possible Bamboo upgrade paths. To figure our the best way to upgrade your Bamboo to the latest version, see the upgrade path.

Heroku plugin not supported

Heroku's API changes rendered the Heroku plugin for Bamboo non-functional and we no longer deploy it with Bamboo. Check this DevCenter article on WAR Deployment for recommended alternatives.

See also:
- the general update steps section above.
- Bamboo 6.5 Release Notes
- the Bamboo Supported platforms page.

Upgrading to Bamboo 6.5...

See:
- the general update steps section above.
- Bamboo 6.5 Release Notes
- the Bamboo Supported platforms page.

Upgrading to Bamboo 6.4...

Hung Build Killer added to the add-on blacklist

Bamboo 6.4 is shipped with a native mechanism for monitoring builds. For that reason, the Hung Build Killer plugins becomes deprecated. See Add-on blacklist.

See also:
- the general update steps section above.
- Bamboo 6.4 Release Notes
- the Bamboo Supported platforms page.

Upgrading to Bamboo 6.3...

Change to the built-in database

Starting with Bamboo 6.3, the built-in HSQL database is replaced by H2. If you store any data in HSQL and want to keep it after the upgrade, you must export the data to XML and import back after you've installed the new version of Bamboo. See:
- Exporting data for backup
- Importing data from backup

The H2 database is fine for evaluation purposes but is somewhat susceptible to data loss during system crashes. For production environments we recommend that you configure Bamboo to use an external database.

See also:
- the general update steps section above.
- Bamboo 6.3 Release Notes
- the Bamboo Supported platforms page.

Upgrading to Bamboo 6.2...

See also:
- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

Upgrading to Bamboo 6.1...

See also:
- the general update steps section above.
- Bamboo 6.1 Release Notes
- the Bamboo Supported platforms page.

You might also want to check our Bamboo Specs reference documentation.

Upgrading to Bamboo 6.0...
Microsoft JDBC driver

With Bamboo 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver.

If database settings are configured directory in Bamboo, then during 6.0 upgrade it will attempt to update driver settings. In case of customized settings Bamboo instance administrator will be required to manually convert the settings.

If database settings are configured in the container (Tomcat) and Bamboo uses datasource, automatic upgrade will not be possible and instance administration will be required to manually convert the settings.

To learn more about this change, see [here](#).

New library for setting up a JNDI resource for SMTP

Bamboo 6.0 is shipped with the `javax.mail-api-1.5.6.jar` library. This library needs to copied over to your `<Bamboo-install>/lib` folder when setting up a JNDI resource for SMTP. For more information, see [here](#).

Changes to Git support

Starting from version 6.0, Bamboo changes support for Git to version 1.8.1.5 or later.

- **Upgrading to Bamboo 5.15...**
  Bamboo 5.15 contains upgrade tasks that can take extra time when moving from earlier versions of Bamboo. Keep this in mind when planning your upgrade outages.

- **Upgrading to Bamboo 5.14...**

  New API for VCS repositories

  We've rebuilt the repository subsystem, added new plugin points, and introduced new web repository viewers.

  **Action required**

  Before you upgrade to Bamboo 5.14, check for potential plugin incompatibilities, especially if you're using any plugins that aren't officially supported by Atlassian (third-party plugins, plugins developed in-house, or plugins marked as unsupported on Atlassian Marketplace).

  We strongly recommend reporting compatibility issues to the plugin vendor and Atlassian Support.

  For details about the API changes, see our developer documentation.

Changes in requirements for table names of the external databases

With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13. For more information, see:

- **Upgrading to Bamboo 5.13 below**
- **MySQL**
- **Bamboo 5.13 Release Notes**

  See also
  - the general update steps section above.
  - **Bamboo 5.14 Release Notes**
  - the Bamboo Supported platforms page.

  You might also want to check our developer documentation.

- **Upgrading to Bamboo 5.13...**

  Bamboo 5.13 introduces stricter verification of the external database configurations which prevents both upgrade and application start:

<table>
<thead>
<tr>
<th>Microsoft SQL Server</th>
<th>The check ensures that the tables in the Bamboo database have correct collation and correct commit isolation, see Microsoft SQL Server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>All DBs except SQL Server</td>
<td>The check ensures that the database engine is correctly configured to be case-insensitive. Make sure your specific database is configured correctly according to Connecting Bamboo to an external database. For MySQL specifically, this might affect all databases in the instance, see MySQL documentation.</td>
</tr>
</tbody>
</table>

  If the check fails

  If the check fails and you can't correct your database configuration immediately, you can roll back to the previous installed...
Changes to Clover Plugin integration

Automatic Clover integration for Maven 2 and Maven 3 tasks has been changed. It has tighter integration and adds Clover goals between goals from an original command so that a build will be performed only once (i.e. it will not run a separate build phase as it did before). Automatic Clover integration will not happen when your Maven task contains the `install` or `deploy` commands; this is to protect your repositories from being polluted by instrumented code. Therefore, please check if any of your Maven tasks that use automatic Clover integration use the `install` or `deploy` Maven commands. If they do: either disable automatic Clover integration for those jobs, or change the phase to the `verify` command (or earlier) or set up a dedicated job for Clover. Otherwise, your jobs will not produce Clover's coverage reports.

- the general update steps section above.
- Bamboo 5.9 Release Notes.
- the Bamboo Supported platforms page.

Upgrading to Bamboo 5.8...

Hibernate dialect update

When you upgrade to Bamboo 5.8, an upgrade task will run that changes the Hibernate dialect in the `bamboo.cfg.xml` file. The new dialects are:
See also:

- the general update steps section above.
- the Bamboo 5.8 Release Notes.
- the Bamboo Supported platforms page.

If you are upgrading from Bamboo versions earlier than Bamboo 4.0, you must upgrade to any of Bamboo 5.0–5.7 before upgrading to Bamboo 5.8.

### Upgrading to Bamboo 5.7...

**Global deployment expiry**

If you are updating to Bamboo 5.7 from 5.6 or earlier and you were previously using build expiry then the Global expiry page in Bamboo looks and works the same as it does in 5.6. In other words you are able to expire builds but not deployments. There is an option to enable deployment expiry however and selecting this option enables the new expiry features introduced in Bamboo 5.7. Note that this may mean that deployment artifacts and deployment result logs that were previously not being removed will start to be removed. Most likely this is what you want but it's important to be aware of this change.

Note also that enabling deployment expiry is not reversible. If you enable deployment expiry you will be unable to go back to the legacy Bamboo 5.6 behavior. The legacy Bamboo 5.6 behavior for expiry is deprecated and will be removed in a future release.

Read more about global expiry in Bamboo 5.7.

See also:

- the general update steps section above.
- the Bamboo 5.7 Release Notes.
- the Bamboo Supported platforms page.

### Upgrading to Bamboo 5.6...

**Bitbucket Server notifications and the Bitbucket Server web repository type are deprecated**

Bitbucket Server notifications and the legacy Bitbucket Server web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7. Use the Bitbucket Server repository integration available in Bamboo 5.6, which is based on application links, to replace that functionality. Read about using Bitbucket Server repositories with Bamboo on Bitbucket Server.

**Update time**

When scheduling the outage window for the Bamboo 5.6 update, keep in mind that update task 4407 that is executed during the update may take up to 45 minutes to complete on large instances, depending on the size of the VARIABLE_CONTEXT table. For a more precise calculation, assume that 10 minutes are needed to process 15 million records in that table.

**Installer package on MAC OS X can not be opened due to code signing requirements**

*Note, this issue was found in Bamboo 5.4 and still applies to Bamboo 5.6.*

Previously, Mac OS X required binaries to be Developer ID signed in order to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now reports that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see [BAM-11742](https://jira.atlassian.com/browse/BAM-11742) - Installer package is "damaged and cannot be reopened" on Mac OS X for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around available [here](https://jira.atlassian.com/wiki/display/BB/317+Implement+the+required+journaling+code+for+MacOS+X).

This is a small bug with our installer. Please be assured that we are working on a permanent solution to this issue.

See also:

- the general update steps section above.
- the Bamboo 5.6 Release Notes.
- the Bamboo Supported platforms page.
Upgrading to Bamboo 5.5...

- We recommend that you add OAuth authentication (in addition to existing authentication) to any existing application links between your Bamboo and Bitbucket servers. If you have previously integrated Bamboo with Bitbucket Server, you will probably have Basic HTTP authentication configured for your link. The new Bitbucket repository type will work with Basic HTTP, but OAuth is a better as it is an impersonating authentication type. For more information, see Configuring authentication for an application link.
- Git will use --ancestry-path when trying to extract changeset due to

```
BAM-13760 - Too many notifications for release -> feature merge in Git plan branches
```

Since that command is available for Git 1.7.2 and above (see Release Notes), please update your native Git, if you have Git 1.7.1 installed (especially those who use RHEL 6 or CentOS).

See also:
- the general update steps section above.
- the Bamboo 5.5 release notes.
- the Bamboo Supported platforms page.

Upgrading to Bamboo 5.4...

Note that Bamboo will run a full reindex after updating.

Installer package on MAC OS X can not be opened due to code signing requirements

Previously, Mac OS X required binaries to be Developer ID signed to run out of the box. Without signing, users would receive a warning that the app isn't from the App Store or a registered Apple Developer. Users were able to apply a work-around to solve this problem.

The latest version of Mac OS X (10.8 and above), however, now report that the Bamboo installer for Mac is corrupted rather than being blocked by developer ID.

Please see

```
BAM-11742 - Installer package is "damaged and cannot be reopened" on Mac OS X [RESOLVED]
```

for more information.

1. The Mac installer will not be available until this has been resolved
2. There is a temporary work-around solution available here.

This is a small bug with our installer, please rest assured that we are working on a permanent solution to this issue.

See also:
- the general update steps section above.
- the Bamboo 5.4 release notes.
- the Bamboo Supported platforms page.

Troubleshooting

If you followed the documentation and you still have problems with the upgrade process:

- Check the How to Upgrade/Migrate Bamboo article in the Bamboo Knowledge Base.
- Check other Knowledge Base articles.
- You can also create a support ticket. To help us address the issue, attach the atlassian-bamboo.log file to the ticket.

IPv6 in Bamboo

IPv6 in Bamboo v6.6

This feature is a part of the Bamboo 6.7 Early Access Program, which is are snapshots of the ongoing Bamboo development process. For that reason:

- While we try to keep these releases stable, they have not undergone the same degree of testing as a full release.
- Features in development releases maybe incomplete, or may change or be removed before the next full release.

Much as you are able to upgrade previous versions of Bamboo to the 6.7 EAP version, and smoothly upgrade from the 6.7 EAP to the final version, once it’s released, we don’t recommend installing the EAP release on your current production environment. For information about the supported upgrade paths, see Bamboo upgrade guide.

Starting from Bamboo 6.7, we’re supporting communication over IPv6. We’ve taken the dual-stack approach (IPv4 + IPv6), so IPv4 addresses will still work. If your systems are IPv6-only, make sure you read about the limitations below.

What is IPv6?

IPv6 stands for “Internet Protocol Version 6”, and is the next-generation Internet protocol designed to replace the current IPv4 protocol. The Internet Engineering Task Force (IETF) created IPv6 standard described in RFC 8200 to accommodate the growing

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
number of users and devices accessing the Internet.

IPv6 addresses are 128 bits, which allows for approx. $3.4 \times 10^{38}$ unique IP addresses. Here's an example of an IPv6 address:

```
2401:1d80:ffff:1:202:02ff:fe07:0305
```

**Best practices**

We recommend that you use hostnames or domain names instead of IP addresses everywhere in the Bamboo configuration. It's a more reliable way of configuring and accessing both Bamboo and other Atlassian products.

**Limitations**

**General**

These limitations apply if your systems use only IPv6 instead of dual-stack:

- You won't be able to connect to Atlassian Marketplace, as it requires IPv4.
- End of Life check won't work, because it needs to connect to Atlassian Marketplace.
- You won't be able to integrate with Atlassian Cloud products, as they require IPv4.
- Log Analyzer won't work, as it requires IPv4.
- When configuring LDAP, use hostnames, not IPv6 addresses. Otherwise, you'll get a validation error.
- Bamboo requires running with `java.net.preferIPv6Addresses` system property set to true, to operate normally in IPv6 environment.

**AWS**

There are no IPv6 endpoints for EC2, the only service that we use that has IPv6 endpoints is S3.

**Agents**

- Remote agents: tested in both IPv4 and IPv6 set ups.
- Remote agents authentication:
  - In case of IPv4 it is possible to use wildcards, e.g. 192.168.50.*
  - In case of IPv6 Use CIDR instead of wildcards: 2a05:d014:7d:801:b1a4:dec3::/32
- Elastic agents: required IPv4 as there are no IPv6 endpoints for EC2.

**RSS**

RSS requires dual stack IPv4/IPv6 set up to work properly in both Docker and without Docker modes. RSS is not supported in IPv6 pure set up.

**Docker**

- Requires dual stack (IPv4/IPv6) set up on host.
- Tested with Docker version: 18.03.1-ce.

**NPM task**

- Requires dual stack (IPv4/IPv6) set up on host.
- Tested with npm version: 5.6.0, node version: 8.11.3

**IM notifications**

- Tested with Openfire 4.2.3

**Databases connectivity**

- Oracle: tested with Oracle 12c
- MS SQL: tested with MS SQL 2016 Standard edition.
- PostgreSQL: tested with PostgreSQL 9.6.9 and 10.4
- MySQL: tested with JDBC Driver mysql-connector-java-8.0.11.jar and mysql-connector-java-5.1.46.jar, MySQL 5.7.2

**Repositories connectivity**

- Github: does not support IPv6.
- SVN: tested with SVNKit 1.8.15, SVN server - SVN 1.9.7. SVN server required the svnserve daemon to be run with `-6` option (--prefer-ipv6).
- Mercurial: tested SSH and HTTPS with Hg 4.2.3.
- Git: tested SSH/HTTPS/GIT protocols with git version 2.14.4
- Bitbucket Server: RSS won't work in pure IPv6 setup.
- Bitbucket Cloud: Required setting system property `-Djava.net.preferIPv6Addresses=true`, webhooks don't work over pure IPv6 setup.

**Integrations with other products**

- Bitbucket Server: supported since version 5.8
- FeCru: tested with version 4.5.4
- Jira: tested with Jira Software 7.11.0
- Confluence: tested with Confluence 6.10.1
- Crowd: tested with Crowd 3.2.3
Windows...

Bamboo doesn't expose port for IPv6 out of the box. To enable this, in the server.xml file, change:

```xml
<Connector/>
```
to

```xml
```

IPv6 in Bamboo v6.7

Starting from Bamboo 6.7, we're supporting communication over IPv6. We've taken the dual-stack approach (IPv4 + IPv6), so IPv4 addresses will still work. If your systems are IPv6-only, make sure you read about the limitations below.

What is IPv6?

IPv6 stands for “Internet Protocol Version 6”, and is the next-generation Internet protocol designed to replace the current IPv4 protocol. The Internet Engineering Task Force (IETF) created IPv6 standard described in RFC 8200 to accommodate the growing number of users and devices accessing the Internet.

IPv6 addresses are 128 bits, which allows for approx. $3.4 \times 10^{38}$ unique IP addresses. Here's an example of an IPv6 address:

```
2401:1d80:ffff:1:202:02ff:fe07:0305
```

Best practices

We recommend that you use hostnames or domain names instead of IP addresses everywhere in the Bamboo configuration. It's a more reliable way of configuring and accessing both Bamboo and other Atlassian products.

Limitations

General...

These limitations apply if your systems use only IPv6 instead of dual-stack:

- You won't be able to connect to Atlassian Marketplace, as it requires IPv4.
- End of Life check won't work, because it needs to connect to Atlassian Marketplace.
- You won't be able to integrate with Atlassian Cloud products, as they require IPv4.
- Log Analyzer won't work, as it requires IPv4.
- When configuring LDAP, use hostnames, not IPv6 addresses. Otherwise, you'll get a validation error.
- Bamboo requires running with `java.net.preferIPv6Addresses` system property set to true, to operate normally in IPv6 environment.

AWS...

There are no IPv6 endpoints for EC2, the only service that we use that has IPv6 endpoints is S3.

Agents...

- Remote agents: tested in both IPv4 and IPv6 set ups.
- Remote agents authentication:
  - In case of IPv4 it is possible to use wildcards, e.g. 192.168.50.*
  - In case of IPv6 Use CIDR instead of wildcards: 2a05:d014:77d:801:b1a4:dec3::/32
- Elastic agents: required IPv4 as there are no IPv6 endpoints for EC2.

RSS...

RSS requires dual stack IPv4/IPv6 set up to work properly in both Docker and without Docker modes. RSS is not supported in IPv6 pure set up.

Docker...

- Requires dual stack (IPv4/IPv6) set up on host.
- Tested with Docker version: 18.03.1-ce.

NPM task...

- Requires dual stack (IPv4/IPv6) set up on host.
- Tested with npm version: 5.6.0, node version: 8.11.3

IM notifications...

- Tested with Openfire 4.2.3

Databases connectivity...

- Oracle: tested with Oracle 12c
- MS SQL: tested with MS SQL 2016 Standard edition.
- PostgreSQL: tested with Postgres 9.6.9 and 10.4
- MySQL: tested with JDBC Driver mysql-connector-java-8.0.11.jar and mysql-connector-java-5.1.46.jar, MySQL 5.7.2
Repositories connectivity...
- Github: doesn’t support IPv6.
- SVN: tested with: SVNKit 1.8.15, SVN server - SVN 1.9.7, SVN server required the svnserve daemon to be run with --prefer-ipv6.
- Mercurial: tested SSH and HTTPS with Hg 4.2.3.
- Git: tested SSH/HTTPS/GIT protocols with git version 2.14.4
- Bitbucket Server: RSS won’t work in pure IPv6 setup.
- Bitbucket Cloud: Required setting system property -Djava.net.preferIPv6Addresses=true, webhooks don’t work over pure IPv6 setup.

Integrations with other products...
- Bitbucket Server: supported since version 5.8
- FeCru: tested with version 4.5.4
- Jira: tested with Jira Software 7.11.0
- Confluence: tested with Confluence 6.10.1
- Crowd: tested with Crowd 3.2.3

Windows...
Bamboo doesn’t expose port for IPv6 out of the box. To enable this, in the server.xml file, change:

```xml
<Connector />'s attribute protocol="HTTP/1.1"
```
to
```xml
```

Running Bamboo Server in AWS

There are no special prerequisites or configuration options required to run your server in AWS. If you’re an experienced AWS user, you can set up your instance using the regular installation instructions.

You may also choose to use our Bamboo Server EC2 Wizard, which will get your Bamboo server up and running in AWS in less than 10 minutes.

Prerequisites

- Amazon Web Services account access (you will need AWS Access and Secret Key, with sufficient access rights to run an instance and perform some maintenance tasks)
- Bamboo EC2 Wizard binary (download from here, optionally verify the SHA256 checksum)
- Java JRE 8 (download from here)

Outcome

After the wizard finishes, it will provide you with a HTTPS link to a Bamboo Server instance set up on Linux Ubuntu 16.04 LTS and Postgres DBMS. All data will be located on a separate persistent EBS volume.

Running the wizard

To run the wizard, execute:

```
java -jar bamboo-server-ec2-wizard.jar
```

You can safely execute that command - the wizard provides extensive guidance and will not perform any actions without asking for your permission.

FAQ

- **Does Atlassian have access to my EC2 instance or manage it any way?**
  No, we do not. In terms of access, support, or management, the instance does not differ from regular instances in any way. The instance can only be accessed using the SSH key provided by you during the installation (or generated by the wizard, if you chose that option).

- **Can I restart my EC2 instance without data loss?**
  Yes, you can restart your instance – the Bamboo server is set up to automatically start up after a restart of the EC2 instance.

- **Can I stop my EC2 instance?**
  Yes, in case you temporarily don't need your instance, it can be stopped.

- **Can I shut down my EC2 instance?**
  Yes. The data volume will not be destroyed during shutdown. You will be able to reattach it to a new instance later. You can also...
How can I add more resources (memory, CPU, I/O) to my EC2 instance?

Shut down your EC2 instance (note: stopping is not enough) and re-run the wizard. It will detect the data volume and offer you the option to reattach it. You will be able to select a new instance type. Use Amazon documentation to find an instance type more appropriate for your Bamboo server traffic.

How can I back up my Bamboo instance?

In the root directory of data volume (/media/atlassian-data) there's a script called backupInstance.sh. You will need to provide credentials with permissions to create EBS snapshots.

How can I upgrade Bamboo?

Note: before upgrading, Atlassian recommends backing up your data.

In the root directory of data volume (/media/atlassian-data) there's a script called upgradeBamboo.sh. Run it and give it a version number (or "latest") as a parameter, eg:

```
upgradeBamboo.sh 5.14.1
```

or

```
upgradeBamboo.sh latest
```

The script will stop your server, download the new Bamboo version, and start the server again. No additional steps are required.

I need shell access and I've lost my SSH key, how can I access the EC2 instance?

You can't. Shut down the instance and re-run the wizard, it will give you the option to start a new server using existing data. Remember to choose a new key.

I want to get rid of the privacy warning, what can I do?

You need to install a valid certificate instead of the default self-signed one. The files you need to replace are under /etc/apache2/ssl/.

What customisations are present on the EC2 instance after I run the wizard?

Overview of changes done by the wizard:

- a couple of packages (DBMS, java, git etc.) are installed using the standard packaging system
- the DBMS data directory is redirected to the EBS mount
- Bamboo start/stop script is added to startup scripts
- Apache reverse proxy setup
- HTTPS certificate is generated

In general, the changes are not fragile, so you should be able to add your customisations without problems.

Where do I request support/give feedback/report bugs?

Running Bamboo Server in AWS v5.14

There are no special prerequisites or configuration options required to run your server in AWS. If you're an experienced AWS user, you can set up your instance using the regular installation instructions.

You may also choose to use our Bamboo Server EC2 Wizard, which will get your Bamboo server up and running in AWS in less than 10 minutes.

Prerequisites

- Amazon Web Services account access (you will need AWS Access and Secret Key, with sufficient access rights to run an instance and perform some maintenance tasks)
- Bamboo EC2 Wizard binary (download from here, optionally verify the SHA256 checksum)
- Java JRE 8 (download from here)

Outcome

After the wizard finishes, it will provide you with a HTTPS link to a Bamboo Server instance set up on Linux Ubuntu 16.04 LTS and Postgres DBMS. All data will be located on a separate persistent EBS volume.
Running the wizard

To run the wizard, execute:

```
java -jar bamboo-server-ec2-wizard.jar
```

You can safely execute that command - the wizard provides extensive guidance and will not perform any actions without asking for your permission.

FAQ

Does Atlassian have access to my EC2 instance or manage it any way?

No, we do not. In terms of access, support, or management, the instance does not differ from regular instances in any way.

The instance can only be accessed using the SSH key provided by you during the installation (or generated by the wizard, if you chose that option).

Can I restart my EC2 instance without data loss?

Yes, you can restart your instance – the Bamboo server is set up to automatically start up after a restart of the EC2 instance.

Can I stop my EC2 instance?

Yes, in case you temporarily don't need your instance, it can be stopped.

Can I shut down my EC2 instance?

Yes. The data volume will not be destroyed during shutdown. You will be able to reattach it to a new instance later. You can also decide to destroy the data volume if you no longer need the data.

How can I add more resources (memory, CPU, I/O) to my EC2 instance?

Shut down your EC2 instance (note: stopping is not enough) and re-run the wizard. It will detect the data volume and offer you the option to reattach it. You will be able to select a new instance type. Use Amazon documentation to find an instance type more appropriate for your Bamboo server traffic.

How can I back up my Bamboo instance?

In the root directory of data volume (/media/atlassian-data) there's a script called backupInstance.sh. You will need to provide credentials with permissions to create EBS snapshots.

How can I upgrade Bamboo?

Note: before upgrading, Atlassian recommends backing up your data.

In the root directory of data volume (/media/atlassian-data) there's a script called upgradeBamboo.sh. Run it and give it a version number (or "latest") as a parameter, eg:

```
upgradeBamboo.sh 5.14.1
```

or

```
upgradeBamboo.sh latest
```

The script will stop your server, download the new Bamboo version, and start the server again. No additional steps are required.

I need shell access and I've lost my SSH key, how can I access the EC2 instance?

You can't. Shut down the instance and re-run the wizard, it will give you the option to start a new server using existing data. Remember to choose a new key.

I want to get rid of the privacy warning, what can I do?

You need to install a valid certificate instead of the default self-signed one. The files you need to replace are under /etc/apache2/ssl/.
What customisations are present on the EC2 instance after I run the wizard?

Overview of changes done by the wizard:

- A couple of packages (DBMS, java, git etc.) are installed using the standard packaging system
- The DBMS data directory is redirected to the EBS mount
- Bamboo start/stop script is added to startup scripts
- Apache reverse proxy setup
- HTTPS certificate is generated

In general, the changes are not fragile, so you should be able to add your customisations without problems.

Where do I request support/give feedback/report bugs?

Running Bamboo Server in AWS v5.15

There are no special prerequisites or configuration options required to run your server in AWS. If you're an experienced AWS user, you can set up your instance using the regular installation instructions.

You may also choose to use our Bamboo Server EC2 Wizard, which will get your Bamboo server up and running in AWS in less than 10 minutes.

Prerequisites

- Amazon Web Services account access (you will need AWS Access and Secret Key, with sufficient access rights to run an instance and perform some maintenance tasks)
- Bamboo EC2 Wizard binary (download from here, optionally verify the SHA256 checksum)
- Java JRE 8 (download from here)

Using Bamboo

Atlassian Bamboo is a continuous integration (CI) and continuous delivery (CD) server. Bamboo assists software development teams by providing:

- automated building and testing of software source-code status.
- updates on successful/failed builds.
- reporting tools for statistical analysis.
- visibility into, and control over, release artifacts and environments.

This section has information about using Bamboo. Please see Administering Bamboo for information about managing the Bamboo server itself.

**Continuous integration**
- Understanding the Bamboo CI Server
- Configuring plans
- Linking to source code repositories
- Jobs and tasks
- Working with builds
- Sharing artifacts

**Continuous delivery**
- Understanding deployment releases
- Deployment projects
- A sample deployment project
- Creating a deployment project
- Creating a deployment environment

**See also**

- Installing and upgrading
- Integrating Bamboo with Atlassian applications
Configuring plans

A plan defines everything about your continuous integration build process in Bamboo.

A plan:

- Has a single stage, by default, but can be used to group jobs into multiple stages.
- Processes a series of one or more stages that are run sequentially using the same repository.
- Specifies the default repository.
- Specifies how the build is triggered, and the triggering dependencies between the plan and other plans in the project.
- Specifies notifications of build results.
- Specifies who has permission to view and configure the plan and its jobs.
- Provides for the definition of plan variables.

Every plan belongs to a project.

Projects and plans can only be configured by Bamboo administrators (see Creating a plan).

On this page:

- Navigate to a plan’s configuration
- Configure a plan
- Viewing plan configuration in the YAML format

Navigate to a plan’s configuration

Choose Build > All build plans from the Bamboo header, then click the edit icon (STRUCTOR) for the plan you want to edit.

The plan’s configuration is found on several tabs. you can also view the configuration in the YAML format:

Configure a plan

1. Navigate to the plan’s configuration pages as described above.
2. Click a tab to configure that aspect of your plan:

<table>
<thead>
<tr>
<th>Plan details</th>
<th>A plan’s Project Key and Plan Key are not editable once the plan is created, however see Moving plans to a different project.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stages</td>
<td>See Using stages in a plan.</td>
</tr>
<tr>
<td>Repositories</td>
<td>See Linking to source code repositories.</td>
</tr>
<tr>
<td>Triggers</td>
<td>See Triggering builds.</td>
</tr>
<tr>
<td>Branches</td>
<td>See Using plan branches.</td>
</tr>
<tr>
<td>Dependencies</td>
<td>See Setting up build dependencies.</td>
</tr>
<tr>
<td>Permissions</td>
<td>See Configuring a plan’s permissions.</td>
</tr>
<tr>
<td>Notifications</td>
<td>See Configuring notifications.</td>
</tr>
<tr>
<td>Variables</td>
<td>See Defining plan variables.</td>
</tr>
<tr>
<td>Miscellaneous</td>
<td>See Configuring expiry of a plan’s build results.</td>
</tr>
<tr>
<td>Audit log</td>
<td>A record of changes to the plan’s configuration. This feature is disabled by default. To enable it, please go to Administration &gt; System &gt; Audit Log.</td>
</tr>
</tbody>
</table>

Viewing plan configuration in the YAML format

Bamboo instance administrators can view the plan configuration in the YAML format in Plan configuration > Actions.
Viewing a plan’s build information

A plan defines everything about your continuous integration build process in Bamboo.

To view information about a plan:

1. Navigate to the desired plan, as follows:
   - If you are viewing the Dashboard, locate and click the plan’s name in the list, or
   - If you are viewing a job or build result, click the plan name in the breadcrumb links at the top of the screen.
2. Click a tab to view information about the plan:

<table>
<thead>
<tr>
<th>Tab</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plan Summary</td>
<td>Information about the plan, as shown in the diagram below.</td>
</tr>
<tr>
<td>Branches</td>
<td>The branch plans for this plan.</td>
</tr>
<tr>
<td>Recent Failures</td>
<td>Information about recent failures of the plan, including the builds that failed, links to the build results, time taken to fix, etc.</td>
</tr>
<tr>
<td>History</td>
<td>The full history of builds of the plan.</td>
</tr>
<tr>
<td>Tests</td>
<td>A summary of the 10 most frequently broken tests.</td>
</tr>
<tr>
<td>Quarantined Tests</td>
<td>Failing test’s results that have been disconnected from the build results.</td>
</tr>
<tr>
<td>Issues</td>
<td>View the Jira issues linked to builds of your plan. <em>(You will only see this if your administrator has integrated Bamboo with Jira.)</em></td>
</tr>
</tbody>
</table>

Use the Actions menu to access functions for the plan, such as Disable Plan and Configure Plan. *(This menu is only displayed if you are an administrator for the plan.)*
To view information about a plan:

1. Navigate to the desired plan, as follows:
   - If you are viewing the Dashboard, locate and click the plan’s name in the list, or
   - If you are viewing a job or build result, click the plan name in the breadcrumb links at the top of the screen.
2. Click a tab to view information about the plan:

   Related pages:

A **plan** defines everything about your continuous integration build process in Bamboo.

# Viewing a plan's build information v6.1

To view information about a plan:

1. Navigate to the desired plan, as follows:
   - If you are viewing the Dashboard, locate and click the plan's name in the list, or
   - If you are viewing a job or build result, click the plan name in the breadcrumb links at the top of the screen.
2. Click a tab to view information about the plan:

   **Related pages:**
   - Using the Bamboo dashboard
   - Viewing a build result
   - Configuring plans
   - Configuring a plan's permissions

<table>
<thead>
<tr>
<th>Tab</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Plan Summary</strong></td>
<td>Information about the plan, as shown in the diagram below.</td>
</tr>
<tr>
<td><strong>Branches</strong></td>
<td>The branch plans for this plan.</td>
</tr>
<tr>
<td><strong>Recent Failures</strong></td>
<td>Information about recent failures of the plan, including the builds that failed, links to the build results, time taken to fix, etc.</td>
</tr>
</tbody>
</table>
1. **Navigation**: Click the project to view a summary of its plans.
2. **Tabs**: View further details for the plan.
3. **Current activity and recent history**: See whether the plan is building. Shows results for the ten most recent plan builds. Click a build number to view that build result.
4. **Run menu**: Choose options for running the plan, e.g., run a parameterised build.
5. **Plan status**: Icons show if the plan is building and the status of recent builds. Click an icon to see the build result.
6. **Actions menu**: E.g., Configure Plan or Disable Plan
7. **Statistics and charts**: For the build history of the plan.
8. **Plan branches**: A summary of all the branches for the plan.

### Creating a plan

A plan defines everything about your build process, including what gets built, how the build is triggered and what jobs are executed.

This page describes how to:

- Create a new plan
- Clone an existing plan

Note, you need the Create User or Admin global permission to create or clone a plan.

### Create a new plan

1. **Click Create > Create a new plan** in the top menu bar. Complete the build plan details on the Configure plan page:

   - **Project**: The name of your build project.
1. **Plan name**
   The name of your build plan.

2. **Plan key**
   The key for your build plan.

3. **Plan description**
   A brief description of the build plan's function or purpose.

2. Choose from either a previously used repository, or link to a new repository.

   If you want to link a new repository, select your code repository host from the options:

   - **Stash (Bitbucket Server)**
     An enterprise Git repository tool by Atlassian. [Learn more...](#)

   - **Bitbucket (Bitbucket Cloud)**
     A free code DVCS hosting site for Git and Mercurial. [Learn more...](#)

   - **Other**
     A range of other repository hosts is also supported:
     - Git
     - GitHub
     - Mercurial
     - Subversion
     - CVS
     - Perforce

   You may need to supply additional information depending on your code repository. Go to the next step when done.

   If you have previously linked a repository, then you may select it again, search for an alternative host or link a new one. Use the repository picker to select one of your existing linked repositories. Click [Configure plan](#) and you are done. You can now configure the tasks and jobs required by your build plan.

3. **Link repository to new build plan**

   - **Repository host**
     - Previously linked repository
     - Bamboo Master

   - **Link new repository**

4. **Configure plan**

   - **Allow all users to reuse the configuration of this repository**
     All user access. This is the default access setting.

   - **Only you are allowed to reuse the configuration of this repository**
     Limit access to just yourself.

   You can now configure the tasks and jobs required by your build plan.

5. **Clone an existing plan**

   When you clone an existing plan, you make a copy of that plan and its entire configuration, with the exception of any branches:

   1. Click [Clone an existing plan](#) in the top menu bar.
   2. Use [Plan to clone](#) to select a plan. Only plans for which you have the 'Clone' and/or 'Admin' plan permission are shown.
   3. Choose an existing project for the plan, or create a new project.
   4. Enter details for the new plan.
   5. Choose whether to enable this plan. Enabling the plan instructs Bamboo to start running builds of the plan, based on the plan's trigger configuration.
   6. When you click [Create](#), the 'Plan Summary' page for the new plan will be displayed. Bamboo will automatically run an initial build for
Creating a plan v5.14

A plan defines everything about your build process, including what gets built, how the build is triggered and what jobs are executed.

This page describes how to:

- Create a new plan
- Clone an existing plan

Note, you need the Create User or Admin global permission to create or clone a plan.

Create a new plan

1. Click Create > Create a new plan in the top menu bar. Complete the build plan details on the Configure plan page:

<table>
<thead>
<tr>
<th>Project</th>
<th>The name of your build project</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plan name</td>
<td>The name of your build plan</td>
</tr>
<tr>
<td>Plan key</td>
<td>The key for your build plan</td>
</tr>
<tr>
<td>Plan description</td>
<td>A brief description of the build plan's function or purpose</td>
</tr>
</tbody>
</table>

2. Choose from either a previously used repository, or link to a new repository.

If you want to link a new repository, select your code repository host from the options:

- Stash (Bitbucket Server) An enterprise Git repository tool by Atlassian. Learn more...
- Bitbucket (Bitbucket Cloud) A free code DVCS hosting site for Git and Mercurial. Learn more...
- Other A range of other repository hosts is also supported:
  - Git
  - GitHub
  - Mercurial
  - Subversion
  - CVS
  - Perforce

You may need to supply additional information depending on your code repository. Go to the next step when done.

If you have previously linked a repository, then you may select it again, search for an alternative host or link a new one. Use the repository picker to select one of your existing linked repositories. Click Configure plan and you are done. You can now configure the tasks and jobs required by your build plan.

Link repository to new build plan

Repository host

<table>
<thead>
<tr>
<th>Previously linked repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bamboo Master</td>
</tr>
</tbody>
</table>

Link new repository

3. Select the repository and branch for your plan.
4. Specify access to the repository. You may choose from:

<table>
<thead>
<tr>
<th>Allow all users to reuse the configuration of this repository</th>
<th>All user access. This is the default access setting.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only you are allowed to reuse the configuration of this repository</td>
<td>Limit access to just yourself.</td>
</tr>
</tbody>
</table>
5. You can now configure the tasks and jobs required by your build plan.

*Clone an existing plan*

When you clone an existing plan, you make a copy of that plan and its entire configuration, with the exception of any branches:

1. Click Create > Clone an existing plan in the top menu bar.
2. Use Plan to clone to select a plan. Only plans for which you have the 'Clone' and/or 'Admin' plan permission are shown.
3. Choose an existing project for the plan, or create a new project.
4. Enter details for the new plan.
5. Choose whether to enable this plan. Enabling the plan instructs Bamboo to start running builds of the plan, based on the plan’s trigger configuration.
6. When you click Create, the 'Plan Summary' page for the new plan will be displayed. Bamboo will automatically run an initial build for your new plan.

Creating a plan v6.1

A plan defines everything about your build process, including what gets built, how the build is triggered and what jobs are executed.

This page describes how to:

- Create a new plan
- Clone an existing plan

Note, you need the Create User or Admin global permission to create or clone a plan.

*Create a new plan*

1. Click Create > Create a new plan in the top menu bar. Complete the build plan details on the Configure plan page:

   - **Project**
     The name of your build project.

   - **Plan name**
     The name of your build plan.

   - **Plan key**
     The key for your build plan.

   - **Plan description**
     A brief description of the build plan's function or purpose.

2. Choose from either a previously used repository, or link to a new repository.

   If you want to link a new repository, select your code repository host from the options:

   - **Stash (Bitbucket Server)**
     An enterprise Git repository tool by Atlassian. Learn more...

   - **Bitbucket (Bitbucket Cloud)**
     A free code DVCS hosting site for Git and Mercurial. Learn more...

   - **Other**
     A range of other repository hosts is also supported:

     - Git
     - GitHub
     - Mercurial
     - Subversion
     - CVS
     - Perforce

   You may need to supply additional information depending on your code repository. Go to the next step when done.

   If you have previously linked a repository, then you may select it again, search for an alternative host or link a new one. Use the repository picker to select one of your existing linked repositories. Click **Configure plan** and you are done. You can now configure the tasks and jobs required by your build plan.
### Link repository to new build plan

Repository host  
- Previously linked repository
- Link new repository

[Configure plan] [Cancel]

3. Select the repository and branch for your plan.
4. Specify access to the repository. You may choose from:
   - **Allow all users to reuse the configuration of this repository**
     - All user access. This is the default access setting.
   - **Only you are allowed to reuse the configuration of this repository**
     - Limit access to just yourself.
5. You can now configure the tasks and jobs required by your build plan.

### Clone an existing plan

When you clone an existing plan, you make a copy of that plan and its entire configuration, with the exception of any branches:

1. Click **Create > Clone an existing plan** in the top menu bar.
2. Use **Plan to clone** to select a plan. Only plans for which you have the 'Clone' and/or 'Admin' plan permission are shown.
3. Choose an existing project for the plan, or create a new project.
4. Enter details for the new plan.
5. Choose whether to enable this plan. Enabling the plan instructs Bamboo to start running builds of the plan, based on the plan's trigger configuration.
6. When you click **Create**, the 'Plan Summary' page for the new plan will be displayed. Bamboo will automatically run an initial build for your new plan.

### Creating a plan v6.4

A plan defines everything about your build process, including what gets built, how the build is triggered and what jobs are executed.

This page describes how to:

- Create a new plan
- Clone an existing plan

Note, you need the **Create User** or **Admin** global permission to create or clone a plan.

### Create a new plan

1. In the top menu bar, click **Create > Create plan**.
2. Complete the build plan details on the Configure plan page.
3. Link repository to new build plan:
   - link previously used repository OR
   - link to a new repository...
     a. Select your code repository host.
     b. Give your repository a display name.
     c. Provide repository URL.
     d. Specify access to the repository. You may choose from:
        - **Allow all users to reuse the configuration of this repository**
          - All user access. This is the default access setting.
        - **Only you are allowed to reuse the configuration of this repository**
          - Limit access to just yourself.

   For more information about source code repositories in Bamboo, see [Linking to source code repositories](#).

4. Click **Configure plan** and you are done.
   You can now configure the tasks and jobs required by your build plan.

### Clone an existing plan

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
When you clone an existing plan, you make a copy of that plan and its entire configuration, with the exception of any branches:

1. Click **Create** > **Clone an existing plan** in the top menu bar.
2. Use **Plan to clone** to select a plan. Only plans for which you have the 'Clone' and/or 'Admin' plan permission are shown.
3. Choose an existing project for the plan, or create a new project.
4. Enter details for the new plan.
5. Choose whether to enable this plan. Enabling the plan instructs Bamboo to start running builds of the plan, based on the plan's trigger configuration.
6. When you click **Create**, the 'Plan Summary' page for the new plan will be displayed. Bamboo will automatically run an initial build for your new plan.

### Using plan branches

Plan branches are used to represent a branch in your version control repository, with the plan branch using the same build configuration as your plan.

Tools such as Git and Mercurial encourage a practice called feature branching, where a developer can use a new branch to work in isolation from his or her team members before merging their changes back into main line development.

With plan branches in Bamboo:

- Any new branch created in the repository can be automatically built and tested using the same build configuration as that of the parent plan.
- Any branches deleted from the repository can be deleted automatically from Bamboo according to the settings.
- You have the flexibility to individually configure branch plans, by overriding the parent plan, if required.
- Optionally, changes from the feature branch can be automatically merged back to the "master" (e.g. trunk, default or mainline branch) when the build succeeds.

You can customize how Bamboo manages branches on the system, plan, and branch levels.

**Managing plan branches in Bamboo**

You can create plan branches manually or automatically. The branch configuration can be provided on the plan level and customized on the branch level. The settings provided in the branch configuration override the settings provided for the plan.

Use the **Branch status** page for quick access to plan branch information.

You can access the list of all branches in a plan from different places. For example, you can click the **Branch** icon next to the plan name in the **Build Dashboard** view:
1. You can also access the branch list from the Plan summary view:

Subversion branches location

This section is displayed only for plans that use a Subversion source repository. Bamboo assumes that your Subversion repository structure follows the convention for branches, and automatically calculates the branch root URL.

For example, for the fastBuild repo with this URL: https://svn.mycompany.com/svn/fastBuild/trunk, Bamboo will expect that branches will be created at this location: https://svn.mycompany.com/svn/fastBuild/branches.

If your Subversion repository structure follows a different convention, you can specify where repository branches will be created by selecting Change subversion branches URL.

Automatic branch management

Plan branches can be created and deleted automatically based on the updates in the primary source repository. Automatic branch management is available for Git, Mercurial, and Subversion. For other repository types, you can use manual branching. You can override the default settings for a branch, such as values of the variables.

By default, automatic branch management is:

- disabled for branches that you create manually
- enabled for branches that are created automatically

You can specify how often Bamboo checks the primary source repository for new or deleted branches in the general branch settings.

You can override the branch deletion settings in the branch details configuration view.

To hand over the branch management to Bamboo:

1. Go to the Plan Configuration view: in the Plan summary view, click the Actions button
1. **Configure plan**

2. Click the **Branches** tab.
   a. Configure the following:

<table>
<thead>
<tr>
<th>Action</th>
<th>Primary source repository branches</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create plan branch</td>
<td>Manually</td>
<td>Bamboo doesn't create new plan branches automatically. You can create branches manually.</td>
<td></td>
</tr>
<tr>
<td>When pull request is created</td>
<td></td>
<td>Bamboo creates a plan branch automatically when a new pull request is created. If a pull request is merged or declined, Bamboo will disable this plan branch. Note that this option is available for environment that provide support for pull requests. Currently, these are Bitbucket Server, and Bitbucket Cloud.</td>
<td></td>
</tr>
<tr>
<td>When new branch in repository is created</td>
<td></td>
<td>Bamboo creates a plan branch for each new branch detected in the primary source repository.</td>
<td></td>
</tr>
<tr>
<td>When new branch in repository is created and matches expression</td>
<td></td>
<td>Bamboo creates a plan branch for each new branch detected in the primary source repository that matches the regular expression that you provided.</td>
<td></td>
</tr>
</tbody>
</table>

| Delete plan branch            | After branch was deleted from repository | When a branch is deleted from the repository, Bamboo will wait for provided number of days before deleting the plan branch. | If you selected **Clean up plan branch automatically** in the configuration on the branch level, the branch is disabled and deleted according to the daily cleanup rules, regardless of the automatic branch management settings. |
| After branch inactivity in repository |                                    | When a branch is inactive for provided number of days, Bamboo will delete the plan branch. If a branch in the primary source repository is inactive, Bamboo does not automatically delete the corresponding plan branch. |

3. Click **Save** at the bottom of the view to apply the changes.

### Global settings - branch detection interval

Once plan branching is enabled, Bamboo checks for new or deleted branches in the primary source code repository.

You can specify how often Bamboo checks for new branches in the primary source repository in the system settings. The default value is 300 seconds.

To configure the branch detection interval:

1. **Open the Bamboo Administration view by clicking the cog icon**
   and selecting a section from the list that opens.
2. In the **Bamboo Administration** view, scroll down the menu on the left to find the **System** section.
3. **Click General configuration.**
4. In **Global system configurations**, set the branch detection interval. Provide the value in seconds, the default value is 300.

### Manual branch management

Use manual branching for all supported repository types. You may want to consider using automatic branch management for Git, Mercurial and Subversion repositories.

To manually create a branch of a plan:

1. **Go to the Plan Configuration view:** in the Plan summary view, click the **Actions** button
   and select **Configure plan**
2. Click the **Branches** tab.
3. Click **Create plan branch** in the upper right of the view.
4. In the **Create plan branch** view, you can create branches in one of the following ways:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select from available VCS branches</td>
<td>Select one or more branches from the list of available VCS branches. At the bottom of the list of the branches you can select the <strong>Enable branches</strong> check box, which makes all selected branches available for building and change detection.</td>
</tr>
</tbody>
</table>
| Create plan branch manually     | Provide:  
- a display name (required) - overrides the VCS branch name  
- a branch description - a meaningful description of the branch  
- VCS branch name - the name of the branch in the VCS repository  
You can select the **Enable branches** check box, which makes the new branch available for building and change detection.  
Click **Auto-detect VCS** branches to go back to the list of available VCS branches. |

5. Click **Save**.

**Integrating branches with Jira applications**

Check **Create Remote Links from Jira Issues** to have the plan branch automatically linked, using an issue key in the branch name.

When a developer begins working on a feature described in a Jira application issue, they use Git or Mercurial to branch the repository. If they use the issue key as part of the VCS branch name, Bamboo will detect the issue key and automatically link the new branch to the issue:

- The Jira application issue key needs to be in the name of the branch – ’jb-BDEV-790’ and ‘BDEV-769 1’ are valid forms.
- The link shows up right under the breadcrumb on the Build Result Summary for the plan branch, and on the issue too.

To use Jira applications Feature Branching, Bamboo needs an **application link** to the Jira application server.

**Branch repositories**

Once the plan branch is created, automatically or manually, all repositories defined in the plan inherit settings from the master plan by default. The only exception is the default repository, which uses one of the following branches:

- branch selected by you during the manual creation of the plan,  
- branch detected in VCS in case of automatically created plan.

You can change settings of all repositories defined in the plan branch in the **Repositories** tab. In this tab, simply put a desired branch name or enable the **Change repository settings for this branch plan** toggle if you need to modify more settings.

In the **Branch summary** tab the **Repository branches** section gives you a quick overview of repositories and branches configured in the plan branch. The **Default repository settings changed** flag indicates that this repository overrides more settings from the parent plan. The **No branch support flag** means that a given repository type does not support branches.
Branch notifications

You can get build notifications from branch plans just as you do for master plans.

To specify how notifications are sent by all branches created from a plan, go to the Branches tab for the plan's configuration and choose one of the following options:

- Notify committers and people who have favorited this branch.
- Use the plan's notification settings.
- Notifications should not be sent for this branch.

You can override how notifications are sent from a particular branch plan, if necessary, by going to the Notifications tab on the Plan Branch configuration.

See Configuring notifications for a plan and its jobs for information about plan notifications.

Branch dependencies

You can use build dependencies for branch plans in a similar way to that for plans: a branch plan is triggered only when another branch plan has been successfully built. This can be used to ensure that breaking source code changes associated with one branch plan are detected before they can break the build of a dependent branch plan. Dependencies between master plans are maintained if their branch plans have the same name. See Setting up plan build dependencies for further information about dependencies.

Select Trigger Dependencies for Branches, on the Dependencies tab for the plan configuration, if you want plan branches to honor the build dependencies of their respective master plans.

Branch details configuration

Whether a plan branch is created automatically or manually, the master plan maintains the structure and configuration of it's branch plans. However, you can go to the configuration pages to override the following settings in a branch plan:

Branch clean-up

On the Branch Details tab of the branch's configuration, you can specify that a plan branch is not cleaned up automatically.

Please note that 'Automatic Branch Clean-up' is supported for Mercurial, Git (Bamboo 4.1.1 and above) and Subversion (Bamboo 4.2.0 and above).

By default, plan branches are deleted automatically after:

- 7 days after the branch was deleted in the primary source repository OR
- 10 days of branch inactivity in the primary source repository

The values can be specified on the plan level.

Trigger type

On the Branch Details tab of the branch's configuration. See Triggering builds.

Note that you can only configure one trigger for a plan branch, and that this overrides all triggers that may be configured for the master plan.

Merging

On the Branch Details tab of the branch's configuration. Described below.

Source repository

On the Source Repository tab of the plan branch configuration. You can override the default repository settings of a plan on the branch level:
Notifications

On the Notifications tab of the branch’s configuration. The options are:

- Notify committers and people who have favorited this branch.
- Use the plan’s notification settings.
- Notifications should not be sent for this branch.

See Configuring notifications for a plan and its jobs for information about plan notifications.

Variables

On the Variables tab of the branch’s configuration. See Defining plan variables.

Automatic branch merging

Bamboo provides 2 merging models if you choose to automate your branch merging:

- **Branch Updater** — a branch repo is kept up-to-date with changes to master. Note that changes on your master branch do not trigger branch builds.
- **Gatekeeper** — the default repo is only updated with changes in the branch that have built successfully.

The automatic branch merge strategy for the master plan can be overridden in an individual plan branch, if required. Automatic branch merging is not available for Subversion.
**Branch updater**

**When to use**
The Branch Updater should be used when you want to:

- Automatically merge changes from the team's master branch into your feature branch, after a successful build of the master branch.
- Get notified when the changes on your feature branch are no longer compatible with the team's master branch.

**Configuring**
To have recent changes in another repo merged into your branch repo:

1. Go to the Branch Details tab of the branch plan's configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Branch Updater.
3. Use the Merge From list to choose the repo from which changes should be merged with your feature branch.
4. Select Push on only if you want those changes merged back into your branch once the build completes successfully.
5. Click Save.
Gatekeeper

When to use

The Gatekeeper should be used when you want to:

- Automatically merge your feature branch back into the team's master branch, after a successful build of the merged changes from both branches.
- Get notified when a build of combined changes from both branches fails, preventing the feature branch from being merged back into the team's master branch.

Configuring

To have your successfully built changes pushed to another repo:

1. Go to the Branch Details tab of the branch plan's configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Gate Keeper.
3. Use the Checkout list to choose the repo with which to merge your changes (and to which changes should be pushed).
4. Select Push on only if you want your changes pushed to the other repo once the build completes successfully.
5. Click Save.

Limitations with plan branches

The following limitations apply to using automated plan branching and merging:

<table>
<thead>
<tr>
<th>Action</th>
<th>Limitations</th>
</tr>
</thead>
</table>

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Auto plan branching

- Can only be used with Git, Mercurial and Subversion repositories. For other repository types, use manual branching.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)

Manual plan branching

- Can be used for all repository types supported by Bamboo.

Auto branch merging

- Can only be used with Git and Mercurial repositories.
- Can only be used with branches that were configured in Bamboo.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)

Branches wallboard

The branches wallboard displays the status of all the branches and the plan that the branches belong to. The plan's own status always appears first. Plans shown as grey are disabled.

To display the branches wallboard:

1. Go to the Plan Summary for the plan that has branches you want to display.
2. Choose Actions > Branch Wallboard.

Plan branches v5.14

Plan branches are used to represent a branch in your version control repository, with the plan branch using the same build configuration as your plan.

Tools such as Git and Mercurial encourage a practice called feature branching, where a developer can use a new branch to work in isolation from his or her team members before merging their changes back into main line development.

With plan branches in Bamboo:

- Any new branch created in the repository can be automatically built and tested using the same build configuration as that of the parent plan.
- Any branches deleted from the repository can be deleted automatically from Bamboo according to the settings.
- You have the flexibility to individually configure branch plans, by overriding the parent plan, if required.
- Optionally, changes from the feature branch can be automatically merged back to the "master" (e.g. trunk, default or mainline branch) when the build succeeds.

You can customize how Bamboo manages branches on the system, plan, and branch levels.

- Atlassian Git Tutorial
- Feature branches explained
Managing plan branches in Bamboo

You can create plan branches manually or automatically. The branch configuration can be provided on the plan level and customized on the branch level. The settings provided in the branch configuration override the settings provided for the plan.

Use the Branch status page for quick access to plan branch information.

You can access the list of all branches in a plan from different places. For example, you can click the Branch icon next to the plan name in the Build Dashboard view:

![Build Dashboard view](image)

You can also access the branch list from the Plan summary view:

![Plan summary view](image)

Subversion branches location

This section is displayed only for plans that use a Subversion source repository. Bamboo assumes that your Subversion repository structure follows the convention for branches, and automatically calculates the branch root URL.

For example, for the fastBuild repo with this URL: https://svn.mycompany.com/svn/fastBuild/trunk, Bamboo will expect that branches will be created at this location: https://svn.mycompany.com/svn/FastBuild/branches.
If your Subversion repository structure follows a different convention, you can specify where repository branches will be created by selecting **Change subversion branches URL**.

### Automatic branch management

Plan branches can be created and deleted automatically based on the updates in the primary source repository. Automatic branch management is available for Git, Mercurial, and Subversion. For other repository types, you can use **manual branching**. You can override the default settings for a branch, such as values of the variables.

By default, automatic branch management is:

- disabled for branches that you create manually
- enabled for branches that are created automatically

You can specify how often Bamboo checks the primary source repository for new or deleted branches in the **general branch settings**. You can override the branch deletion settings in the **branch details configuration** view.

To hand over the branch management to Bamboo:

1. Go to the **Plan Configuration view**: in the Plan summary view, click the **Actions** button and select **Configure plan**
2. Click the **Branches** tab.
3. In the **Automatic branch management** section, configure the following:

<table>
<thead>
<tr>
<th>Primary source repository branches</th>
<th>Action</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>New branches</td>
<td>Do not create plan branches (default)</td>
<td>Bamboo does not create new plan branches automatically when new branches are detected in the primary source repository.</td>
<td>Independently from the automatic branch management settings, you can always create branches manually.</td>
</tr>
<tr>
<td></td>
<td>Create plan branches for all new branches</td>
<td>Bamboo creates a plan branch for each new branch detected in the primary source repository.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Create plan branches for matching new branches</td>
<td>Bamboo creates a plan branch for each new branch detected in the primary source repository that matches the regular expression that you provided.</td>
<td></td>
</tr>
<tr>
<td>Deleted branches</td>
<td>Do not delete plan branches (default)</td>
<td>If a branch in the primary source repository was deleted, Bamboo does not automatically delete the corresponding plan branch.</td>
<td>If you selected <strong>Clean up plan branch automatically</strong> in the configuration on the branch level, the branch is disabled and deleted according to the daily cleanup rules, regardless of the automatic branch management settings. <strong>Clean up plan branch automatically</strong> is selected by default for manually created “Plan Branches”.</td>
</tr>
<tr>
<td></td>
<td>Delete branches after a period of time</td>
<td>If a branch in the primary source repository was deleted, Bamboo deletes the corresponding plan branch. The value must be higher than 0 and is specified in days. Plan branches are deleted at most once a day.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Delete branches with a daily cleanup</td>
<td>If a branch in the primary source repository was deleted, the corresponding plan branch is removed with a daily cleanup that happens daily at 3 AM (server time).</td>
<td></td>
</tr>
<tr>
<td>Inactive branches</td>
<td>Do not delete inactive plan branches (default)</td>
<td>If a branch in the primary source repository is inactive, Bamboo does not automatically delete the corresponding plan branch.</td>
<td></td>
</tr>
</tbody>
</table>
Delete plan branches after a period of inactivity

If a branch in the primary source repository is inactive, Bamboo deletes the corresponding plan branch if no commits are detected for the specified period. The value must be higher than 1 and is specified in days.

4. Click **Save** at the bottom of the view to apply the changes.

**Global settings - branch detection interval**

Once plan branching is enabled, Bamboo checks for new or deleted branches in the primary source code repository.

You can specify how often Bamboo checks for new branches in the primary source repository in the system settings. The default value is 300 seconds.

To configure the branch detection interval:

1. Open the Bamboo Administration view by clicking the cog icon and selecting a section from the list that opens.
2. In the **Bamboo Administration** view, scroll down the menu on the left to find the **System** section.
3. Click **General configuration**.
4. In **Global system configurations**, set the branch detection interval. Provide the value in seconds, the default value is 300.

**Manual branch management**

Use manual branching for all supported repository types. You may want to consider using automatic branch management for Git, Mercurial and Subversion repositories.

To manually create a branch of a plan:

1. Go to the **Plan Configuration** view: in the Plan summary view, click the **Actions** button and select **Configure plan**.
2. Click the **Branches** tab.
3. Click **Create plan branch** in the upper right of the view.
4. In the **Create plan branch** view, you can create branches in one of the following ways:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select from available VCS branches</td>
<td>Select one or more branches from the list of available VCS branches. At the bottom of the list of the branches you can select the <strong>Enable branches</strong> check box, which makes all selected branches available for building and change detection.</td>
</tr>
</tbody>
</table>
| Create plan branch manually | Provide:  
- a display name (required) - overrides the VCS branch name  
- a branch description - a meaningful description of the branch  
- VCS branch name - the name of the branch in the VCS repository  
You can select the **Enable branches** check box, which makes the new branch available for building and change detection. Click **Auto-detect VCS** branches to go back to the list of available VCS branches. |

5. Click **Save**.

**Integrating branches with Jira applications**

Check **Create Remote Links from Jira Issues** to have the plan branch automatically linked, using an issue key in the branch name.

When a developer begins working on a feature described in a Jira application issue, they use Git or Mercurial to branch the repository. If they use the issue key as part of the VCS branch name, Bamboo will detect the issue key and automatically link the new branch to the issue:

- The Jira application issue key needs to be in the name of the branch – ‘jb-BDEV-790’ and ‘BDEV-769 1’ are valid forms.
- The link shows up right under the breadcrumb on the Build Result Summary for the plan branch, and on the issue too.

To use Jira applications Feature Branching, Bamboo needs an application link to the Jira application server.
Branch notifications

You can get build notifications from branch plans just as you do for master plans.

To specify how notifications are sent by all branches created from a plan, go to the Branches tab for the plan's configuration and choose one of the following options:

- Notify committers and people who have favorited this branch.
- Use the plan's notification settings.
- Notifications should not be sent for this branch.

You can override how notifications are sent from a particular branch plan, if necessary, by going to the Notifications tab on the Plan Branch configuration.

See Configuring notifications for a plan and its jobs for information about plan notifications.

Branch dependencies

You can use build dependencies for plan branches in a similar way to that for plans: a branch plan is triggered only when another branch plan has been successfully built. This can be used to ensure that breaking source code changes associated with one branch plan are detected before they can break the build of a dependent branch plan. Dependencies between master plans are maintained if their branch plans have the same name. See Setting up plan build dependencies for further information about dependencies.

Select Trigger Dependencies for Branches, on the Dependencies tab for the plan configuration, if you want plan branches to honor the build dependencies of their respective master plans.

Branch details configuration

Whether a plan branch is created automatically or manually, the master plan maintains the structure and configuration of it's branch plans. However, you can go to the configuration pages to override the following settings in a branch plan:

<table>
<thead>
<tr>
<th>Branch clean-up</th>
<th>On the Branch Details tab of the branch's configuration, you can specify that a plan branch is not cleaned up automatically.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Please note that 'Automatic Branch Clean-up' is supported for Mercurial, Git (Bamboo 4.1.1 and above) and Subversion (Bamboo 4.2.0 and above).</strong></td>
</tr>
<tr>
<td></td>
<td>By default, plan branches are deleted automatically after:</td>
</tr>
<tr>
<td></td>
<td>• 7 days after the branch was deleted in the primary source repository <strong>OR</strong></td>
</tr>
<tr>
<td></td>
<td>• 10 days of branch inactivity in the primary source repository</td>
</tr>
<tr>
<td></td>
<td>The values can be specified on the plan level.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Trigger type</th>
<th>On the Branch Details tab of the branch's configuration. See Triggering builds.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Note that you can only configure one trigger for a plan branch, and that this overrides all triggers that may be configured for the master plan.</td>
</tr>
</tbody>
</table>

| Merging | On the Branch Details tab of the branch's configuration. Described below. |
Source repository

On the Source Repository tab of the plan branch configuration. You can override the default repository settings of a plan on the branch level:

Notifications

On the Notifications tab of the branch's configuration. The options are:

- Notify committers and people who have favorited this branch.
- Use the plan's notification settings.
- Notifications should not be sent for this branch.

See Configuring notifications for a plan and its jobs for information about plan notifications.

Variables

On the Variables tab of the branch's configuration. See Defining plan variables.

Automatic branch merging

Bamboo provides 2 merging models if you choose to automate your branch merging:

- **Branch Updater** — a branch repo is kept up-to-date with changes to master. Note that changes on your master branch do not trigger branch builds.
- **Gatekeeper** — the default repo is only updated with changes in the branch that have built successfully.

The automatic branch merge strategy for the master plan can be overridden in an individual plan branch, if required. Automatic branch merging is not available for Subversion.
Branch updater

When to use

The Branch Updater should be used when you want to:

- Automatically merge changes from the team's master branch into your feature branch, after a successful build of the master and branch merge.
- Get notified when the changes on your feature branch are no longer compatible with the team's master branch.

Configuring

To have recent changes in another repo merged into your branch repo:

1. Go to the Branch Details tab of the branch plan's configuration pages.
   (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Branch Updater.
3. Use the Merge From list to choose the repo from which changes should be merged with your feature branch.
4. Select Push on only if you want those changes merged back into your branch once the build completes successfully.
5. Click Save.

Change detection is available only for the branch you're currently working on.
Gatekeeper

**When to use**

The Gatekeeper should be used when you want to:

- Automatically merge your feature branch back into the team's master branch, after a successful build of the merged changes from both branches.
- Get notified when a build of combined changes from both branches fails, preventing the feature branch from being merged back into the team's master branch.

**Configuring**

To have your successfully built changes pushed to another repo:

1. Go to the **Branch Details** tab of the branch plan's configuration pages.
   (Click on the branch icon beside a plan name on the All Plans tab, then choose **Actions > Configure Branch**.)
2. Under 'Merging' select **Branch Merging Enabled**, and then click **Gate Keeper**.
3. Use the **Checkout** list to choose the repo with which to merge your changes (and to which changes should be pushed).
4. Select **Push on** only if you want your changes pushed to the other repo once the build completes successfully,
5. Click **Save**.

**Limitations with plan branches**

The following limitations apply to using automated plan branching and merging:

<table>
<thead>
<tr>
<th>Action</th>
<th>Limitations</th>
</tr>
</thead>
</table>

Created by Atlassian in 2018. Licensed under a [Creative Commons Attribution 2.5 Australia License](https://creativecommons.org/licenses/by/2.5/au/).
Auto plan branching

- Can only be used with Git, Mercurial and Subversion repositories. For other repository types, use manual branching.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)

Manual plan branching

- Can be used for all repository types supported by Bamboo.

Auto branch merging

- Can only be used with Git and Mercurial repositories.
- Can only be used with branches that were configured in Bamboo.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)
- Requires Git version 1.8.1.5 or above as capability in Bamboo.

**Bamboo Branch status**

With Bamboo you can view and manage your plan branch assignments on a single page.

Getting to the Branch status dashboard

You can find the page in the top menu, in **Build > Branch status**:

You can also find a link to the **Branch status** page in some other places, like screens with the details of builds or plans:

Using the Branch status dashboard

Here are the most important things that you need to know about the Branch status dashboard.

**Picking a repository and a VCS branch**

To start working with branch statuses, you must specify a repository and a VCS branch. You can select it from a list or start typing to search by name.

The dashboard works for all linked repositories that support branches:

- Git
- Mercurial
- SVN
- Bitbucket Cloud
- Bitbucket Server / Stash
- Github

We've added a small **Copy** button next to the selected branch name - it copies the name of the branch in case you need to share it.
Viewing build plans assigned to a VCS branch

Once you pick a repository and a VCS branch, you'll probably see a list of plans that build the branch:

If the information about the commits is available to Bamboo, you can see the number of commits next to the build status:

Click the number to display the details of the commits:

It might happen that there aren't any build plans assigned to the VCS branch that you selected. You can associate the branch with a plan directly from the Branch status page (see Managing plan branches below).

Managing plan branches

You can manage assignments between plan branches and VCS branches directly from the Branch status page.

Adding a build plan to a VCS branch

On top of the list of existing plans (or on top of the empty list if there aren't any plans yet), you can find the search field and the Add button:
To assign a build plan to the selected VCS branch, click within the search field and either pick a build plan from a list or start typing to search:

Click **Add** to save the assignment.

Managing existing build plans

Once you've specified some plans that will build your branch, you can see them in the list on the Branch status page. Next to each plan, there's a small Actions menu that allows you to run, edit, or remove build plans assigned to a VCS branch:

---

Branches wallboard

The branches wallboard displays the status of all the branches and the plan that the branches belong to. The plan's own status always appears first. Plans shown as grey are disabled.

To display the branches wallboard:

1. Go to the Plan Summary for the plan that has branches you want to display.
2. Choose Actions → Branch Wallboard.

---

Tools such as Git and Mercurial encourage a practice called feature branching, where a developer can use a new branch to work in isolation from his or her team members before merging their changes back into main line development.
With plan branches in Bamboo:

- Any new branch created in the repository can be automatically built and tested using the same build configuration as that of the parent plan.
- Any branches deleted from the repository can be deleted automatically from Bamboo according to the settings.
- You have the flexibility to individually configure branch plans, by overriding the parent plan, if required.
- Optionally, changes from the feature branch can be automatically merged back to the "master" (e.g. trunk, default or mainline branch) when the build succeeds.

You can customize how Bamboo manages branches on the system, plan, and branch levels.

Managing plan branches in Bamboo

You can create plan branches manually or automatically. The branch configuration can be provided on the plan level and customized on the branch level. The settings provided in the branch configuration override the settings provided for the plan.

Use the Branch status page for quick access to plan branch information.

You can access the list of all branches in a plan from different places. For example, you can click the Branch icon next to the plan name in the Build Dashboard view:

![Branch icon in Build Dashboard](image)

You can also access the branch list from the Plan summary view:
Subversion branches location

This section is displayed only for plans that use a Subversion source repository. Bamboo assumes that your Subversion repository structure follows the convention for branches, and automatically calculates the branch root URL.

For example, for the fastBuild repo with this URL: https://svn.mycompany.com/svn/fastBuild/trunk, Bamboo will expect that branches will be created at this location: https://svn.mycompany.com/svn/fastBuild/branches.

If your Subversion repository structure follows a different convention, you can specify where repository branches will be created by selecting Change subversion branches URL.

Automatic branch management

Plan branches can be created and deleted automatically based on the updates in the primary source repository. Automatic branch management is available for Git, Mercurial, and Subversion. For other repository types, you can use manual branching. You can override the default settings for a branch, such as values of the variables.

By default, automatic branch management is:

- disabled for branches that you create manually
- enabled for branches that are created automatically

You can specify how often Bamboo checks the primary source repository for new or deleted branches in the general branch settings.

You can override the branch deletion settings in the branch details configuration view.

To hand over the branch management to Bamboo:

1. Go to the Plan Configuration view: in the Plan summary view, click the Actions button and select Configure plan
2. Click the Branches tab
3. In the Automatic branch management section, configure the following:

<table>
<thead>
<tr>
<th>Primary source repository branches</th>
<th>Action</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>New branches</td>
<td>Do not create plan branches (default)</td>
<td>Bamboo does not create new plan branches automatically when new branches are detected in the primary source repository.</td>
<td>Independently from the automatic branch management settings, you can always create branches manually.</td>
</tr>
<tr>
<td></td>
<td>Create plan branches for all new branches</td>
<td>Bamboo creates a plan branch for each new branch detected in the primary source repository.</td>
<td></td>
</tr>
<tr>
<td>Create plan branches for matching new branches</td>
<td>Bamboo creates a plan branch for each new branch detected in the primary source repository that matches the regular expression that you provided.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Deleted branches</td>
<td>Do not delete plan branches (default)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>If a branch in the primary source repository was deleted, Bamboo does not automatically delete the corresponding plan branch.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Delete branches after a period of time</td>
<td>If a branch in the primary source repository was deleted, Bamboo deletes the corresponding plan branch. The value must be higher than 0 and is specified in days. Plan branches are deleted at most once a day.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Delete branches with a daily cleanup</td>
<td>If a branch in the primary source repository was deleted, the corresponding plan branch is removed with a daily cleanup that happens daily at 3 AM (server time).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Inactive branches</td>
<td>Do not delete inactive plan branches (default)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>If a branch in the primary source repository is inactive, Bamboo does not automatically delete the corresponding plan branch.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Delete plan branches after a period of inactivity</td>
<td>If a branch in the primary source repository is inactive, Bamboo deletes the corresponding plan branch if no commits are detected for the specified period. The value must be higher than 1 and is specified in days.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

4. Click **Save** at the bottom of the view to apply the changes.

**Global settings - branch detection interval**

Once plan branching is enabled, Bamboo checks for new or deleted branches in the primary source code repository.

You can specify how often Bamboo checks for new branches in the primary source repository in the system settings. The default value is 300 seconds.

To configure the branch detection interval:

1. Open the Bamboo Administration view by clicking the cog icon and selecting a section from the list that opens.
2. In the **Bamboo Administration** view, scroll down the menu on the left to find the **System** section.
3. Click **General configuration**.
4. In **Global system configurations**, set the branch detection interval. Provide the value in seconds, the default value is 300.

**Manual branch management**

Use manual branching for all supported repository types. You may want to consider using automatic branch management for Git, Mercurial and Subversion repositories.

To manually create a branch of a plan:

1. Go to the **Plan Configuration** view: in the Plan summary view, click the **Actions** button and select **Configure plan**.
2. Click the **Branches** tab.
3. Click **Create plan branch** in the upper right of the view.
4. In the **Create plan branch** view, you can create branches in one of the following ways:
<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select from available VCS branches</td>
<td>Select one or more branches from the list of available VCS branches. At the bottom of the list of the branches you can select the <strong>Enable branches</strong> check box, which makes all selected branches available for building and change detection.</td>
</tr>
</tbody>
</table>
| Create plan branch manually | Provide:  
  - a display name (required) - overrides the VCS branch name  
  - a branch description - a meaningful description of the branch  
  - VCS branch name - the name of the branch in the VCS repository  
You can select the **Enable branches** check box, which makes the new branch available for building and change detection. Click **Auto-detect VCS branches** to go back to the list of available VCS branches. |

5. Click **Save**.

**Integrating branches with Jira applications**

Check **Create Remote Links from Jira Issues** to have the plan branch automatically linked, using an issue key in the branch name. When a developer begins working on a feature described in a Jira application issue, they use Git or Mercurial to branch the repository. If they use the issue key as part of the VCS branch name, Bamboo will detect the issue key and automatically link the new branch to the issue:

- The Jira application issue key needs to be in the name of the branch – ‘jb-BDEV-790’ and ‘BDEV-769 1’ are valid forms.
- The link shows up right under the breadcrumb on the Build Result Summary for the plan branch, and on the issue too.

To use Jira applications Feature Branching, Bamboo needs an application link to the Jira application server.

**Branch notifications**

You can get build notifications from branch plans just as you do for master plans.

To specify how notifications are sent by all branches created from a plan, go to the **Branches** tab for the plan's configuration and choose one of the following options:

- Notify committers and people who have favorited this branch.
- Use the plan's notification settings.
- Notifications should not be sent for this branch.

You can override how notifications are sent from a particular branch plan, if necessary, by going to the **Notifications** tab on the Plan Branch configuration.

See [Configuring notifications for a plan and its jobs](#) for information about plan notifications.

**Branch dependencies**

You can use build dependencies for plan branches in a similar way to that for plans: a branch plan is triggered only when another branch...
plan has been successfully built. This can be used to ensure that breaking source code changes associated with one branch plan are detected before they can break the build of a dependent branch plan. Dependencies between master plans are maintained if their branch plans have the same name. See Setting up plan build dependencies for further information about dependencies.

Select Trigger Dependencies for Branches, on the Dependencies tab for the plan configuration, if you want plan branches to honor the build dependencies of their respective master plans.

**Branch details configuration**

Whether a plan branch is created automatically or manually, the master plan maintains the structure and configuration of it’s branch plans. However, you can go to the configuration pages to override the following settings in a branch plan:

<table>
<thead>
<tr>
<th>Branch clean-up</th>
<th>On the Branch Details tab of the branch’s configuration, you can specify that a plan branch is not cleaned up automatically.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Please note that ‘Automatic Branch Clean-up’ is supported for Mercurial, Git (Bamboo 4.1.1 and above) and Subversion (Bamboo 4.2.0 and above).</td>
<td></td>
</tr>
<tr>
<td>By default, plan branches are deleted automatically after:</td>
<td></td>
</tr>
<tr>
<td>• 7 days after the branch was deleted in the primary source repository OR</td>
<td></td>
</tr>
<tr>
<td>• 10 days of branch inactivity in the primary source repository</td>
<td></td>
</tr>
<tr>
<td>The values can be specified on the plan level.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Trigger type</th>
<th>On the Branch Details tab of the branch’s configuration. See Triggering builds.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note that you can only configure one trigger for a plan branch, and that this overrides all triggers that may be configured for the master plan.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Merging</th>
<th>On the Branch Details tab of the branch’s configuration. Described below.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Source repository</th>
<th>On the Source Repository tab of the branch configuration. You can override the default repository settings of a plan on the branch level:</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Notifications</th>
<th>On the Notifications tab of the branch’s configuration. The options are:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Notify committers and people who have favorited this branch.</td>
<td></td>
</tr>
<tr>
<td>• Use the plan’s notification settings.</td>
<td></td>
</tr>
<tr>
<td>• Notifications should not be sent for this branch.</td>
<td></td>
</tr>
<tr>
<td>See Configuring notifications for a plan and its jobs for information about plan notifications.</td>
<td></td>
</tr>
</tbody>
</table>

| Variables | On the Variables tab of the branch’s configuration. See Defining plan variables. |

**Automatic branch merging**

Bamboo provides 2 merging models if you choose to automate your branch merging:

- **Branch Updater** — a branch repo is kept up-to-date with changes to master. Note that changes on your master branch do not trigger branch builds.
- **Gatekeeper** — the default repo is only updated with changes in the branch that have built successfully.

The automatic branch merge strategy for the master plan can be overridden in an individual plan branch, if required. Automatic branch merging is not available for Subversion.
Branch updater

When to use

The Branch Updater should be used when you want to:

- Automatically merge changes from the team's master branch into your feature branch, after a successful build of the master branch.
- Get notified when the changes on your feature branch are no longer compatible with the team's master branch.

Configuring

To have recent changes in another repo merged into your branch repo:

1. Go to the Branch Details tab of the branch plan's configuration pages.
   (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Branch Updater.
3. Use the Merge From list to choose the repo from which changes should be merged with your feature branch.
4. Select Push on only if you want those changes merged back into your branch once the build completes successfully.
5. Click Save.
Gatekeeper

When to use

The Gatekeeper should be used when you want to:

- Automatically merge your feature branch back into the team's master branch, after a successful build of the merged changes from both branches.
- Get notified when a build of combined changes from both branches fails, preventing the feature branch from being merged back into the team's master branch.

Configuring

To have your successfully built changes pushed to another repo:

1. Go to the Branch Details tab of the branch plan's configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Gate Keeper.
3. Use the Checkout list to choose the repo with which to merge your changes (and to which changes should be pushed).
4. Select Push on only if you want your changes pushed to the other repo once the build completes successfully.
5. Click Save.

Limitations with plan branches

The following limitations apply to using automated plan branching and merging:

<table>
<thead>
<tr>
<th>Action</th>
<th>Limitations</th>
</tr>
</thead>
</table>
### Auto plan branching
- Can only be used with Git, Mercurial and Subversion repositories. For other repository types, use manual branching.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)

### Manual plan branching
- Can be used for all repository types supported by Bamboo.

### Auto branch merging
- Can only be used with Git and Mercurial repositories.
- Can only be used with branches that were configured in Bamboo.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)
- Requires Git version 1.8.1.5 or above as capability in Bamboo.

---

**Bamboo Branch status**

With Bamboo you can view and manage your plan branch assignments on a single page.

![Branch status dashboard](image)

**Getting to the Branch status dashboard**

You can find the page in the top menu, in **Build > Branch status**:

![Build dashboard](image)

You can also find a link to the **Branch status** page in some other places, like screens with the details of builds or plans:

![Link to Branch status](image)

**Using the Branch status dashboard**

Here are the most important things that you need to know about the Branch status dashboard.

**Picking a repository and a VCS branch**

To start working with branch statuses, you must specify a repository and a VCS branch. You can select it from a list or start typing to search by name.

The dashboard works for all **linked repositories** that support branches:

- Git
- Mercurial
- SVN
- Bitbucket Cloud
- Bitbucket Server / Stash
- Github

We've added a small **Copy** button next to the selected branch name - it copies the name of the branch in case you need to share it.
Viewing build plans assigned to a VCS branch

Once you pick a repository and a VCS branch, you'll probably see a list of plans that build the branch:

If the information about the commits is available to Bamboo, you can see the number of commits next to the build status:

Click the number to display the details of the commits:

It might happen that there aren't any build plans assigned to the VCS branch that you selected. You can associate the branch with a plan directly from the Branch status page (see Managing plan branches below).

Managing plan branches

You can manage assignments between plan branches and VCS branches directly from the Branch status page.

Adding a build plan to a VCS branch

On top of the list of existing plans (or on top of the empty list if there aren't any plans yet), you can find the search field and the Add button:
To assign a build plan to the selected VCS branch, click within the search field and either pick a build plan from a list or start typing to search:

Click **Add** to save the assignment.

Managing existing build plans

Once you’ve specified some plans that will build your branch, you can see them in the list on the **Branch status** page. Next to each plan, there’s a small **Actions** menu that allows you to run, edit, or remove build plans assigned to a VCS branch:

**Branches wallboard**

The branches wallboard displays the status of all the branches and the plan that the branches belong to. The plan’s own status always appears first. Plans shown as grey are disabled.

**To display the branches wallboard:**

1. Go to the Plan Summary for the plan that has branches you want to display.
2. Choose **Actions** > **Branch Wallboard**.
Using plan branches v6.0

Plan branches are used to represent a branch in your version control repository, with the plan branch using the same build configuration as your plan.

Tools such as Git and Mercurial encourage a practice called feature branching, where a developer can use a new branch to work in isolation from his or her team members before merging their changes back into main line development.

With plan branches in Bamboo:

- Any new branch created in the repository can be automatically built and tested using the same build configuration as that of the parent plan.
- Any branches deleted from the repository can be deleted automatically from Bamboo according to the settings.
- You have the flexibility to individually configure branch plans, by overriding the parent plan, if required.
- Optionally, changes from the feature branch can be automatically merged back to the “master” (e.g. trunk, default or mainline branch) when the build succeeds.

You can customize how Bamboo manages branches on the system, plan, and branch levels.

Further reading:

- Atlassian Git Tutorial
- Feature branches explained

Managing plan branches in Bamboo

You can create plan branches manually or automatically. The branch configuration can be provided on the plan level and customized on the branch level. The settings provided in the branch configuration override the settings provided for the plan.

Use the Branch status page for quick access to plan branch information.

You can access the list of all branches in a plan from different places. For example, you can click the Branch icon.
next to the plan name in the **Build Dashboard** view:

You can also access the branch list from the **Plan summary** view:

Subversion branches location

This section is displayed only for plans that use a Subversion source repository. Bamboo assumes that your Subversion repository structure follows the convention for branches, and automatically calculates the branch root URL.

For example, for the fastBuild repo with this URL: https://svn.mycompany.com/svn/fastBuild/trunk, Bamboo will expect that branches will be created at this location: https://svn.mycompany.com/svn/fastBuild/branches.

If your Subversion repository structure follows a different convention, you can specify where repository branches will be created by selecting **Change subversion branches URL**.

Automatic branch management

Plan branches can be created and deleted automatically based on the updates in the primary source repository. Automatic branch management is available for Git, Mercurial, and Subversion. For other repository types, you can use manual branching. You can override the default settings for a branch, such as values of the variables.

By default, automatic branch management is:

- disabled for branches that you create manually
- enabled for branches that are created automatically

You can specify how often Bamboo checks the primary source repository for new or deleted branches in the **general branch settings**.

You can override the branch deletion settings in the **branch details configuration** view.
To hand over the branch management to Bamboo:

1. Go to the Plan Configuration view: in the Plan summary view, click the Actions button

   and select Configure plan

2. Click the Branches tab.

   a. Configure the following:

<table>
<thead>
<tr>
<th>Action</th>
<th>Primary source repository branches</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create plan branch</td>
<td>Manually</td>
<td>Bamboo doesn't create new plan branches automatically.</td>
<td>You can create branches manually.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When pull request is created</td>
<td>If a pull request is merged or declined, Bamboo will disable this plan branch. Note that this option is available for environment that provide support for pull requests. Currently, these are Bitbucket Server, and Bitbucket Cloud.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When new branch in repository is created</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>When new branch in repository is created and matches expression</td>
<td></td>
</tr>
<tr>
<td>Delete plan branch</td>
<td>After branch was deleted from repository</td>
<td>When a branch is deleted from the repository. Bamboo will wait for provided number of days before deleting the plan branch.</td>
<td>If you selected Clean up plan branch automatically in the configuration on the branch level, the branch is disabled and deleted according to the daily cleanup rules, regardless of the automatic branch management settings. Clean up plan branch automatically is selected by default for manually created &quot;Plan Branches&quot;.</td>
</tr>
<tr>
<td></td>
<td>After branch inactivity in repository</td>
<td>When a branch is inactive for provided number of days, Bamboo will delete the plan branch. If a branch in the primary source repository is inactive, Bamboo does not automatically delete the corresponding plan branch.</td>
<td></td>
</tr>
</tbody>
</table>

3. Click Save at the bottom of the view to apply the changes.

Global settings - branch detection interval

Once plan branching is enabled, Bamboo checks for new or deleted branches in the primary source code repository.

You can specify how often Bamboo checks for new branches in the primary source repository in the system settings. The default value is 300 seconds.

To configure the branch detection interval:

1. Open the Bamboo Administration view by clicking the cog icon

   and selecting a section from the list that opens.

2. In the Bamboo Administration view, scroll down the menu on the left to find the System section.

3. Click General configuration.

4. In Global system configurations, set the branch detection interval. Provide the value in seconds, the default value is 300.

Manual branch management

Use manual branching for all supported repository types. You may want to consider using automatic branch management for Git, Mercurial and Subversion repositories.

To manually create a branch of a plan:

1. Go to the Plan Configuration view: in the Plan summary view, click the Actions button
and select Configure plan
2. Click the Branches tab.
3. Click Create plan branch in the upper right of the view.
4. In the Create plan branch view, you can create branches in one of the following ways:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select from available VCS branches</td>
<td>Select one or more branches from the list of available VCS branches. At the bottom of the list of the branches you can select the Enable branches check box, which makes all selected branches available for building and change detection.</td>
</tr>
<tr>
<td>Create plan branch manually</td>
<td>Provide: • a display name (required) - overrides the VCS branch name • a branch description - a meaningful description of the branch • VCS branch name - the name of the branch in the VCS repository You can select the Enable branches check box, which makes the new branch available for building and change detection.</td>
</tr>
</tbody>
</table>

Click Save.

**Integrating branches with Jira applications**

Check Create Remote Links from Jira Issues to have the plan branch automatically linked, using an issue key in the branch name.

When a developer begins working on a feature described in a Jira application issue, they use Git or Mercurial to branch the repository. If they use the issue key as part of the VCS branch name, Bamboo will detect the issue key and automatically link the new branch to the issue:

- The Jira application issue key needs to be in the name of the branch – 'jb-BDEV-790' and 'BDEV-769 1' are valid forms.
- The link shows up right under the breadcrumb on the Build Result Summary for the plan branch, and on the issue too.

To use Jira applications Feature Branching, Bamboo needs an application link to the Jira application server.

**Branch notifications**

You can get build notifications from branch plans just as you do for master plans.

To specify how notifications are sent by all branches created from a plan, go to the Branches tab for the plan's configuration and choose one of the following options:

- Notify committers and people who have favorited this branch.
- Use the plan's notification settings.
- Notifications should not be sent for this branch.

You can override how notifications are sent from a particular branch plan, if necessary, by going to the Notifications tab on the Plan Branch configuration.

See Configuring notifications for a plan and its jobs for information about plan notifications.
**Branch dependencies**

You can use build dependencies for plan branches in a similar way to that for plans: a branch plan is triggered only when another branch plan has been successfully built. This can be used to ensure that breaking source code changes associated with one branch plan are detected before they can break the build of a dependent branch plan. Dependencies between master plans are maintained if their branch plans have the same name. See Setting up plan build dependencies for further information about dependencies.

Select **Trigger Dependencies for Branches**, on the **Dependencies** tab for the plan configuration, if you want plan branches to honor the build dependencies of their respective master plans.

**Branch details configuration**

Whether a plan branch is created automatically or manually, the master plan maintains the structure and configuration of it’s branch plans. However, you can go to the configuration pages to override the following settings in a branch plan:

| Branch clean-up | On the **Branch Details** tab of the branch’s configuration, you can specify that a plan branch is not cleaned up automatically.
|-----------------|---|
| Please note that 'Automatic Branch Clean-up' is supported for Mercurial, Git (Bamboo 4.1.1 and above) and Subversion (Bamboo 4.2.0 and above).
| By default, plan branches are deleted automatically after:
| • 7 days after the branch was deleted in the primary source repository OR
| • 10 days of branch inactivity in the primary source repository
| The values can be specified on the plan level. |

| Trigger type | On the **Branch Details** tab of the branch’s configuration. See **Triggering builds**.
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Note that you can only configure one trigger for a plan branch, and that this overrides all triggers that may be configured for the master plan.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Merging</th>
<th>On the <strong>Branch Details</strong> tab of the branch’s configuration. Described below.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Source repository</th>
<th>On the <strong>Source Repository</strong> tab of the plan branch configuration. You can override the default repository settings of a plan on the branch level:</th>
</tr>
</thead>
</table>

| Notifications | On the **Notifications** tab of the branch’s configuration. The options are:
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Notify committers and people who have favored this branch.</td>
<td>Use the plan’s notification settings.</td>
</tr>
<tr>
<td>Notifications should not be sent for this branch.</td>
<td></td>
</tr>
<tr>
<td>See <strong>Configuring notifications for a plan and its jobs</strong> for information about plan notifications.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Variables</th>
<th>On the <strong>Variables</strong> tab of the branch’s configuration. See <strong>Defining plan variables</strong>.</th>
</tr>
</thead>
</table>

**Automatic branch merging**

Bamboo provides 2 merging models if you choose to automate your branch merging:

- **Branch Updater** — a branch repo is kept up-to-date with changes to master. Note that changes on your master branch do not trigger branch builds.
- **Gatekeeper** — the default repo is only updated with changes in the branch that have built successfully.

The automatic branch merge strategy for the master plan can be overridden in an individual plan branch, if required. Automatic branch merging is not available for Subversion.
**Branch updater**

*When to use*

The Branch Updater should be used when you want to:

- Automatically merge changes from the team’s master branch into your feature branch, after a successful build of the master branch.
- Get notified when the changes on your feature branch are no longer compatible with the team’s master branch.

**Configuring**

To have recent changes in another repo merged into your branch repo:

1. Go to the Branch Details tab of the branch plan’s configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under ‘Merging’ select Branch Merging Enabled, and then click Branch Updater.
3. Use the Merge From list to choose the repo from which changes should be merged with your feature branch.
4. Select Push on only if you want those changes merged back into your branch once the build completes successfully.
5. Click Save.
**Gatekeeper**

*When to use*

The Gatekeeper should be used when you want to:

- Automatically merge your feature branch back into the team's master branch, after a successful build of the merged changes from both branches.
- Get notified when a build of combined changes from both branches fails, preventing the feature branch from being merged back into the team's master branch.

**Configuring**

To have your successfully built changes pushed to another repo:

1. Go to the Branch Details tab of the branch plan's configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Gate Keeper.
3. Use the Checkout list to choose the repo with which to merge your changes (and to which changes should be pushed).
4. Select Push on only if you want your changes pushed to the other repo once the build completes successfully.
5. Click Save.

**Limitations with plan branches**

The following limitations apply to using automated plan branching and merging:

<table>
<thead>
<tr>
<th>Action</th>
<th>Limitations</th>
</tr>
</thead>
</table>

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
<table>
<thead>
<tr>
<th>Auto plan branching</th>
<th>Can only be used with Git, Mercurial and Subversion repositories. For other repository types, use manual branching.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git. )</td>
</tr>
</tbody>
</table>

| Manual plan branching | Can be used for all repository types supported by Bamboo. |

<table>
<thead>
<tr>
<th>Auto branch merging</th>
<th>Can only be used with Git and Mercurial repositories.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Can only be used with branches that were configured in Bamboo.</td>
</tr>
<tr>
<td></td>
<td>Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git. )</td>
</tr>
<tr>
<td></td>
<td>Requires Git version 1.8.1.5 or above as capability in Bamboo.</td>
</tr>
</tbody>
</table>

**Branches wallboard**

The branches wallboard displays the status of all the branches and the plan that the branches belong to. The plan's own status always appears first. Plans shown as grey are disabled.

**To display the branches wallboard:**

1. Go to the Plan Summary for the plan that has branches you want to display.
2. Choose Actions > Branch Wallboard.

---

### Using plan branches v6.1

Plan branches are used to represent a branch in your version control repository, with the plan branch using the same build configuration as your plan.

Tools such as Git and Mercurial encourage a practice called feature branching, where a developer can use a new branch to work in isolation from his or her team members before merging their changes back into main line development.

With plan branches in Bamboo:

- Any new branch created in the repository can be automatically built and tested using the same build configuration as that of the parent plan.
- Any branches deleted from the repository can be deleted automatically from Bamboo according to the settings.
- You have the flexibility to individually configure branch plans, by overriding the parent plan, if required.
- Optionally, changes from the feature branch can be automatically merged back to the "master" (e.g. trunk, default or mainline branch) when the build succeeds.

You can customize how Bamboo manages branches on the system, plan, and branch levels.

**Further reading:**

- [Atlassian Git Tutorial](#)
- [Feature branches explained](#)
Managing plan branches in Bamboo

You can create plan branches manually or automatically. The branch configuration can be provided on the plan level and customized on the branch level. The settings provided in the branch configuration override the settings provided for the plan.

Use the Branch status page for quick access to plan branch information.

You can access the list of all branches in a plan from different places. For example, you can click the Branch icon next to the plan name in the Build Dashboard view:

![Build Dashboard with Branch icon](image)

You can also access the branch list from the Plan summary view:
Subversion branches location

This section is displayed only for plans that use a Subversion source repository. Bamboo assumes that your Subversion repository structure follows the convention for branches, and automatically calculates the branch root URL.

For example, for the `fastBuild` repo with this URL: https://svn.mycompany.com/svn/fastBuild/trunk, Bamboo will expect that branches will be created at this location: https://svn.mycompany.com/svn/fastBuild/branches.

If your Subversion repository structure follows a different convention, you can specify where repository branches will be created by selecting Change subversion branches URL.

Automatic branch management

Plan branches can be created and deleted automatically based on the updates in the primary source repository. Automatic branch management is available for Git, Mercurial, and Subversion. For other repository types, you can use manual branching. You can override the default settings for a branch, such as values of the variables.

By default, automatic branch management is:

- disabled for branches that you create manually
- enabled for branches that are created automatically

You can specify how often Bamboo checks the primary source repository for new or deleted branches in the general branch settings.

You can override the branch deletion settings in the branch details configuration view.

To hand over the branch management to Bamboo:

1. Go to the Plan Configuration view: in the Plan summary view, click the Actions button and select Configure plan.
2. Click the Branches tab.
   a. Configure the following:

<table>
<thead>
<tr>
<th>Action</th>
<th>Primary source repository branches</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
</table>

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
### Create plan branch

<table>
<thead>
<tr>
<th>Manually</th>
<th>Bamboo doesn't create new plan branches automatically. You can create branches manually.</th>
</tr>
</thead>
</table>

#### When pull request is created

Bamboo creates a plan branch automatically when a new pull request is created. If a pull request is merged or declined, Bamboo will disable this plan branch. Note that this option is available for environment that provide support for pull requests. Currently, these are Bitbucket Server, and Bitbucket Cloud.

#### When new branch in repository is created

Bamboo creates a plan branch for each new branch detected in the primary source repository.

#### When new branch in repository is created and matches expression

Bamboo creates a plan branch for each new branch detected in the primary source repository that matches the regular expression that you provided.

### Delete plan branch

After branch was deleted from repository

When a branch is deleted from the repository, Bamboo will wait for provided number of days before deleting the plan branch.

If you selected **Clean up plan branch automatically** in the configuration on the branch level, the branch is disabled and deleted according to the daily cleanup rules, regardless of the automatic branch management settings. **Clean up plan branch automatically** is selected by default for manually created “Plan Branches”.

After branch inactivity in repository

When a branch is inactive for provided number of days, Bamboo will delete the plan branch. If a branch in the primary source repository is inactive, Bamboo does not automatically delete the corresponding plan branch.

3. Click **Save** at the bottom of the view to apply the changes.

---

**Global settings - branch detection interval**

Once plan branching is enabled, Bamboo checks for new or deleted branches in the primary source code repository.

You can specify how often Bamboo checks for new branches in the primary source repository in the system settings. The default value is 300 seconds.

To configure the branch detection interval:

1. Open the Bamboo Administration view by clicking the cog icon and selecting a section from the list that opens.
2. In the **Bamboo Administration** view, scroll down the menu on the left to find the **System** section.
3. Click **General configuration**.
4. In **Global system configurations**, set the branch detection interval. Provide the value in seconds, the default value is 300.

---

**Manual branch management**

Use manual branching for all supported repository types. You may want to consider using **automatic branch management** for Git, Mercurial and Subversion repositories.

To manually create a branch of a plan:

1. Go to the **Plan Configuration** view: in the Plan summary view, click the **Actions** button and select **Configure plan**.
2. Click the **Branches** tab.
3. Click **Create plan branch** in the upper right of the view.
4. In the **Create plan branch** view, you can create branches in one of the following ways:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select from available VCS branches</td>
<td>Select one or more branches from the list of available VCS branches. At the bottom of the list of the branches you can select the <strong>Enable branches</strong> check box, which makes all selected branches available for building and change detection.</td>
</tr>
</tbody>
</table>
Create plan branch manually | Provide:
- a display name (required) - overrides the VCS branch name
- a branch description - a meaningful description of the branch
- VCS branch name - the name of the branch in the VCS repository

You can select the Enable branches check box, which makes the new branch available for building and change detection.

Click Auto-detect VCS branches to go back to the list of available VCS branches.

5. Click Save.

**Integrating branches with Jira applications**

Check Create Remote Links from Jira Issues to have the plan branch automatically linked, using an issue key in the branch name.

When a developer begins working on a feature described in a Jira application issue, they use Git or Mercurial to branch the repository. If they use the issue key as part of the VCS branch name, Bamboo will detect the issue key and automatically link the new branch to the issue:

- The Jira application issue key needs to be in the name of the branch – 'jb-BDEV-790' and 'BDEV-769 1' are valid forms.
- The link shows up right under the breadcrumb on the Build Result Summary for the plan branch, and on the issue too.

To use Jira applications Feature Branching, Bamboo needs an application link to the Jira application server.

**Branch notifications**

You can get build notifications from branch plans just as you do for master plans.

To specify how notifications are sent by all branches created from a plan, go to the Branches tab for the plan's configuration and choose one of the following options:

- Notify committers and people who have favorited this branch.
- Use the plan's notification settings.
- Notifications should not be sent for this branch.

You can override how notifications are sent from a particular branch plan, if necessary, by going to the Notifications tab on the Plan Branch configuration.

See Configuring notifications for a plan and its jobs for information about plan notifications.

**Branch dependencies**

You can use build dependencies for plan branches in a similar way to that for plans: a branch plan is triggered only when another branch plan has been successfully built. This can be used to ensure that breaking source code changes associated with one branch plan are detected before they can break the build of a dependent branch plan. Dependencies between master plans are maintained if their branch plans have the same name. See Setting up plan build dependencies for further information about dependencies.

Select Trigger Dependencies for Branches, on the Dependencies tab for the plan configuration, if you want plan branches to honor the build dependencies of their respective master plans.
**Branch details configuration**

Whether a plan branch is created automatically or manually, the master plan maintains the structure and configuration of its branch plans. However, you can go to the configuration pages to override the following settings in a branch plan:

**Branch clean-up**

On the **Branch Details** tab of the branch's configuration, you can specify that a plan branch is *not* cleaned up automatically.

*Please note that 'Automatic Branch Clean-up' is supported for Mercurial, Git (Bamboo 4.1.1 and above) and Subversion (Bamboo 4.2.0 and above).*

By default, plan branches are deleted automatically after:

- 7 days after the branch was deleted in the primary source repository
- OR
- 10 days of branch inactivity in the primary source repository

The values can be specified on the plan level.

**Trigger type**

On the **Branch Details** tab of the branch's configuration. See **Triggering builds**.

Note that you can only configure one trigger for a plan branch, and that this overrides all triggers that may be configured for the master plan.

**Merging**

On the **Branch Details** tab of the branch's configuration. Described below.

**Source repository**

On the **Source Repository** tab of the plan branch configuration. You can override the default repository settings of a plan on the branch level:

- **Source repository**
  - **Source repository**: Git
  - **Repository display name**: my_git_repo
  - **Branch**: The name of a branch or a tag that contains the source code.

- **Override the plan's default repository settings**
  - **Repository URL**: The URL of your Git repository.
  - **Authentication type**: None

- **Notifications**
  - **Notifications**
    - Notify committers and people who have favorited this branch.
    - Use the plan's notification settings.
    - Notifications should not be sent for this branch.

See **Configuring notifications for a plan and its jobs** for information about plan notifications.
Variables

On the Variables tab of the branch's configuration. See Defining plan variables.

Automatic branch merging

Bamboo provides 2 merging models if you choose to automate your branch merging:

- **Branch Updater** — a branch repo is kept up-to-date with changes to master. Note that changes on your master branch do not trigger branch builds.
- **Gatekeeper** — the default repo is only updated with changes in the branch that have built successfully.

The automatic branch merge strategy for the master plan can be overridden in an individual plan branch, if required. Automatic branch merging is not available for Subversion.
Branch updater

When to use

The Branch Updater should be used when you want to:

- Automatically merge changes from the team’s master branch into your feature branch, after a successful build of the master branch.
- Get notified when the changes on your feature branch are no longer compatible with the team’s master branch.

Configuring

To have recent changes in another repo merged into your branch repo:

1. Go to the Branch Details tab of the branch plan's configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Branch Updater.
3. Use the Merge From list to choose the repo from which changes should be merged with your feature branch.
4. Select Push on only if you want those changes merged back into your branch once the build completes successfully.
5. Click Save.
Gatekeeper

When to use

The Gatekeeper should be used when you want to:

- Automatically merge your feature branch back into the team’s master branch, after a successful build of the merged changes from both branches.
- Get notified when a build of combined changes from both branches fails, preventing the feature branch from being merged back into the team’s master branch.

Configuring

To have your successfully built changes pushed to another repo:

1. Go to the Branch Details tab of the branch plan’s configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under ‘Merging’ select Branch Merging Enabled, and then click Gate Keeper.
3. Use the Checkout list to choose the repo with which to merge your changes (and to which changes should be pushed).
4. Select Push on only if you want your changes pushed to the other repo once the build completes successfully.
5. Click Save.

Limitations with plan branches

The following limitations apply to using automated plan branching and merging:

<table>
<thead>
<tr>
<th>Action</th>
<th>Limitations</th>
</tr>
</thead>
</table>

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Auto plan branching

- Can only be used with Git, Mercurial and Subversion repositories. For other repository types, use manual branching.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)

Manual plan branching

- Can be used for all repository types supported by Bamboo.

Auto branch merging

- Can only be used with Git and Mercurial repositories.
- Can only be used with branches that were configured in Bamboo.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)

Branches wallboard

The branches wallboard displays the status of all the branches and the plan that the branches belong to. The plan’s own status always appears first. Plans shown as grey are disabled.

To display the branches wallboard:

1. Go to the Plan Summary for the plan that has branches you want to display.
2. Choose Actions > Branch Wallboard.

Using plan branches v6.2

Plan branches are used to represent a branch in your version control repository, with the plan branch using the same build configuration as your plan.

Tools such as Git and Mercurial encourage a practice called feature branching, where a developer can use a new branch to work in isolation from his or her team members before merging their changes back into main line development.

With plan branches in Bamboo:

- Any new branch created in the repository can be automatically built and tested using the same build configuration as that of the parent plan.
- Any branches deleted from the repository can be deleted automatically from Bamboo according to the settings.
- You have the flexibility to individually configure branch plans, by overriding the parent plan, if required.
- Optionally, changes from the feature branch can be automatically merged back to the “master” (e.g. trunk, default or mainline branch) when the build succeeds.

You can customize how Bamboo manages branches on the system, plan, and branch levels.

Further reading:

- Atlassian Git Tutorial
- Feature branches explained
Managing plan branches in Bamboo

You can create plan branches manually or automatically. The branch configuration can be provided on the plan level and customized on the branch level. The settings provided in the branch configuration override the settings provided for the plan.

Use the Branch status page for quick access to plan branch information.

You can access the list of all branches in a plan from different places. For example, you can click the Branch icon next to the plan name in the Build Dashboard view:

You can also access the branch list from the Plan summary view:
Subversion branches location

This section is displayed only for plans that use a Subversion source repository. Bamboo assumes that your Subversion repository structure follows the convention for branches, and automatically calculates the branch root URL.

For example, for the fastBuild repo with this URL: https://svn.mycompany.com/svn/fastBuild/trunk, Bamboo will expect that branches will be created at this location: https://svn.mycompany.com/svn/FastBuild/branches.

If your Subversion repository structure follows a different convention, you can specify where repository branches will be created by selecting Change subversion branches URL.

Automatic branch management

Plan branches can be created and deleted automatically based on the updates in the primary source repository. Automatic branch management is available for Git, Mercurial, and Subversion. For other repository types, you can use manual branching. You can override the default settings for a branch, such as values of the variables.

By default, automatic branch management is:

- disabled for branches that you create manually
- enabled for branches that are created automatically

You can specify how often Bamboo checks the primary source repository for new or deleted branches in the general branch settings.

You can override the branch deletion settings in the branch details configuration view.

To hand over the branch management to Bamboo:

1. Go to the Plan Configuration view: in the Plan summary view, click the Actions button and select Configure plan
2. Click the Branches tab.
   a. Configure the following:

<table>
<thead>
<tr>
<th>Action</th>
<th>Primary source repository branches</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
</table>

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Create plan branch

<table>
<thead>
<tr>
<th>Manual</th>
<th>Bamboo doesn't create new plan branches automatically. You can create branches manually.</th>
</tr>
</thead>
<tbody>
<tr>
<td>When pull request is created</td>
<td>Bamboo creates a plan branch automatically when a new pull request is created. If a pull request is merged or declined, Bamboo will disable this plan branch. Note that this option is available for environment that provide support for pull requests. Currently, these are Bitbucket Server, and Bitbucket Cloud.</td>
</tr>
<tr>
<td>When new branch in repository is created</td>
<td>Bamboo creates a plan branch for each new branch detected in the primary source repository.</td>
</tr>
<tr>
<td>When new branch in repository is created and matches expression</td>
<td>Bamboo creates a plan branch for each new branch detected in the primary source repository that matches the regular expression that you provided.</td>
</tr>
<tr>
<td>Delete plan branch</td>
<td>After branch was deleted from repository</td>
</tr>
<tr>
<td>Delete plan branch</td>
<td>After branch inactivity in repository</td>
</tr>
</tbody>
</table>

3. Click **Save** at the bottom of the view to apply the changes.

**Global settings - branch detection interval**

Once plan branching is enabled, Bamboo checks for new or deleted branches in the primary source code repository.

You can specify how often Bamboo checks for new branches in the primary source repository in the system settings. The default value is 300 seconds.

To configure the branch detection interval:

1. Open the Bamboo Administration view by clicking the cog icon

2. In the **Bamboo Administration** view, scroll down the menu on the left to find the **System** section.
3. Click **General configuration**.
4. In **Global system configurations**, set the branch detection interval. Provide the value in seconds, the default value is 300.

**Manual branch management**

Use manual branching for all supported repository types. You may want to consider using automatic branch management for Git, Mercurial and Subversion repositories.

To manually create a branch of a plan:

1. Go to the **Plan Configuration** view: in the Plan summary view, click the **Actions** button

2. Click the **Branches** tab.
3. Click **Create plan branch** in the upper right of the view.
4. In the **Create plan branch** view, you can create branches in one of the following ways:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select from available VCS branches</td>
<td>Select one or more branches from the list of available VCS branches. At the bottom of the list of the branches you can select the <strong>Enable branches</strong> check box, which makes all selected branches available for building and change detection.</td>
</tr>
</tbody>
</table>
Create plan branch manually | Provide:
- a display name (required) - overrides the VCS branch name
- a branch description - a meaningful description of the branch
- VCS branch name - the name of the branch in the VCS repository

You can select the Enable branches check box, which makes the new branch available for building and change detection.

Click Auto-detect VCS branches to go back to the list of available VCS branches.

5. Click Save.

**Integrating branches with Jira applications**

Check Create Remote Links from Jira Issues to have the plan branch automatically linked, using an issue key in the branch name.

When a developer begins working on a feature described in a Jira application issue, they use Git or Mercurial to branch the repository. If they use the issue key as part of the VCS branch name, Bamboo will detect the issue key and automatically link the new branch to the issue:

- The Jira application issue key needs to be in the name of the branch – ‘jb-BDEV-790’ and ‘ BDEV-769 1 ’ are valid forms.
- The link shows up right under the breadcrumb on the Build Result Summary for the plan branch, and on the issue too.

To use Jira applications Feature Branching, Bamboo needs an application link to the Jira application server.

**Branch notifications**

You can get build notifications from branch plans just as you do for master plans.

To specify how notifications are sent by all branches created from a plan, go to the Branches tab for the plan's configuration and choose one of the following options:

- Notify committers and people who have favorited this branch.
- Use the plan's notification settings.
- Notifications should not be sent for this branch.

You can override how notifications are sent from a particular branch plan, if necessary, by going to the Notifications tab on the Plan Branch configuration.

See Configuring notifications for a plan and its jobs for information about plan notifications.

**Branch dependencies**

You can use build dependencies for plan branches in a similar way to that for plans: a branch plan is triggered only when another branch plan has been successfully built. This can be used to ensure that breaking source code changes associated with one branch plan are detected before they can break the build of a dependent branch plan. Dependencies between master plans are maintained if their branch plans have the same name. See Setting up plan build dependencies for further information about dependencies.

Select Trigger Dependencies for Branches, on the Dependencies tab for the plan configuration, if you want plan branches to honor the build dependencies of their respective master plans.
**Branch details configuration**

Whether a plan branch is created automatically or manually, the master plan maintains the structure and configuration of it's branch plans. However, you can go to the configuration pages to override the following settings in a branch plan:

**Branch clean-up**

On the **Branch Details** tab of the branch's configuration, you can specify that a plan branch is *not* cleaned up automatically.

ℹ️ Please note that 'Automatic Branch Clean-up' is supported for Mercurial, Git (Bamboo 4.1.1 and above) and Subversion (Bamboo 4.2.0 and above).

By default, plan branches are deleted automatically after:

- 7 days after the branch was deleted in the primary source repository **OR**
- 10 days of branch inactivity in the primary source repository

The values can be specified on the plan level.

**Trigger type**

On the **Branch Details** tab of the branch’s configuration. See Triggering builds.

Note that you can only configure one trigger for a plan branch, and that this overrides all triggers that may be configured for the master plan.

**Merging**

On the **Branch Details** tab of the branch's configuration. Described below.

**Source repository**

On the **Source Repository** tab of the plan branch configuration. You can override the default repository settings of a plan on the branch level:

![Image of plan branch configuration](image)

- **Source repository**
  - **Source repository**: Git
  - **Repository display name**: my_git_repo
  - **Branch**: The name of a branch or a tag that contains the source code.

**Override the plan's default repository settings**

If you switch this option on, you can override the entire repository configuration. When this option is off, the settings shown below are inherited from plan's repository.

- **Repository URL**: The URL of your Git repository.
- **Authentication type**: None

**Notifications**

On the **Notifications** tab of the branch's configuration. The options are:

- Notify committers and people who have favorited this branch.
- Use the plan’s notification settings.
- Notifications should not be sent for this branch.

See Configuring notifications for a plan and its jobs for information about plan notifications.
Variables

On the Variables tab of the branch's configuration. See Defining plan variables.

Automatic branch merging

Bamboo provides 2 merging models if you choose to automate your branch merging:

- **Branch Updater** — a branch repo is kept up-to-date with changes to master. Note that changes on your master branch do not trigger branch builds.
- **Gatekeeper** — the default repo is only updated with changes in the branch that have built successfully.

The automatic branch merge strategy for the master plan can be overridden in an individual plan branch, if required. Automatic branch merging is not available for Subversion.
Branch updater

When to use

The Branch Updater should be used when you want to:

- Automatically merge changes from the team's master branch into your feature branch, after a successful build of the master branch.
- Get notified when the changes on your feature branch are no longer compatible with the team's master branch.

Configuring

To have recent changes in another repo merged into your branch repo:

1. Go to the Branch Details tab of the branch plan's configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Branch Updater.
3. Use the Merge From list to choose the repo from which changes should be merged with your feature branch.
4. Select Push on only if you want those changes merged back into your branch once the build completes successfully.
5. Click Save.
Gatekeeper

When to use

The Gatekeeper should be used when you want to:

- Automatically merge your feature branch back into the team's master branch, after a successful build of the merged changes from both branches.
- Get notified when a build of combined changes from both branches fails, preventing the feature branch from being merged back into the team's master branch.

Configuring

To have your successfully built changes pushed to another repo:

1. Go to the Branch Details tab of the branch plan's configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Gate Keeper.
3. Use the Checkout list to choose the repo with which to merge your changes (and to which changes should be pushed).
4. Select Push on only if you want your changes pushed to the other repo once the build completes successfully,
5. Click Save.

Limitations with plan branches

The following limitations apply to using automated plan branching and merging:

<table>
<thead>
<tr>
<th>Action</th>
<th>Limitations</th>
</tr>
</thead>
</table>

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Auto plan branching
- Can only be used with Git, Mercurial and Subversion repositories. For other repository types, use manual branching.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)

Manual plan branching
- Can be used for all repository types supported by Bamboo.

Auto branch merging
- Can only be used with Git and Mercurial repositories.
- Can only be used with branches that were configured in Bamboo.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)

Branches wallboard
The branches wallboard displays the status of all the branches and the plan that the branches belong to. The plan's own status always appears first. Plans shown as grey are disabled.

To display the branches wallboard:
1. Go to the Plan Summary for the plan that has branches you want to display.
2. Choose Actions > Branch Wallboard.

Using plan branches v6.3
Plan branches are used to represent a branch in your version control repository, with the plan branch using the same build configuration as your plan.

Tools such as Git and Mercurial encourage a practice called feature branching, where a developer can use a new branch to work in isolation from his or her team members before merging their changes back into main line development.

With plan branches in Bamboo:
- Any new branch created in the repository can be automatically built and tested using the same build configuration as that of the parent plan.
- Any branches deleted from the repository can be deleted automatically from Bamboo according to the settings.
- You have the flexibility to individually configure branch plans, by overriding the parent plan, if required.
- Optionally, changes from the feature branch can be automatically merged back to the "master" (e.g. trunk, default or mainline branch) when the build succeeds.

You can customize how Bamboo manages branches on the system, plan, and branch levels.

Further reading:
- Atlassian Git Tutorial
- Feature branches explained
Managing plan branches in Bamboo

You can create plan branches manually or automatically. The branch configuration can be provided on the plan level and customized on the branch level. The settings provided in the branch configuration override the settings provided for the plan.

Use the **Branch status** page for quick access to plan branch information.

You can access the list of all branches in a plan from different places. For example, you can click the **Branch** icon next to the plan name in the **Build Dashboard** view:

![Branch icon in Build Dashboard]

You can also access the branch list from the **Plan summary** view:
Subversion branches location

This section is displayed only for plans that use a Subversion source repository. Bamboo assumes that your Subversion repository structure follows the convention for branches, and automatically calculates the branch root URL.

For example, for the `fastBuild` repo with this URL: `https://svn.mycompany.com/svn/fastBuild/trunk`, Bamboo will expect that branches will be created at this location: `https://svn.mycompany.com/svn/fastBuild/branches`.

If your Subversion repository structure follows a different convention, you can specify where repository branches will be created by selecting `Change subversion branches URL`.

Automatic branch management

Plan branches can be created and deleted automatically based on the updates in the primary source repository. Automatic branch management is available for Git, Mercurial, and Subversion. For other repository types, you can use manual branching. You can override the default settings for a branch, such as values of the variables.

By default, automatic branch management is:

- disabled for branches that you create manually
- enabled for branches that are created automatically

You can specify how often Bamboo checks the primary source repository for new or deleted branches in the general branch settings.

You can override the branch deletion settings in the branch details configuration view.

To hand over the branch management to Bamboo:

1. Go to the Plan Configuration view: in the Plan summary view, click the Actions button and select Configure plan
2. Click the Branches tab.
   a. Configure the following:

<table>
<thead>
<tr>
<th>Action</th>
<th>Primary source repository branches</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
</table>

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Create plan branch | Manually | Bamboo doesn’t create new plan branches automatically. You can create branches manually.
---|---|---
When pull request is created | Bamboo creates a plan branch automatically when a new pull request is created. If a pull request is merged or declined, Bamboo will disable this plan branch. Note that this option is available for environment that provide support for pull requests. Currently, these are Bitbucket Server, and Bitbucket Cloud.
When new branch in repository is created | Bamboo creates a plan branch for each new branch detected in the primary source repository.
When new branch in repository is created and matches expression | Bamboo creates a plan branch for each new branch detected in the primary source repository that matches the regular expression that you provided.
Delete plan branch | After branch was deleted from repository | When a branch is deleted from the repository, Bamboo will wait for provided number of days before deleting the plan branch. If you selected Clean up plan branch automatically in the configuration on the branch level, the branch is disabled and deleted according to the daily cleanup rules, regardless of the automatic branch management settings. Clean up plan branch automatically is selected by default for manually created “Plan Branches”.
After branch inactivity in repository | When a branch is inactive for provided number of days, Bamboo will delete the plan branch. If a branch in the primary source repository is inactive, Bamboo does not automatically delete the corresponding plan branch.

3. Click **Save** at the bottom of the view to apply the changes.

**Global settings - branch detection interval**

Once plan branching is enabled, Bamboo checks for new or deleted branches in the primary source code repository.

You can specify how often Bamboo checks for new branches in the primary source repository in the system settings. The default value is 300 seconds.

To configure the branch detection interval:

1. Open the Bamboo Administration view by clicking the cog icon and selecting a section from the list that opens.
2. In the **Bamboo Administration** view, scroll down the menu on the left to find the **System** section.
3. Click **General configuration**.
4. In **Global system configurations**, set the branch detection interval. Provide the value in seconds, the default value is 300.

**Manual branch management**

Use manual branching for all supported repository types. You may want to consider using automatic branch management for Git, Mercurial and Subversion repositories.

To manually create a branch of a plan:

1. Go to the **Plan Configuration** view: in the Plan summary view, click the **Actions** button and select **Configure plan**.
2. Click the **Branches** tab.
3. Click **Create plan branch** in the upper right of the view.
4. In the **Create plan branch** view, you can create branches in one of the following ways:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select from available VCS branches</td>
<td>Select one or more branches from the list of available VCS branches. At the bottom of the list of the branches you can select the Enable branches check box, which makes all selected branches available for building and change detection.</td>
</tr>
</tbody>
</table>
Create plan branch manually

<table>
<thead>
<tr>
<th>Create plan branch manually</th>
<th>Provide:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• a display name (required) - overrides the VCS branch name</td>
</tr>
<tr>
<td></td>
<td>• a branch description - a meaningful description of the branch</td>
</tr>
<tr>
<td></td>
<td>• VCS branch name - the name of the branch in the VCS repository</td>
</tr>
<tr>
<td>You can select the Enable branches check box, which makes the new branch available for building and change detection.</td>
<td></td>
</tr>
</tbody>
</table>

Click Auto-detect VCS branches to go back to the list of available VCS branches.

5. Click **Save**.

**Integrating branches with Jira applications**

Check Create Remote Links from Jira Issues to have the plan branch automatically linked, using an issue key in the branch name.

When a developer begins working on a feature described in a Jira application issue, they use Git or Mercurial to branch the repository. If they use the issue key as part of the VCS branch name, Bamboo will detect the issue key and automatically link the new branch to the issue:

- The Jira application issue key needs to be in the name of the branch – 'jb-BDEV-790' and 'BDEV-769 1' are valid forms.
- The link shows up right under the breadcrumb on the Build Result Summary for the plan branch, and on the issue too.

To use Jira applications Feature Branching, Bamboo needs an application link to the Jira application server.

**Branch repositories**

Once the plan branch is created, automatically or manually, all repositories defined in the plan inherit settings from the master plan by default. The only exception is the default repository, which uses one of the following branches:

- branch selected by you during the manual creation of the plan,
- branch detected in VCS in case of automatically created plan.

You can change settings of all repositories defined in the plan branch in the Repositories tab. In this tab, simply put a desired branch name or enable the Change repository settings for this branch plan toggle if you need to modify more settings.

In the Branch summary tab the Repository branches section gives you a quick overview of repositories and branches configured in the plan branch. The Default repository settings changed flag indicates that this repository overrides more settings from the parent plan. The No branch support flag means that a given repository type does not support branches.

**Branch notifications**

You can get build notifications from branch plans just as you do for master plans.

To specify how notifications are sent by all branches created from a plan, go to the Branches tab for the plan's configuration and choose one of the following options:

- Notify committers and people who have favorited this branch.
- Use the plan's notification settings.
Notifications should not be sent for this branch.

You can override how notifications are sent from a particular branch plan, if necessary, by going to the Notifications tab on the Plan Branch configuration.

See Configuring notifications for a plan and its jobs for information about plan notifications.

Branch dependencies

You can use build dependencies for plan branches in a similar way to that for plans: a branch plan is triggered only when another branch plan has been successfully built. This can be used to ensure that breaking source code changes associated with one branch plan are detected before they can break the build of a dependent branch plan. Dependencies between master plans are maintained if their branch plans have the same name. See Setting up plan build dependencies for further information about dependencies.

Select Trigger Dependencies for Branches, on the Dependencies tab for the plan configuration, if you want plan branches to honor the build dependencies of their respective master plans.

Branch details configuration

Whether a plan branch is created automatically or manually, the master plan maintains the structure and configuration of it's branch plans. However, you can go to the configuration pages to override the following settings in a branch plan:

Branch clean-up

On the Branch Details tab of the branch's configuration, you can specify that a plan branch is not cleaned up automatically.

Please note that 'Automatic Branch Clean-up' is supported for Mercurial, Git (Bamboo 4.1.1 and above) and Subversion (Bamboo 4.2.0 and above).

By default, plan branches are deleted automatically after:

- 7 days after the branch was deleted in the primary source repository OR
- 10 days of branch inactivity in the primary source repository

The values can be specified on the plan level.

Trigger type

On the Branch Details tab of the branch's configuration. See Triggering builds.

Note that you can only configure one trigger for a plan branch, and that this overrides all triggers that may be configured for the master plan.

Merging

On the Branch Details tab of the branch's configuration. Described below.

Source repository

On the Source Repository tab of the plan branch configuration. You can override the default repository settings of a plan on the branch level:
Notifications

On the **Notifications** tab of the branch’s configuration. The options are:

- Notify committers and people who have favorited this branch.
- Use the plan’s notification settings.
- Notifications should not be sent for this branch.

See [Configuring notifications for a plan and its jobs](#) for information about plan notifications.

Variables

On the **Variables** tab of the branch’s configuration. See [Defining plan variables](#).

**Automatic branch merging**

Bamboo provides 2 merging models if you choose to automate your branch merging:

- **Branch Updater** — a branch repo is kept up-to-date with changes to master. Note that changes on your master branch do not trigger branch builds.
- **Gatekeeper** — the default repo is only updated with changes in the branch that have built successfully.

The automatic branch merge strategy for the master plan can be **overridden** in an individual plan branch, if required. Automatic branch merging is not available for Subversion.
Branch updater

When to use

The Branch Updater should be used when you want to:

- Automatically merge changes from the team's master branch into your feature branch, after a successful build of the master and branch merge.
- Get notified when the changes on your feature branch are no longer compatible with the team's master branch.

Configuring

To have recent changes in another repo merged into your branch repo:

1. Go to the Branch Details tab of the branch plan's configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Branch Updater.
3. Use the Merge From list to choose the repo from which changes should be merged with your feature branch.
4. Select Push on only if you want those changes merged back into your branch once the build completes successfully.
5. Click Save.

Change detection is available only for the branch you're currently working on.
Gatekeeper

**When to use**

The Gatekeeper should be used when you want to:

- Automatically merge your feature branch back into the team's master branch, after a successful build of the merged changes from both branches.
- Get notified when a build of combined changes from both branches fails, preventing the feature branch from being merged back into the team's master branch.

**Configuring**

To have your successfully built changes pushed to another repo:

1. Go to the Branch Details tab of the branch plan's configuration pages. (Click on the branch icon beside a plan name on the All Plans tab, then choose Actions > Configure Branch.)
2. Under 'Merging' select Branch Merging Enabled, and then click Gate Keeper.
3. Use the Checkout list to choose the repo with which to merge your changes (and to which changes should be pushed).
4. Select Push on only if you want your changes pushed to the other repo once the build completes successfully.
5. Click Save.

**Limitations with plan branches**

The following limitations apply to using automated plan branching and merging:

<table>
<thead>
<tr>
<th>Action</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Auto plan branching
- Can only be used with Git, Mercurial and Subversion repositories. For other repository types, use manual branching.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)

Manual plan branching
- Can be used for all repository types supported by Bamboo.

Auto branch merging
- Can only be used with Git and Mercurial repositories.
- Can only be used with branches that were configured in Bamboo.
- Cannot be used with the Git implementation embedded in Bamboo. (You need to have set up native Git.)

Branches wallboard

The branches wallboard displays the status of all the branches and the plan that the branches belong to. The plan's own status always appears first. Plans shown as grey are disabled.

To display the branches wallboard:
1. Go to the Plan Summary for the plan that has branches you want to display.
2. Choose Actions > Branch Wallboard.

Using the branch status page

With Bamboo you can view and manage your plan branch assignments on a single page.

On this page
- Getting to the branch status dashboard
- Using the branch status dashboard
  - Picking a repository and a VCS branch
  - Viewing build plans assigned to a VCS branch
  - Managing plan branches

Getting to the branch status dashboard

You can also find a link to the Branch status page in some other places, like screens with the details of builds or plans:
Using the branch status dashboard

Here are the most important things that you need to know about the Branch status dashboard.

**Picking a repository and a VCS branch**

To start working with branch statuses, you must specify a repository and a VCS branch. You can select it from a list or start typing to search by name.

The dashboard works for all linked repositories that support branches:

- Git
- Mercurial
- SVN
- Bitbucket Cloud
- Bitbucket Server / Stash
- Github

We've added a small Copy button next to the selected branch name - it copies the name of the branch in case you need to share it.

**Viewing build plans assigned to a VCS branch**

Once you pick a repository and a VCS branch, you'll see a list of plans that build the branch:

If the information about the commits is available to Bamboo, you can see the number of commits next to the build status:

Click the number to display the details of the commits:
It might happen that there aren't any build plans assigned to the VCS branch that you selected. You can associate the branch with a plan directly from the Branch status page (see Managing plan branches below).

Managing plan branches

You can manage assignments between plan branches and VCS branches directly from the Branch status page.

Adding a build plan to a VCS branch

On top of the list of existing plans (or on top of the empty list if there aren't any plans yet), you can find the search field and the Add button:

To assign a build plan to the selected VCS branch, click within the search field and either pick a build plan from a list or start typing to search:

Click Add to save the assignment.

Managing existing build plans

Once you've specified some plans that will build your branch, you can see them in the list on the Branch status page. Next to each plan, there's a small Actions menu that allows you to run, edit, or remove build plans assigned to a VCS branch:

Viewing pull requests

Starting from Bamboo 6.0, the branch status page also displays open pull requests outgoing from the selected VCS branch. Pull request information includes pull request name, target branch, and whether it's in conflicted state.
Currently, only the Bitbucket Server repository type is supported.

Using the branch status page v6.0

With Bamboo you can view and manage your plan branch assignments on a single page.

On this page
- Getting to the branch status dashboard
- Using the branch status dashboard
  - Picking a repository and a VCS branch
  - Viewing build plans assigned to a VCS branch
  - Managing plan branches

Getting to the branch status dashboard

You can find the page in the top menu, in Build > Branch status:

Using the branch status dashboard

Here are the most important things that you need to know about the Branch status dashboard.

Picking a repository and a VCS branch

To start working with branch statuses, you must specify a repository and a VCS branch. You can select it from a list or start typing to search by name.

The dashboard works for all linked repositories that support branches:
- Git
- Mercurial
- SVN
- Bitbucket Cloud
- Bitbucket Server / Stash
- Github

We’ve added a small Copy button next to the selected branch name - it copies the name of the branch in case you need to share it.

Viewing build plans assigned to a VCS branch
Once you pick a repository and a VCS branch, you'll see a list of plans that build the branch:

If the information about the commits is available to Bamboo, you can see the number of commits next to the build status:

Click the number to display the details of the commits:

It might happen that there aren't any build plans assigned to the VCS branch that you selected. You can associate the branch with a plan directly from the Branch status page (see Managing plan branches below).

Managing plan branches

You can manage assignments between plan branches and VCS branches directly from the Branch status page.

Adding a build plan to a VCS branch

On top of the list of existing plans (or on top of the empty list if there aren't any plans yet), you can find the search field and the Add button:

To assign a build plan to the selected VCS branch, click within the search field and either pick a build plan from a list or start typing to search:
Managing existing build plans

Viewing pull requests

Starting from Bamboo 6.0, the branch status page also displays open pull requests outgoing from the selected VCS branch. Pull request information includes pull request name, target branch, and whether it's in conflicted state.

Currently, only the Bitbucket Server repository type is supported.

Managing plans

A plan defines everything about your continuous integration build process in Bamboo. See Configuring plans for information about how to set up build plans.

You can also perform actions on one or more plans together, or make global settings that affect all plans on the Bamboo server.

See the following pages for information about managing your Bamboo plans:

- Configuring a plan’s permissions
- Disabling or deleting a plan
- Modifying multiple plans in bulk
- Moving plans to a different project
- Configuring concurrent builds
- Configuring the hanging build event
- Configuring the build queue timeout event
- Build monitoring

Configuring a plan’s permissions

This page describes how to change the permissions for a particular plan. For ongoing ease of management, we recommend that you grant permissions to groups rather than to individual users.

You need to have 'Admin' permission on the plan to edit its permissions.

Note that a Bamboo Admin can also set global permissions for access to Bamboo.

To change plan permissions:

1. Choose Build > All build plans from the Bamboo header, then click the name of the plan you want to edit.
2. Choose Actions > Configure plan.
3. Click the Permissions tab.
4. Use the ‘Grant permission to’ section to add users or groups for which you wish to set permissions.
5. Select (or clear) the check box for each permission that you wish to change for a user or group. See the table below for details.
6. Click Save.
Disabling or deleting a plan

Bamboo allows you to disable or delete plans that you don’t want to be built:

- **Disabling a plan** prevents it from being built. You can re-enable the plan, if you want to build it again.
  For example, if a plan’s latest build is broken and cannot be fixed quickly, you may want to disable it temporarily to stop the plan from being built.

- **Deleting a plan** removes it completely from your Bamboo system. You will need to recreate a new plan from scratch, if you want to build it again.
  For example, if a plan is no longer relevant, you may want to delete it.

---

**On this page:**
- Disable a plan
- Delete a plan

**Related pages:**
- Configuring plans
- Disabling or deleting a job
- Stopping an active build
- Exporting data for backup

---

**Permission types**

- **View** - User can view the plan in Bamboo, including its builds.
- **Edit** - User can view and edit the configuration of the plan and its jobs. This does not include the ability to change a user's permissions or its stages.
- **Build** - User can trigger a manual build on the plan, as well as suspending and resuming the job.
- **Clone** - User can clone the plan.
- **Admin** - User can administrate all components of the plan, including the stages and the plan’s permissions.

**Note:**

Users with the global 'admin' permission have all of the above permissions for this plan.
1. On the All Plans tab of the dashboard, click on the plan's name.
2. Choose Actions > Disable Plan.

You can also disable the plan using the Plan Enabled check box on the Plan Details tab of a plan's configuration pages.

Note that disabling a plan doesn't disable its branch plans.

**Delete a plan**

Deleting a plan deletes everything related to that plan, including the plan's configuration, all of the plan's job configurations and the plan's branch plans, job build results, artifacts, labels and comments:

- Deleting a plan also deletes its branch plans. Be careful!
- The 'Admin' global permission is required to delete a plan.
- A plan that is currently being built cannot be deleted. If you need to delete such a plan, stop the plan's build first. Refer to Stopping an active build for more information.
- Bamboo 'cleans up' everything related to deleted plans every two minutes. You'll have to wait at least that long if you want to reuse the key from a deleted plan.
- If you need to keep a permanent record of the job build results for your plan, see Exporting data for backup.

There are two ways to delete a plan:

- From the dashboard:
  1. On the All Plans tab of the dashboard, click on the plan to delete.
  2. Choose Actions > Configure Plan.
  3. Choose Actions > Delete Plan.
- In the Administration Console:
  1. Click the icon in the Bamboo header and choose Overview.
  2. Click Remove Plans (under 'Plans') in the left navigation column.
  3. Select the plan you wish to delete.
  4. Click Delete at the bottom of the list. You will be prompted to confirm the deletion.

**Modifying multiple plans in bulk**

Bulk actions allow you to make changes to multiple plans at once.

You need to be a Bamboo administrator to modify plans in bulk.

**To use bulk actions:**

1. Click the icon in the Bamboo header and choose Overview.
2. Click Bulk Action in the left-hand panel (under 'Plans').
3. Choose the required bulk action and follow the on-screen instructions to complete the 5 steps.

The following bulk actions are available:

- **Add new notification**
  See Configuring notifications for a plan and its jobs for further details.

- **Disable Plan**
  See Disabling or deleting a plan for further details.

- **Enable Plan**

- **Remove all notifications**
  See Configuring notifications for a plan and its jobs for further details.

- **Replace triggers**
  You can select a new trigger that will replace all existing triggers for the selected plans. This change affects all branches of the selected plans.

- **Run manual build**
  You have the option to disable dependencies when running the manual builds for the selected plans.

- **Update CVS module**
  See CVS documentation for further details.

- **Update CVS root and credentials**
  See CVS documentation for further details.

- **Update SVN credentials**
  See the Subversion documentation for further details.
Update SVN repository URL
See the Subversion documentation for further details.

Update web repository
See the Subversion, CVS or Perforce documentation for further details.

Modifying multiple plans in bulk v5.14

Bulk actions allow you to make changes to multiple plans at once.
You need to be a Bamboo administrator to modify plans in bulk.

To use bulk actions:

1. Click the 
   icon in the Bamboo header and choose Overview.
2. Click Bulk Action in the left-hand panel (under ‘Plans’).
3. Choose the required bulk action and follow the on-screen instructions to complete the 5 steps.

The following bulk actions are available:

<table>
<thead>
<tr>
<th>Bulk Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add new notification</td>
<td>See Configuring notifications for a plan and its jobs for further details.</td>
</tr>
<tr>
<td>Disable Plan</td>
<td>See Disabling or deleting a plan for further details.</td>

<td>See the Subversion documentation for further details.</td>
</tr>
<tr>
<td>Update SVN repository URL</td>
<td>See the Subversion documentation for further details.</td>
</tr>
<tr>
<td>Update web repository</td>
<td>See the Subversion, CVS or Perforce documentation for further details.</td>
</tr>
</tbody>
</table>

Modifying multiple plans in bulk v6.1

Bulk actions allow you to make changes to multiple plans at once.
You need to be a Bamboo administrator to modify plans in bulk.

To use bulk actions:

1. Click the 
   icon in the Bamboo header and choose Overview.
2. Click Bulk Action in the left-hand panel (under ‘Plans’).
3. Choose the required bulk action and follow the on-screen instructions to complete the 5 steps.

The following bulk actions are available:

Add new notification
See Configuring notifications for a plan and its jobs for further details.

Disable Plan
See Disabling or deleting a plan for further details.

Enable Plan

Remove all notifications
Replace triggers
You can select a new trigger that will replace all existing triggers for the selected plans. This change affects all branches of the selected plans.

Run manual build
You have the option to disable dependencies when running the manual builds for the selected plans.

Update CVS module
See CVS documentation for further details.

Update CVS root and credentials
See CVS documentation for further details.

Update SVN credentials
See the Subversion documentation for further details.

Update SVN repository URL
See the Subversion documentation for further details.

Update web repository
See the Subversion, CVS or Perforce documentation for further details.

Moving plans to a different project
Moving a plan to a different project involves changing the plan's project key (as well as possibly the plan name and plan key), which will also change the build key for all of the plan's build results.

Moving a plan does not affect the plan's configuration, nor any comments or labels that have been applied to job build results within the plan.

You need to be a Bamboo administrator to move a plan.

⚠️ Note that moving a plan will require Bamboo to re-index all its data, so your Bamboo system may run slowly for a few minutes.

Before you begin:
- We recommended that you back up your Bamboo build results before you move a plan. See Exporting data for backup for instructions.

To move a plan to a different project:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Move Plans (under 'Plans') in the left-hand panel.
3. Select either an existing project or New Project from the Destination Project list. For a new project, enter a new Project Name and a unique Project Key.
4. Select one or more plans to move.
5. Click Move to display the 'Configure New Plan Details' page (as shown in Screenshot 2 below).
6. Edit the new name and new key for each plan, if necessary. You may need to do this if the destination project already has a plan with the same plan name or key, or if you wish to change these.
7. Click Move.

Screenshot 1: 'Moving Plans - Select Plans'
Move build plan wizard

Select plans

You can move a plan to another project with this wizard. Simply select the plans you want to move and the Destination project. As names and keys may conflict, you'll then be asked to enter new names and keys for the plans. Note that because we are changing plan keys, this operation requires some slow operations (e.g. indexing of all Builds) and may take a few minutes.

<table>
<thead>
<tr>
<th>Destination project</th>
<th>New Project</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project name</td>
<td>A new project</td>
</tr>
<tr>
<td>Project key</td>
<td>NEWPROJ</td>
</tr>
</tbody>
</table>

This is the unique project key to identify a project. The key must contain only uppercase alphanumeric characters, e.g. "ITX".

Configure new plan details

Choose new build keys and build names

The following plans will be moved to project A new project. You can update the plan names and keys below.

<table>
<thead>
<tr>
<th>Original Project</th>
<th>Original Name</th>
<th>New Name</th>
<th>Original Key</th>
<th>New Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>+core+ Bamboo (BAM)</td>

Configuring concurrent builds

Bamboo's concurrent builds feature allows you to build a plan concurrently on several agents. You might find this useful if a plan is likely to be triggered again before the current build completes.

You can configure a default value for the maximum number of builds of a plan that your Bamboo server can run concurrently, using the Bamboo administration console. This value is a default – it can be overridden on the Miscellaneous tab of a plan's configuration.

You need to be a Bamboo administrator to configure concurrent builds.

To configure the number of concurrent builds of a plan allowed by Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Concurrent Builds in the left panel (under "Plans"), then click Enable.
3. Click Edit.
4. Edit the value for Default number of concurrent builds allowed.
5. Click Save.

Configuring the hanging build event

The hanging build event is thrown when Bamboo determines that a build has become unresponsive according to two criteria:
• Expected Build Time — defined as Build Time Multiplier x Average Build Time
  • Build Time Multiplier is a user-defined setting.
  • Average Build Time is calculated by Bamboo using an average of previous build times (in minutes).
• Log Quiet Time — the length of time (in minutes) between log entries for a build.

The Expected Build Time and Log Quiet Time must both be exceeded for Bamboo to throw a hanging build event.

This event is currently used by Bamboo to send notifications.

You can also disable build monitoring altogether so that the hanging build event never occurs.

On this page:
• Configure the hanging build event
• The check interval for hung builds

Related pages:
• Configuring notifications for a plan and its jobs
• Configuring the build queue timeout event
• Build monitoring
• Configuring tasks

Configure the hanging build event

You can change the criteria governing when a hanging build event is thrown.

Note, the hanging build criteria can also be set for a specific job, when specifying a job's builder. Job-level criteria will override the global criteria described on this page (including disabling this event).

To edit the hanging build event settings:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Build Monitoring (under ‘Plans’) in the left panel.
3. Click Edit and update the values for Build Time Multiplier and Log Quiet Time as required.
4. Click Save.

Screenshot: Editing the hanging build event settings

Build monitoring

You can configure the default settings for detecting hanging builds on this page. Hanging build detection can also be disabled altogether on this page. You can override these settings for individual plans in the executable configuration of each plan. Bamboo determines that a build has hung, if both of the criteria below are exceeded.

• expected build time - calculated as the average build time * build time multiplier
• log quiet time - the length of time Bamboo goes without receiving any log messages for that build

Default build monitoring criteria

<table>
<thead>
<tr>
<th>Build time multiplier</th>
<th>2.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log quiet time</td>
<td>30</td>
</tr>
</tbody>
</table>

Multiplier to be applied to the average build time (e.g. 2.5)
The length of time (in whole minutes) without logs being received (e.g. 10 minutes)

You can configure also default settings for detecting build waiting in build queue longer than specified time. Bamboo determines that build time has been exceeded if build waits in the queue longer specified timeout.

• build queue timeout - the length of time build waits in the queue before notification

Build queue timeout | 60 |
The length of time (in whole minutes) before queue timeout would be detected (e.g. 60 minutes)

Save Cancel

The check interval for hung builds

By default, Bamboo will check whether a hanging build event has been thrown every 60 seconds.

You can change this check interval by configuring the system property, bamboo.buildHangingMonitor.checkInterval. (This property is specified in seconds.)

Please read Starting Bamboo for instructions on how to configure the bamboo.buildHangingMonitor.checkInterval system property.

Configuring the build queue timeout event

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
The build queue timeout event is thrown when a build has been waiting in the build queue for longer than a specified period of time. This event is currently used by Bamboo to send notifications.

### Configuring the build queue timeout event

You can change the criteria governing when the build queue timeout event is thrown. You can also disable build monitoring altogether so that the build queue timeout event never occurs.

To edit the build queue timeout event settings:

1. Click the **icon in the Bamboo header and choose Overview.**
2. Click **Build Monitoring** (under “Plans”) in the left panel.
3. Click **Edit** and update the value for **Build Queue Timeout** as required.
4. Click **Save.**

#### Screenshot: Editing build queue timeout event settings

**Build monitoring**

You can configure the default settings for detecting hanging builds on this page. Hanging build detection can also be disabled altogether on this page. You can override these settings for individual plans in the executable configuration of each plan.

Bamboo determines that a build has hung if both of the criteria below are exceeded.

- **expected build time** - calculated as the average build time * build time multiplier
- **log quiet time** - the length of time Bamboo goes without receiving any log messages for that build

#### Default build monitoring criteria

<table>
<thead>
<tr>
<th>Build time multiplier</th>
<th>2.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Multiplier to be applied to the average build time (e.g. 2.5))</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Log quiet time</th>
<th>30</th>
</tr>
</thead>
<tbody>
<tr>
<td>(The length of time (in whole minutes) without logs being received (e.g. 19 minutes))</td>
<td></td>
</tr>
</tbody>
</table>

You can configure also default settings for detecting build waiting in build queue longer than specified time. Bamboo determines that build time has been exceeded if build waits in the queue longer specified timeout.

- **Build queue timeout** - the length of time build waits in the queue before notification

<table>
<thead>
<tr>
<th>Build queue timeout</th>
<th>60</th>
</tr>
</thead>
<tbody>
<tr>
<td>(The length of time (in whole minutes) before queue timeout would be detected (e.g. 60 minutes))</td>
<td></td>
</tr>
</tbody>
</table>

#### Disabling the build queue timeout event

You can disable the build queue timeout event by disabling build monitoring for your Bamboo installation. See **Build monitoring**.

Please note, you cannot disable the build queue timeout event without disabling all build monitoring features for your Bamboo installation.

#### The check interval for build queue timeouts

By default, Bamboo will check whether a build queue timeout event has been thrown every 60 seconds.

You can change this by configuring the system property, `bamboo.buildQueueMonitor.checkInterval`. (This property is specified in seconds.)

Please read **Starting Bamboo** for instructions on how to configure the `bamboo.buildQueueMonitor.checkInterval` system property.

Enabling build monitoring
Enabling build monitoring v6.4

Based on your settings Bamboo can define if a build is hanging or timed out. You can override these settings for individual plans in the executable configuration of each plan.

Disabling build monitoring

To disable build monitoring:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Build Monitoring in the left panel.
3. Click Disable. This will disable all build monitoring for your Bamboo installation, including the build hanging event and build queue timeout notifications. It is not possible to disable build monitoring features separately.

Screenshot: Disabling build monitoring

Build monitoring

Hanging build detection

You can configure the default settings for detecting hanging builds on this page. Hanging build detection can also be disabled altogether on this page. You can override these settings for individual plans in the executable configuration of each plan.

Bamboo determines that a build has hung, if both of the criteria below are exceeded:

- expected build time - calculated as the average build time * build time multiplier
- log quiet time - the length of time Bamboo goes without receiving any log messages for that build

Build queue timeout detection

You can configure also default settings for detecting build waiting in build queue longer than specified time. Bamboo determines that build time has been exceeded if build waits in the queue longer specified timeout.

- build queue timeout - the length of time build waits in the queue before notification

Default build monitoring criteria

Build time multiplier 2.5
Log quiet time 30
Build queue timeout 60

Edit Disable

Build monitoring v6.4

Based on your settings Bamboo can define if a build is hanging or timed out. You can override these settings for individual plans in the executable configuration of each plan.

To enable build monitoring

Build monitoring is enabled by default. To change its options, go to

> Overview > Build Monitoring.

Screenshot: Disabling build monitoring
To disable build monitoring:

1. Click the icon in the Bamboo header and choose Overview.
2. In the left-hand panel, click Build Monitoring.
3. Uncheck Allow Bamboo to detect hanging builds.

Disabling build monitoring v5.14

To disable build monitoring:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Build Monitoring in the left panel.
3. Click Disable. This will disable all build monitoring for your Bamboo installation, including the build hanging event and build queue timeout notifications. It is not possible to disable build monitoring features separately.

To configure artifact handlers, go to

> Artifact handlers.

Artifact handlers

Artifact handlers Bamboo administrators can control where artifacts produced by plans are stored. This can help to optimize the utilization of network bandwidth and filesystem space. You can activate each handler for shared and non-shared artifacts separately. Additionally, you can store artifacts in multiple locations. The default artifact handler selection is configured by Bamboo administrator but can be overridden in a plan's configuration by users that have administration permission on the plan.

To configure artifact handlers, go to

> Artifact handlers.

Types of handlers used by Bamboo:

AGENT-LOCAL ARTIFACT HANDLER

This handler stores the artifact on Bamboo's remote agent's filesystem. This handler does not publish artifacts to server (in other words, the artifacts will not be downloadable from result pages if remote or s3 handlers are not enabled). It can be used to save bandwidth when exchanging artifacts between builds & deployments running on the same agent or running on different agents that share common filesystem.

In the configuration you need to define the root directory in which all the artifacts will be saved.

BAMBOO REMOTE HANDLER

This handler makes artifacts accessible on Bamboo remote and elastic agents. It also allows remote agents to publish artifacts they produce when running builds.

AMAZON S3

Artifacts are stored at Amazon S3 and are downloadable from there. Amazon S3 that offers unlimited flexible storage capacity. For more information about S3, see the Amazon S3 page. You can use the AWS credentials provided in the Elastic Bamboo configuration or you can configure separate account. In either case, you need to provide a bucket name. You can also (optionally) provide a root path for all the artifacts, which can come in handy if you use the same S3 bucket for other purposes. Lastly, you can define a maximum number of files per artifact; if this threshold is exceeded the artifact is automatically zipped into a single file, which reduces the number of requests to S3 when uploading and downloading the artifacts and improves the efficiency of the whole process.

SERVER-LOCAL ARTIFACT HANDLER

This handler stores the artifacts directly on Bamboo server's filesystem. It is used by Bamboo server itself and by local agents.

### Configuring plans v6.1

A plan defines everything about your continuous integration build process in Bamboo.

A plan:

- Has a single stage, by default, but can be used to group jobs into multiple stages.
- Processes a series of one or more stages that are run sequentially using the same repository.
- Specifies the default repository.
- Specifies how the build is triggered, and the triggering dependencies between the plan and other plans in the project.
- Specifies notifications of build results.
- Specifies who has permission to view and configure the plan and its jobs.
- Provides for the definition of plan variables.

Every plan belongs to a project.

Projects and plans can only be configured by Bamboo administrators (see Creating a plan).

On this page:

- Navigate to a plan's configuration
- Configure a plan
- Exporting plan configuration to Bamboo Specs

Navigate to a plan's configuration

Choose Build > All build plans from the Bamboo header, then click the edit icon ( ) for the plan you want to edit.

The plan's configuration is found on several tabs. you can also view the configuration in the YAML format:

Configure a plan

1. Navigate to the plan's configuration pages as described above.
2. Click a tab to configure that aspect of your plan:

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plan details</td>
<td>A plan’s Project Key and Plan Key are not editable once the plan is created, however see Moving plans to a different project.</td>
</tr>
<tr>
<td>Stages</td>
<td>See Using stages in a plan.</td>
</tr>
<tr>
<td>Repositories</td>
<td>See Linking to source code repositories.</td>
</tr>
</tbody>
</table>
2. Triggers

See Triggering builds.

Branches

See Using plan branches.

Dependencies

See Setting up build dependencies.

Permissions

See Configuring a plan’s permissions.

Notifications

See Configuring notifications.

Variables

See Defining plan variables.

Miscellaneous

See Configuring expiry of a plan’s build results.

Audit log

A record of changes to the plan’s configuration. This feature is disabled by default. To enable it, please go to Administration > System > Audit Log.

Exporting plan configuration to Bamboo Specs

Bamboo instance administrators can export the plan configuration to Bamboo Specs in Plan configuration > Actions:

Configuring plans v5.14

A plan defines everything about your continuous integration build process in Bamboo.

A plan:

- Has a single stage, by default, but can be used to group jobs into multiple stages.
- Processes a series of one or more stages that are run sequentially using the same repository.

Exporting plan configuration to Bamboo Specs

Bamboo instance administrators can export the plan configuration to Bamboo Specs in Plan configuration > Actions:
Docker Pipelines

Docker Runner v6.4

With Docker Runner, you can run builds and deployments in a Docker container to isolate the build process from the environment it runs in. This increases the security of your environments by providing more strict control over resources the continuous integration (CI) process has access to. The isolation also helps with the reliability of your CI, by making sure that environment it runs in can be reliably recreated each time you run your builds.

If you want to use Docker images in your Bamboo builds, you can do that with Docker tasks. See Configuring the Docker task in Bamboo.

Enabling Docker Runner

Bamboo provides support for Docker for Mac, and Docker for Ubuntu in version 17 and later. Docker Runner can be enabled for jobs and deployment environments when:

- creating or editing jobs
- creating or editing deployment environments

Docker Runner is also fully supported with Bamboo Specs. See our Bamboo Specs reference guide.
Advanced Docker configuration

When editing a job or a deployment environment, you can also specify which directories from Bamboo agent should be mounted as additional volumes to the Docker container.

Isolate build
Jobs are normally run in the agent’s native operating system. To run your build in an isolated and controlled environment, you can do it with Docker.

- Volumes
Specify Bamboo agent's directories which will be mounted as data volumes in the Docker container.

Tip
Use `~` to provide a path to your home directory.

Requirements
Enabling Docker for a job or a deployment environment disables standard requirements which come from tasks. All the requirements
which come from tasks will be replaced with a single requirement for Docker.

Custom requirements, manually configured by users, will not be erased, and will still be used for agent matching.

.Docker Runner v6.5

With Docker Runner, you can run builds and deployments in a Docker container to isolate the build process from the environment it runs in. This increases the security of your environments by providing more strict control over resources the continuous integration (CI) process has access to. The isolation also helps with the reliability of your CI, by making sure that environment it runs in can be reliably recreated each time you run your builds.

If you want to use Docker images in your Bamboo builds, you can do that with Docker tasks. See Configuring the Docker task in Bamboo.

Enabling Docker Runner

Bamboo provides support for Docker for Mac, and Docker for Linux in version 17 and later. Docker Runner can be enabled for jobs and deployment environments when:

- creating or editing jobs
- creating or editing deployment environments

Docker Runner is also fully supported with Bamboo Specs. See our Bamboo Specs reference guide.
Advanced Docker configuration

When editing a job or a deployment environment, you can also specify which directories from Bamboo agent should be mounted as additional volumes to the Docker container.

**Isolate build**

Jobs are normally run in the agent environment. To run your build in an isolated and controlled environment, you can do it with Docker.

- Run this job in
  - Agent environment
  - Docker container

- **Docker image**: ubuntu:latest

**Volumes**

Specify Bamboo agent's directories which will be mounted as data volumes in the Docker container.

<table>
<thead>
<tr>
<th>Host directory</th>
<th>Container directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>$(bamboo.working.directory)</td>
<td>$(bamboo.working.directory)</td>
</tr>
<tr>
<td>$(bamboo.tmp.directory)</td>
<td>$(bamboo.tmp.directory)</td>
</tr>
</tbody>
</table>

- **Tip**: Use `~/` to provide a path to your home directory.

**Requirements**

Enabling Docker for a job or a deployment environment disables standard requirements which come from tasks. All the requirements which come from tasks will be replaced with a single requirement for Docker.

Custom requirements, manually configured by users, will not be erased, and will still be used for agent matching.

**Linking to source code repositories**

A key part of setting up your continuous integration build process is to specify the code repositories that Bamboo will work with. You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level, described below.

**Important changes to Linked Repositories that affect usage and permissions**

Linked repositories are now the preferred way to define and share repository configuration between plans in Bamboo. As a result, we've made two changes that you should be aware of:

- When users create plans, they are only given the option to **select** from Linked Repositories. This requires that users have the **Create plan** global permission.
Link a source code repository for all Bamboo plans

Linked repositories are available globally to all plans and jobs configured on the Bamboo server. Doing this can save you from having to reconfigure the source repositories in multiple places if these ever change - any changes to a linked repository are applied to every plan or job that uses that repository.

You need the 'Create plan' or 'Admin' global permission to configure linked repositories.

1. Click the 'cog' icon in the Bamboo header and then **Linked repositories**.
2. Click **Add repository**.
3. Select your repository type from the available menu options. For configuration details for a particular repository type, please refer to one of the following pages:
   - Bitbucket (for Bitbucket Cloud)
   - Stash (for Bitbucket Server)
   - Git
   - GitHub
   - Mercurial
   - Subversion
   - CVS
   - Perforce

If you need to use an unsupported type of repository, a number of third-party Source Repository plugin modules are available (e.g. the ClearCase plugin). You can also write a **Source Repository Module plugin** to enable Bamboo to connect to your repository.

Note that **shared source repositories** are no longer the preferred way to share repository configuration between plans. Use linked repositories instead!

Configure a repository for a plan

When you **create a new plan**, the source repository you specify becomes the default. It is used by the plan's 'Default Job' and can be used by other jobs added to this plan.

1. Navigate to the plan. See **Configuring plans** for instructions.
2. Choose **Actions > Configure plan**.
   - Click the **Repositories** tab to see all the repositories that have been added to the plan.
   - Click a repository name in the list to edit its configuration details.
   - Click **Add repository** to configure a repository to be used by the plan.

For configuration details for a particular repository type, please refer to one of the following pages:
   - Bitbucket (for Bitbucket Cloud)
   - Stash (for Bitbucket Server)
   - Git
   - GitHub
   - Mercurial
   - Subversion
   - CVS
   - Perforce

Please note that In the long term, **Atlassian plans to deprecate the repository configuration defined against the plan**. These configurations can be converted to **linked repositories** by clicking **Convert to linked repository** in each plan's repository configuration page.

Configure a repository for a job

You can specify additional repositories for a Bamboo plan to work with at the job level, perhaps for tasks in later stages of the build.

You add the Source Code Checkout task to a job to configure a particular repository for just that job. See **Checking out code** for details about configuring the Source Code Checkout task.

**Bitbucket Server**

Configure Bamboo to use a Bitbucket Server repository.

You can specify repositories at the following levels in Bamboo:
   - global – repositories are available to all plans in Bamboo.
   - plan – repositories are available to all jobs in the Bamboo plan.

In the long term, **Atlassian plans to deprecate the repository configuration defined against the plan**. These configurations can be converted to **linked repositories** by clicking **Convert to linked repository** in each plan's repository configuration page.
- Job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

When you link a repository hosted in Atlassian's Bitbucket Server with a build plan in Bamboo, then without any further configuration:

- Bamboo will automatically run a build when changes are pushed to the Bitbucket Server repository, without needing to configure polling.
- Bamboo will automatically update plan branches when a developer pushes a new branch to the repository (or deletes a branch).
- You can click through to Bitbucket Server to see the commit diff for all files that are part of the changeset.
- Bitbucket Server commits that are part of a build are displayed in Bamboo.
- Build results are notified to Bitbucket Server (and displayed for the associated commits and pull requests).

Bitbucket Server and Bamboo only need to have been connected by creating an application link. Repositories in Bitbucket Server are then made available in Bamboo, so it is easy for you to link your Bamboo plan to a Bitbucket Server repository.

When you create a plan that uses a Bitbucket Server source repository, Bamboo will automatically use the 'Bitbucket Server repository triggers the build when changes are committed' trigger option instead of using the 'polling the repository for changes' option. This reduces the load on the Bamboo and Bitbucket servers because Bamboo doesn't need to send poll requests (for each branch of each plan) to the Bitbucket server every 3 minutes (the default polling period). Instead, Bitbucket Server will trigger Bamboo whenever there is a push to the repository.

Configuration requirements

Navigate to the source repository settings for a plan or job, as described on Linking to source code repositories, then:

1. Either click Add Repository to add a new repository, or edit an existing repository configuration.
2. Choose Stash from the Repository host list.
3. Complete the required information:

<table>
<thead>
<tr>
<th>Display name</th>
<th>A name that identifies this repository within Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stash server</td>
<td>This menu will show all Bitbucket servers that have been linked to Bamboo via an application link.</td>
</tr>
<tr>
<td>Repository</td>
<td>The repository that will be built. This menu will show all repositories on the Bitbucket server that you have permissions to access.</td>
</tr>
<tr>
<td>Branch</td>
<td>Pick a branch if you want to check out code from a branch other than the default branch.</td>
</tr>
</tbody>
</table>

**Advanced options**

<table>
<thead>
<tr>
<th>Use shallow clones</th>
<th>Allows Bamboo to perform shallow clones (i.e. history truncated to a specified number of revisions). This should increase the speed of the initial code checkouts, however if your build depends on the full repository history, we recommend that you do not use this option. Shallow clones are enabled by default.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable repository caching on remote agents</td>
<td>Allow caching of repositories on remote agents to save bandwidth. Note that caches are always full clones of the source repository.</td>
</tr>

<td>Turns on more verbose logs from Git commands. Use this option if you encounter problems with Git in Bamboo.</td>
</tr>
<tr>
<td>Fetch whole repository</td>
<td>Fetches whole repository instead of only one selected branch.</td>
</tr>
</tbody>
</table>
### Enable LFS support

Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server. To use this option you must have the following:

- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

To learn more about Git LFS, see Git LFS tutorials.

### Mirror

Allows you to use mirror locations for storing your repository data instead of using remote location. Read more.

### Change detection options

<table>
<thead>
<tr>
<th>Change detection options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Enable Quiet Period</strong></td>
<td>Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.</td>
</tr>
<tr>
<td><strong>Include/Exclude Files</strong></td>
<td>Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use only the mentioned files for change detection (by default Bamboo checks all the files). In the same way, if you configure the Exclude option, Bamboo will not consider the excluded files when detecting changes. Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See this page for examples.</td>
</tr>
<tr>
<td><strong>Exclude changesets</strong></td>
<td>Enter a regular expression to match the commit messages for changesets that should not start a build.</td>
</tr>
</tbody>
</table>

### Web repository options

<table>
<thead>
<tr>
<th>Stash</th>
<th>Specify the following details for the repository:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server URL</td>
<td>– the URL of your Bitbucket Server instance (e.g. <a href="https://bitbucket.mycompany.com/">https://bitbucket.mycompany.com/</a>).</td>
</tr>
<tr>
<td>Slash Project Key</td>
<td>– the key of the project in Bitbucket Server (e.g. 'CONF').</td>
</tr>
<tr>
<td>Repository Name</td>
<td>– the name of the repository in Bitbucket Server (e.g. 'conf-dev')</td>
</tr>
</tbody>
</table>

See [Integrating Bamboo with Bitbucket Server](#) for more information.

**Bitbucket Server v5.14**

This page describes how to configure Bamboo to use a Bitbucket Server repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

When you link a repository hosted in Atlassian's Bitbucket Server with a build plan in Bamboo, then without any further configuration:

- Bamboo will automatically run a build when changes are pushed to the Bitbucket Server repository, without needing to configure polling.
- Bamboo will automatically update plan branches when a developer pushes a new branch to the repository (or deletes a branch).
- You can click through to Bitbucket Server to see the commit diff for all files that are part of the changeset.
- Bitbucket Server commits that are part of a build are displayed in Bamboo.
- Build results are notified to Bitbucket Server (and displayed for the associated commits and pull requests).

---

**On this page:**
- Configuration requirements

Bitbucket Server and Bamboo only need to have been connected by creating an application link. Repositories in Bitbucket Server are then
made available in Bamboo, so it is easy for you to link your Bamboo plan to a Bitbucket Server repository.

When you create a plan that uses a Bitbucket Server source repository, Bamboo will automatically use the 'Bitbucket Server repository triggers the build when changes are committed' trigger option instead of using the 'polling the repository for changes' option. This reduces the load on the Bamboo and Bitbucket servers because Bamboo doesn’t need to send poll requests (for each branch of each plan) to the Bitbucket server every 3 minutes (the default polling period). Instead, Bitbucket Server will trigger Bamboo whenever there is a push to the repository.

**Configuration requirements**

Navigate to the source repository settings for a plan or job, as described on Linking to source code repositories, then:

1. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
2. Choose **Stash** from the **Repository host** list.
3. Complete the required information:

<table>
<thead>
<tr>
<th>Display name</th>
<th>A name that identifies this repository within Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stash server</td>
<td>This menu will show all Bitbucket servers that have been linked to Bamboo via an application link.</td>
</tr>
<tr>
<td>Repository</td>
<td>The repository that will be built. This menu will show all repositories on the Bitbucket server that you have permissions to access.</td>
</tr>
<tr>
<td>Branch</td>
<td>Pick a branch if you want to check out code from a branch other than the default branch.</td>
</tr>
</tbody>
</table>

### Advanced options

- **Use shallow clones**
  - Allows Bamboo to perform shallow clones (i.e. history truncated to a specified number of revisions). This should increase the speed of the initial code checkouts, however if your build depends on the full repository history, we recommend that you do not use this option. Shallow clones are enabled by default.

- **Enable repository caching on remote agents**
  - Allow caching of repositories on remote agents to save bandwidth. Note that caches are always full clones of the source repository.

- **Use submodules**
  - Select to enable submodules support if these are defined for the repository. If native Git capability is not defined for agent submodules support will be disabled.

- **Command timeout**
  - This helps to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Git repository.

- **Verbose logs**
  - Turns on more verbose logs from Git commands. Use this option if you encounter problems with Git in Bamboo.

- **Fetch whole repository**
  - Fetches whole repository instead of only one selected branch.

- **Enable Quiet Period**
  - Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

- **Include/Exclude Files**
  - Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use **only** the mentioned files for change detection (by default Bamboo checks all the files). In the same way, if you configure the Exclude option, Bamboo will not consider the excluded files when detecting changes.

  Enter into **File Pattern** a **regular expression** to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See [this page](#) for examples.

- **Exclude changesets**
  - Enter a **regular expression** to match the commit messages for changesets that should not start a build.
Web repository

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

**Stash** – specify the following details for the repository:

- **Server URL** – the URL of your Bitbucket Server instance (e.g. 'https://bitbucket.mycompany.com').
- **Stash Project Key** – the key of the project in Bitbucket Server (e.g. 'CONF').
- **Repository Name** – the name of the repository in Bitbucket Server (e.g. 'conf-dev').

See [Integrating Bamboo with Bitbucket Server](#) for more information.

</tr>
</tbody>
</table>
Enable Quiet Period
Specifications a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use only the mentioned files for change detection (by default Bamboo checks all the files). In the same way, if you configure the Exclude option, Bamboo will not consider the excluded files when detecting changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See this page for examples.

Exclude changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Web repository options

Stash
Specify the following details for the repository:
- Server URL – the URL of your Bitbucket Server instance (e.g. https://bitbucket.mycompany.com/).
- Stash Project Key – the key of the project in Bitbucket Server (e.g. 'CONF').
- Repository Name – the name of the repository in Bitbucket Server (e.g. 'conf-dev')

See Integrating Bamboo with Bitbucket Server for more information.

Bitbucket Cloud
This page describes how to configure Bamboo to use a Bitbucket Cloud repository.

If you set up two-factor authentication (2FA) in Bitbucket Cloud, you must configure an app password for Bamboo.

You can specify repositories at the following levels in Bamboo:
- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

On this page:
- Configure a Bitbucket source repository
- Bamboo statuses in Bitbucket Cloud

Note that you will not be able to create plans or jobs that use a Bitbucket repository without first specifying the shared local Mercurial or Git capability. Read more about configuring a Version Control capability.

Related pages:
- Mercurial
- Git

Configure a Bitbucket source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Bitbucket Cloud from the Source Repository list.
4. Enter a Name to help identify the repository in Bamboo.
5. Specify the repository access level and corresponding authentication details for loading the list of repositories:
5.1  Provide the name of the Bitbucket Cloud user who owns the repository in the Owner field. To load the list of repositories available in Bitbucket Cloud you can provide a username and a password or use shared credentials.

5.2  You can configure the following settings of a public or private source repository for your plan:

- **Repository** - retrieves all repositories you have explicit permissions to access from Bitbucket Cloud when you click Load Repositories
- **Branch** - pick a branch if you want to check out code from a branch other than the default branch

5.3  For private repositories, you can specify the authentication method that Bamboo will use to connect to the repository you selected. You can choose from:

- **Username and password** - reuse the credentials provided in step 5.1
- **SSH private key** - provide an SSH key to authenticate; use shared credentials or upload an SSH key and type a passphrase

---

**Advanced Options**

**Command timeout**

This is useful to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Mercurial repository.

**Verbose logs**

For Mercurial: Turns on --verbose and --debug options in Hg or Git commands and passes the output to build logs. Use this option if you encounter problems with Git or Mercurial in Bamboo.

**Enable Quiet Period**

Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

**Include/Exclude Files**

Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

**Exclude Changesets**

Enter a regular expression to match the commit messages for changesets that should not start a build.

**Git LFS**

Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server.

To use this option you must have the following:

- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

---

Bamboo 5.15 is shipped number of images which also include the Git LFS client.

To learn more about Git LFS, see Git LFS tutorials.

**Web Repository**

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

**Note:** This option is not available for Git repositories. See Unable to locate JIRA server for this macro. It may be due to Application Link configuration for more information.

**Mercurial Web Repository** – select one of the following viewer schemes:
• Bitbucket Web Repository Scheme (if you use Bitbucket)
• Default Web Repository Scheme (hgserve) (Mercurial's own default web server)

Stash – specify the following details for the repository:
• Stash URL – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com/').
• Stash Project Key – the key of the project in Stash (e.g. 'CONF').
• Repository Name – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.

Fisheye – specify the following details for the repository:
• Fisheye URL – the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
• Repository Name – the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
• Repository Path – the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

Bamboo statuses in Bitbucket Cloud

You can view the status of Bamboo builds in Bitbucket Cloud.

The feature is set up automatically if you set up a plan in the following way:
• the repository type is Bitbucket Cloud or Bitbucket Server
• you provided Bitbucket credentials (username and password)

The automatic setup of Bamboo build statuses in Bitbucket works with private and public repositories as long as you provide valid Bitbucket credentials.

The build statuses in Bitbucket are displayed in the commit, branch, and pull request views.

For more information about Bamboo statuses in Bitbucket Cloud, see:
• Pull requests and code review
• Integrate your build system with Bitbucket Cloud
• statuses/build Resource

.Bitbucket Cloud v5.14

This page describes how to configure Bamboo to use a Bitbucket Cloud repository.

If you set up two-factor authentication (2FA) in Bitbucket Cloud, you must configure an app password for Bamboo.

You can specify repositories at the following levels in Bamboo:
• global – repositories are available to all plans in Bamboo.
• plan – repositories are available to all jobs in the Bamboo plan.
• job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.
On this page:

- Configure a Bitbucket source repository
- Bamboo statuses in Bitbucket Cloud

Note that you will not be able to create plans or jobs that use a Bitbucket repository without first specifying the shared local Mercurial or Git capability. Read more about configuring a Version Control capability.

Related pages:

- Mercurial
- Git

### Configure a Bitbucket source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Bitbucket Cloud from the Source Repository list.
4. Enter a Name to help identify the repository in Bamboo.
5. Specify the repository access level and corresponding authentication details for loading the list of repositories:

<table>
<thead>
<tr>
<th>Step</th>
<th>Public</th>
<th>Private</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>Provide the name of the Bitbucket Cloud user who owns the repository in the Owner field.</td>
<td>To load the list of repositories available in Bitbucket Cloud you can provide a username and a password or use shared credentials.</td>
</tr>
</tbody>
</table>
| 5.2  | You can configure the following settings of a public or private source repository for your plan:  
- Repository - retrieves all repositories you have explicit permissions to access from Bitbucket Cloud when you click Load Repositories  
- Branch - pick a branch if you want to check out code from a branch other than the default branch | For private repositories, you can specify the authentication method that Bamboo will use to connect to the repository you selected. You can choose from:  
- Username and password - reuse the credentials provided in step 5.1  
- SSH private key - provide an SSH key to authenticate; use shared credentials or upload an SSH key and type a passphrase |
| 5.3  | | Advanced Options |

| Command timeout | This is useful to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Mercurial repository. |
| Verbose logs | For Mercurial: Turns on --verbose and --debug options in Hg or Git commands and passes the output to build logs. Use this option if you encounter problems with Git or Mercurial in Bamboo. |
| Enable Quiet Period | Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build. |
| Include/Exclude Files | Allows you to specify the files that Bamboo should, or should not, use to detect changes. Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples. |
| Exclude Changesets | Enter a regular expression to match the commit messages for changesets that should not start a build. |
### Web Repository

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the ‘Code Changes’ section of a build result.

**Note:** This option is not available for Git repositories. See

> Unable to locate JIRA server for this macro. It may be due to Application Link configuration.

for more information.

**Mercurial Web Repository** – select one of the following viewer schemes:

- Bitbucket Web Repository Scheme (if you use Bitbucket)
- Default Web Repository Scheme (hgserve) (Mercurial’s own default web server)

**Stash** – specify the following details for the repository:

- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. ‘https://bitbucket.mycompany.com’).
- **Stash Project Key** – the key of the project in Stash (e.g. ‘CONF’).
- **Repository Name** – the name of the repository in Stash (e.g. ‘conf-dev’).

Use this option to connect to a Bitbucket Server repository.

See [Integrating Bamboo with Bitbucket Server](#) for more information.

**Fisheye** – specify the following details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. ‘https://atlaseye.atlassian.com’).
- **Repository Name** — the name of your Fisheye repository (e.g. ‘Bamboo’). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. ‘/atlassian/bamboo/’).

See [Integrating Bamboo with Fisheye](#) for more information.

---

### Bamboo statuses in Bitbucket Cloud

You can view the status of Bamboo builds in Bitbucket Cloud.

The feature is set up automatically if you set up a plan in the following way:

**How do I determine my Repository Path?**

If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. `/trunk`). For example, if a code change listed `/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml`, the path would be `/atlassian/bamboo/`. If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.
the repository type is **Bitbucket Cloud** or **Bitbucket Server**

you provided Bitbucket credentials (username and password)

The automatic setup of Bamboo build statuses in Bitbucket works with private and public repositories as long as you provide valid Bitbucket credentials.

The build statuses in Bitbucket are displayed in the commit, branch, and pull request views.

For more information about Bamboo statuses in Bitbucket Cloud, see:

- Pull requests and code review
- Integrate your build system with Bitbucket Cloud
- statuses/build Resource

## Bitbucket Cloud v5.15

This page describes how to configure Bamboo to use a Bitbucket Cloud repository.

If you set up two-factor authentication (2FA) in Bitbucket Cloud, you must configure an app password for Bamboo.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

On this page:

- Configure a Bitbucket source repository
- Bamboo statuses in Bitbucket Cloud

Note that you will not be able to create plans or jobs that use a Bitbucket repository without first specifying the shared local Mercurial or Git capability. Read more about configuring a Version Control capability.

</table>
| **Git LFS**           | Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server. To use this option you must have the following:  
  - Git version 1.8.2 or later installed locally in your environment  
  - Git LFS 1.2 or later installed.  
  Bamboo 5.15 is shipped number of images which also include the Git LFS client.  
  To learn more about Git LFS, see Git LFS tutorials. |
| **Web Repository**    | If your repository can be viewed in a web browser, select the repository type. This allows links to relevant files to be displayed in the 'Code Changes' section of a build result. Note: This option is not available for Git repositories. See Unable to locate JIRA server for this macro. It may be due to Application Link configuration. for more information. |

**Mercurial Web Repository** – select one of the following viewer schemes:  
  - Bitbucket Web Repository Scheme (if you use Bitbucket)  
  - Default Web Repository Scheme (hgserve) (Mercurial's own default web server)
**Stash** — specify the following details for the repository:

- **Stash URL** — the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- **Stash Project Key** — the key of the project in Stash (e.g. 'CONF').
- **Repository Name** — the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See [Integrating Bamboo with Bitbucket Server](#) for more information.

**Fisheye** — specify the following details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
- **Repository Name** — the name of your Fisheye repository (e.g. 'bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See [Integrating Bamboo with Fisheye](#) for more information.

**How do I determine my Repository Path?**

If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed /atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml, the path would be /atlassian/bamboo/.

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

### Bamboo statuses in Bitbucket Cloud

You can view the status of Bamboo builds in Bitbucket Cloud.

The feature is set up automatically if you set up a plan in the following way:

- the repository type is **Bitbucket Cloud** or **Bitbucket Server**
- you provided Bitbucket credentials (username and password)

The automatic setup of Bamboo build statuses in Bitbucket works with private and public repositories as long as you provide valid Bitbucket credentials.

The build statuses in Bitbucket are displayed in the commit, branch, and pull request views.

For more information about Bamboo statuses in Bitbucket Cloud, see:

- [Pull requests and code review](#)
- [Integrate your build system with Bitbucket Cloud](#)
- [statuses/build Resource](#)
This page describes how to configure Bamboo to use a Bitbucket Cloud repository.

If you set up two-factor authentication (2FA) in Bitbucket Cloud, you must configure an app password for Bamboo.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

On this page:

- Configure a Bitbucket source repository
- Bamboo statuses in Bitbucket Cloud

Note that you will not be able to create plans or jobs that use a Bitbucket repository without first specifying the shared local Mercurial or Git capability. Read more about configuring a Version Control capability.

### Configure a Bitbucket source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Bitbucket Cloud from the Source Repository list.
4. Enter a Name to help identify the repository in Bamboo.
5. Specify the repository access level and corresponding authentication details for loading the list of repositories:

<table>
<thead>
<tr>
<th>Step</th>
<th>Public</th>
<th>Private</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>Provide the name of the Bitbucket Cloud user who owns the repository in the Owner field.</td>
<td>To load the list of repositories available in Bitbucket Cloud you can provide a username and a password or use shared credentials.</td>
</tr>
</tbody>
</table>
| 5.2  | You can configure the following settings of a public or private source repository for your plan:  
- Repository - retrieves all repositories you have explicit permissions to access from Bitbucket Cloud when you click Load Repositories  
- Branch - pick a branch if you want to check out code from a branch other than the default branch | For private repositories, you can specify the authentication method that Bamboo will use to connect to the repository you selected. You can choose from:  
- Username and password - reuse the credentials provided in step 5.1  
- SSH private key - provide an SSH key to authenticate; use shared credentials or upload an SSH key and type a passphrase |

### Advanced Options

**Command timeout**

This is useful to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Mercurial repository.

**Verbose logs**

For Mercurial: Turns on --verbose and --debug options in Hg or Git commands and passes the output to build logs. Use this option if you...
encounter problems with Git or Mercurial in Bamboo.

Enable Quiet Period
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

Exclude Changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Git LFS
Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server.

To use this option you must have the following:
- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

Bamboo 5.15 is shipped number of images which also include the Git LFS client.

To learn more about Git LFS, see Git LFS tutorials.

Web Repository
If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

Note: This option is not available for Git repositories. See

Unable to locate JIRA server for this macro. It may be due to Application Link configuration. for more information.

Mercurial Web Repository – select one of the following viewer schemes:

- Bitbucket Web Repository Scheme (if you use Bitbucket)
- Default Web Repository Scheme (hgserve) (Mercurial's own default web server)

Mercurial Web Repository Scheme

- Stash URL – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- Stash Project Key – the key of the project in Stash (e.g. 'CONF').
- Repository Name – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.

Fisheye – specify the following details for the repository:

- Fisheye URL — the URL of your Fisheye repository (e.g. 'https://atlas-eye.atlassian.com/').
- Repository Name — the name of your Fisheye repository (e.g. 'bamboo'). This is effectively the alias for your repository path.
- Repository Path — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

How do I determine my Repository Path?
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed /atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml, the path would be /atlassian/bamboo/.

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.
**Bamboo statuses in Bitbucket Cloud**

You can view the status of Bamboo builds in Bitbucket Cloud.

The feature is set up automatically if you set up a plan in the following way:

- the repository type is Bitbucket Cloud or Bitbucket Server
- you provided Bitbucket credentials (username and password)

The automatic setup of Bamboo build statuses in Bitbucket works with private and public repositories as long as you provide valid Bitbucket credentials.

The build statuses in Bitbucket are displayed in the commit, branch, and pull request views.

For more information about Bamboo statuses in Bitbucket Cloud, see:

- Pull requests and code review
- Integrate your build system with Bitbucket Cloud
- statuses/build Resource

**Stash**

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

When you link a repository hosted in Atlassian's Stash (now Bitbucket Server) with a build plan in Bamboo, then without any further configuration:

- Bamboo will automatically run a build when changes are pushed to the Stash repository, without needing to configure polling.
- Bamboo will automatically update plan branches when a developer pushes a new branch to the repository (or deletes a branch).
- You can click through to Stash to see the commit diff for all files that are part of the changeset.
- Stash commits that are part of a build are displayed in Bamboo.
- Build results are notified to Stash (and displayed for the associated commits and pull requests).

On this page:

- Configuration requirements

Stash and Bamboo only need to have been connected by creating an application link. Repositories in Stash are then made available in Bamboo, so it's easy for you to link your Bamboo plan to a Stash repository.

When you create a plan that uses a Stash source repository, with Stash 3.1 and later, Bamboo will automatically use the 'Stash repository triggers the build when changes are committed' trigger option instead of using the 'polling the repository for changes' option. This reduces the load on the Bamboo and Stash servers because Bamboo doesn't need to send poll requests (for each branch of each plan) to the Stash server every 3 minutes (the default polling period). Instead, Stash will trigger Bamboo whenever there is a push to the repository.

**Configuration requirements**

Navigate to the source repository settings for a plan or job, as described on Linking to source code repositories, then:

1. Either click Add Repository to add a new repository, or edit an existing repository configuration.
2. Choose Stash from the Repository host list.
3. Complete the required information:

   **Display name**
   A name that identifies this repository within Bamboo.

   **Stash server**
   This menu will show all Stash servers that have been linked to Bamboo via an application link.

   **Repository**
   The repository that will be built. This menu will show all repositories on the Stash server that you have permissions to access.
Branch
Pick a branch if you want to check out code from a branch other than the default branch.

Advanced Options

Use shallow clones
Allows Bamboo to perform shallow clones (i.e. history truncated to a specified number of revisions). This should increase the speed of the initial code checkout, however if your build depends on the full repository history, we recommend that you do not use this option. Shallow clones are enabled by default.

Enable repository caching on remote agents
Allow caching of repositories on remote agents to save bandwidth. Note that caches are always full clones of the source repository.

Use submodules
Select to enable submodules support if these are defined for the repository. If native Git capability is not defined for agent submodules support will be disabled.

Command timeout
This helps to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Git repository.

Verbose logs
Turns on more verbose logs from Git commands. Use this option if you encounter problems with Git in Bamboo.

Fetch whole repository
Fetches whole repository instead of only one selected branch.

Enable Quiet Period
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use only the mentioned files for change detection (by default Bamboo checks all the files). In the same way, if you configure the Exclude option, Bamboo will not consider the excluded files when detecting changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See this page for examples.

Exclude changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Git LFS
Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server.
To use this option you must have the following:
- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

Bamboo 5.15 is shipped number of images which also include the Git LFS client.

To learn more about Git LFS, see Git LFS tutorials.

Web repository
If your repository can be viewed in a web browser, select the repository type.
This allows links to relevant files to be displayed in the ‘Code Changes’ section of a build result.

Stash – specify the following details for the repository:
- Stash URL – the URL of your Stash instance (e.g. https://stash.mycompany.com).
- Stash Project Key – the key of the project in Stash (e.g. 'CONF').
- Repository Name – the name of the repository in Stash (e.g. 'conf-dev').

See Integrating Bamboo with Bitbucket Server for more information.

.Stash v5.14
You can specify repositories at the following levels in Bamboo:
- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.
When you link a repository hosted in Atlassian's Stash (now Bitbucket Server) with a build plan in Bamboo, then without any further configuration:

- Bamboo will automatically run a build when changes are pushed to the Stash repository, without needing to configure polling.
- Bamboo will automatically update plan branches when a developer pushes a new branch to the repository (or deletes a branch).
- You can click through to Stash to see the commit diff for all files that are part of the changeset.
- Stash commits that are part of a build are displayed in Bamboo.
- Build results are notified to Stash (and displayed for the associated commits and pull requests).

Stash and Bamboo only need to have been connected by creating an application link. Repositories in Stash are then made available in Bamboo, so it is easy for you to link your Bamboo plan to a Stash repository.

When you create a plan that uses a Stash source repository, with Stash 3.1 and later, Bamboo will automatically use the "Stash repository triggers the build when changes are committed" trigger option instead of using the 'polling the repository for changes' option. This reduces the load on the Bamboo and Stash servers because Bamboo doesn't need to send poll requests (for each branch of each plan) to the Stash server every 3 minutes (the default polling period). Instead, Stash will trigger Bamboo whenever there is a push to the repository.

**Configuration requirements**

Navigate to the source repository settings for a plan or job, as described on Linking to source code repositories, then:

1. Either click Add Repository to add a new repository, or edit an existing repository configuration.
2. Choose Stash from the Repository host list.
3. Complete the required information:

<table>
<thead>
<tr>
<th>Display name</th>
<th>A name that identifies this repository within Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stash server</td>
<td>This menu will show all Stash servers that have been linked to Bamboo via an application link.</td>
</tr>
<tr>
<td>Repository</td>
<td>The repository that will be built. This menu will show all repositories on the Stash server that you have permissions to access.</td>
</tr>
<tr>
<td>Branch</td>
<td>Pick a branch if you want to check out code from a branch other than the default branch.</td>
</tr>
</tbody>
</table>

**Advanced options**

- Use shallow clones: Allows Bamboo to perform shallow clones (i.e. history truncated to a specified number of revisions). This should increase the speed of the initial code checkouts, however if your build depends on the full repository history, we recommend that you do not use this option. Shallow clones are enabled by default.
- Enable repository caching on remote agents: Allow caching of repositories on remote agents to save bandwidth. Note that caches are always full clones of the source repository.
- Use submodules: Select to enable submodules support if these are defined for the repository. If native Git capability is not defined for agent submodules support will be disabled.
- Command timeout: This helps to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Git repository.
- Verbose logs: Turns on more verbose logs from Git commands. Use this option if you encounter problems with Git in Bamboo.
- Fetch whole repository: Fetches whole repository instead of only one selected branch.
- Enable Quiet Period: Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.
Include/Exclude Files

Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use only the mentioned files for change detection (by default Bamboo checks all the files). In the same way, if you configure the Exclude option, Bamboo will not consider the excluded files when detecting changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See this page for examples.

Exclude changesets

Enter a regular expression to match the commit messages for changesets that should not start a build.

Web repository

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

Stash – specify the following details for the repository:

- **Stash URL** – the URL of your Stash instance (e.g. https://stash.mycompany.com).
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

See Integrating Bamboo with Bitbucket Server for more information.

Stash v5.15

You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

When you link a repository hosted in Atlassian's Stash (now Bitbucket Server) with a build plan in Bamboo, then without any further configuration:

- Bamboo will automatically run a build when changes are pushed to the Stash repository, without needing to configure polling.
- Bamboo will automatically update plan branches when a developer pushes a new branch to the repository (or deletes a branch).
- You can click through to Stash to see the commit diff for all files that are part of the changeset.
- Stash commits that are part of a build are displayed in Bamboo.
- Build results are notified to Stash (and displayed for the associated commits and pull requests).

On this page:
- Configuration requirements

Stash and Bamboo only need to have been connected by creating an application link. Repositories in Stash are then made available in Bamboo, so it is easy for you to link your Bamboo plan to a Stash repository.

When you create a plan that uses a Stash source repository, with Stash 3.1 and later, Bamboo will automatically use the 'Stash repository triggers the build when changes are committed' trigger option instead of using the 'polling the repository for changes' option. | Git LFS                                      | Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server. To use this option you must have the following:  
  - Git version 1.8.2 or later installed locally in your environment  
  - Git LFS 1.2 or later installed.  

Bamboo 5.15 is shipped number of images which also include the Git LFS client.

To learn more about Git LFS, see Git LFS tutorials.
### Web repository

If your repository can be viewed in a web browser, select the repository type. This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

**Stash** – specify the following details for the repository:
- **Stash URL** – the URL of your Stash instance (e.g. 'https://stash.mycompany.com').
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

See [Integrating Bamboo with Bitbucket Server](https://www.atlassian.com/git/tutorials/handle-source-code-changes-with-bitbucket-server) for more information.

---

### .Stash v6.1

You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](https://www.atlassian.com/git/tutorials/handle-source-code-changes-with-bitbucket-server).

When you link a repository hosted in Atlassian's Stash (now Bitbucket Server) with a build plan in Bamboo, then without any further configuration:

- Bamboo will automatically run a build when changes are pushed to the Stash repository, without needing to configure polling.
- Bamboo will automatically update plan branches when a developer pushes a new branch to the repository (or deletes a branch).
- You can click through to Stash to see the commit diff for all files that are part of the changeset.
- Stash commits that are part of a build are displayed in Bamboo.
- Build results are notified to Stash (and displayed for the associated commits and pull requests).

### On this page:
- **Configuration requirements**

Stash and Bamboo only need to have been connected by [creating an application link](https://confluence.atlassian.com/pmlisv/creating-an-application-link-826897053.html). Repositories in Stash are then made available in Bamboo, so it is easy for you to link your Bamboo plan to a Stash repository.

When you create a plan that uses a Stash source repository, with Stash 3.1 and later, Bamboo will automatically use the 'Stash repository triggers the build when changes are committed' trigger option instead of using the 'polling the repository for changes' option. This reduces the load on the Bamboo and Stash servers because Bamboo doesn't need to send poll requests (for each branch of each plan) to the Stash server every 3 minutes (the default polling period). Instead, Stash will trigger Bamboo whenever there is a push to the repository.

### Configuration requirements

Navigate to the source repository settings for a plan or job, as described on [Linking to source code repositories](https://confluence.atlassian.com/pmlisv/creating-an-application-link-826897053.html), then:

1. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
2. Choose **Stash** from the **Repository host** list.
3. Complete the required information:

   **Display name**
   A name that identifies this repository within Bamboo.

   **Stash server**
   This menu will show all Stash servers that have been linked to Bamboo via an application link.

   **Repository**
   The repository that will be built. This menu will show all repositories on the Stash server that you have permissions to access.

   **Branch**
   Pick a branch if you want to check out code from a branch other than the default branch.

### Advanced Options

**Use shallow clones**
Allows Bamboo to perform shallow clones (i.e. history truncated to a specified number of revisions). This should increase the speed of the initial code checkouts, however if your build depends on the full repository history, we recommend that you do not use this option. Shallow clones are enabled by default.

**Enable repository caching on remote agents**
Allow caching of repositories on remote agents to save bandwidth. Note that caches are always full clones of the source repository.

**Use submodules**
Select to enable submodules support if these are defined for the repository. If native Git capability is not defined for agent submodules support will be disabled.

**Command timeout**
This helps to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Git repository.

**Verbose logs**
Turns on more verbose logs from Git commands. Use this option if you encounter problems with Git in Bamboo.

**Fetch whole repository**
Fetches whole repository instead of only one selected branch.

**Enable Quiet Period**
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

**Include/Exclude Files**
Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use only the mentioned files for change detection (by default Bamboo checks all the files). In the same way, if you configure the Exclude option, Bamboo will not consider the excluded files when detecting changes.

Enter into **File Pattern** a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See this page for examples.

**Exclude changesets**
Enter a regular expression to match the commit messages for changesets that should not start a build.

**Git LFS**
Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server.
To use this option you must have the following:
- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

Bamboo 5.15 is shipped number of images which also include the Git LFS client.

To learn more about Git LFS, see Git LFS tutorials.

**Web repository**
If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

**Stash** – specify the following details for the repository:
- **Stash URL** – the URL of your Stash instance (e.g. 'https://stash.mycompany.com').
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

See Integrating Bamboo with Bitbucket Server for more information.

**Git**
This page describes how to configure Bamboo to use a Git repository.

You can specify repositories at the following levels in Bamboo:
- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

You need to have previously defined a Git capability before you can configure a Git source repository – see Defining a new version control capability.

Note that Bamboo comes with its own built-in Git implementation. However, you need to use native Git to be able to use symbolic links,
submodules, automatic branch detection and automatic merging - these are not supported by the built-in Git.

You can download Git from the following locations:

- For Windows
- For Linux and Mac

Related pages:
- Bitbucket Cloud
- GitHub
- Defining a new version control capability

Configure a Git source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Git from the Source Repository list.
4. Enter a Name to help identify the repository in Bamboo.
5. You can configure the following settings for a Git source repository for your plan:

Repository URL

The full path to your Git repository (eg: https://bitbucket.org/atlassian/bamboo-git-plugin.git)

Valid URLs are of the form:

- `git://host.xz[:port]/path/to/repo.git`
- `ssh://[user@]host.xz[:port]/path/to/repo.git`
- `[user@]host.xz[:port]/path/to/repo.git`
- `http[s]://host.xz[:port]/path/to/repo.git`
- `/path/to/repo.git`
- `file:///path/to/repo.git`

Branch

Type the name of the relevant branch (or tag) you want to work on. Leave empty to work on the master branch.

Authentication Type

- None – choose if you want to access the repository anonymously
- Username and password – use shared credentials or type a username and a password
- SSH private key – use shared credentials or upload an SSH key and provide the SSH passphrase

Use shallow clones

Allows Bamboo to perform shallow clones (i.e. history truncated to a specified number of revisions). This should increase the speed of the initial code checkouts, however if your build depends on the full repository history, we recommend that you do not use this option. Shallow clones are enabled by default.

Location of POM file

The path to your project's `pom.xml` file, relative to the root of your Git Repository URL (defined above).

(Only available when importing a Maven 2 project)

Git LFS

Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server.

To use this option you must have the following:

- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

Bamboo 5.15 is shipped with different images which also include the Git LFS client.

Advanced Options

Use submodules

Select to enable submodules support if these are defined for the repository. If native Git capability is not defined for agent submodules support will be disabled.
Command timeout
This is useful to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Git repository.

Verbose logs
Turns on more verbose logs from Git commands. Use this option if you encounter problems with Git in Bamboo.

Enable Quiet Period
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use only the mentioned files for change detection because by default Bamboo checks all the files. The same way, if you configure the Exclude option, Bamboo will not consider the excluded files for detecting changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

Exclude Changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Git LFS
Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server.

To use this option you must have the following:
- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

To learn more about Git LFS, see Git LFS tutorials.

Web repository
If your repository can be viewed in a web browser, select the repository type.
This allows links to relevant files to be displayed in the Code Changes section of a build result.

Stash — specify the following details for the repository:
- Stash URL — the URL of your Stash (now Bitbucket Server) instance (e.g. https://bitbucket.mycompany.com).
- Stash Project Key — the key of the project in Stash (e.g. 'CONF').
- Repository Name — the name of the repository in Stash (e.g. 'conf-dev').

See Integrating Bamboo with Bitbucket Server for more information.

Fisheye — specify the URL and other details for the repository:
- Fisheye URL — the URL of your Fisheye repository (e.g. https://atlaseye.atlassian.com/).
- Repository Name — the name of your Fisheye repository (e.g. 'bamboo'). This is effectively the alias for your repository path.
- Repository Path — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

How do I determine my Repository Path?
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed /atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml, the path would be /atlassian/bamboo/.
If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

Configuring Git SSH on Windows

Bamboo 5.15 is shipped with Git LFS client image.

To learn more about Git LFS, see Git LFS tutorials.
SSH overview

You can use SSH keys to establish a secure connection between the Bamboo server and the SCM that hosts Git repositories.

- If no Git capability is configured, Bamboo will use its built-in Git implementation: the built-in Git implementation does not support symbolic links, submodules, automatic branch detection and automatic merging.
- Your SCM administrator must have already enabled SSH access to Git repositories.
- Supported key types are DSA and RSA2. Note that RSA1 is not supported. We've tested key sizes of 768, 1024, 2048, 4096 and 8192 bytes.

Enabling SSH access to Git repositories

To enable SSH access:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Linked repositories (under 'Build resources')
3. Click Add repository, and select Git from the Source repository menu
4. Complete the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display name</td>
<td>The name that identifies the repository when you are using multiple repositories in a plan</td>
</tr>
<tr>
<td>Repository URL</td>
<td>The URL of the Git repository</td>
</tr>
<tr>
<td>Branch</td>
<td>The name of the branch or tag containing the source code</td>
</tr>
</tbody>
</table>

5. Select SSH private key from the Authentication Key menu
6. Select the file containing your SSH key using the 'Choose File' button
7. Enter the passphrase to allow access to your SSH key
8. Click Save repository

Once you have enabled SSH access, you will also need to add an SSH server capability:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Server capabilities and scroll to the bottom of the page
3. Click Add under the 'Add capability' heading
4. Complete the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Capability type</td>
<td>Git</td>
</tr>
<tr>
<td>Executable</td>
<td>SSH</td>
</tr>
<tr>
<td>Path</td>
<td>The path to the SSH executable, for example: /usr/bin/ssh</td>
</tr>
</tbody>
</table>

5. Click Add to add the SSH capability.

Configuring Git SSH on Windows v5.14

SSH overview

You can use SSH keys to establish a secure connection between the Bamboo server and the SCM that hosts Git repositories.

- If no Git capability is configured, Bamboo will use its built-in Git implementation: the built-in Git implementation does not support symbolic links, submodules, automatic branch detection and automatic merging.
- Your SCM administrator must have already enabled SSH access to Git repositories.
1. Supported key types are DSA and RSA. Note that RSA1 is not supported. We've tested key sizes of 768, 1024, 2048, 4096 and 8192 bytes.

Git repository connectivity using SSH under Windows

The Bamboo Developers recommend that you use Cygwin SSH client instead of the SSH client bundled with Git. Cygwin SSH offers significantly improved speed, stability and configuration options over the one bundled with Git.

1. Download the relevant Cygwin packages from cygwin.com
2. Run the executable, selecting the default options until you reach the 'Select package' menu
3. Select the following packages from the menu:
   - git-completion
   - git-gui
   - git-k
   - openssh

Next you need to configure the Cygwin SSH instance.

1. Open the C:\cygwin directory and edit the Cydgwin.bat file in a text editor. Add this line:
   ```bash
   set CYGWIN=binmode ntsec
   ```
   before the line that invokes the bash shell
2. Next we will check that Cygwin was correctly installed. Run C:\Cygwin\Cygwin.bat, and run the following command:
   ```bash
   cygrunsrv -h
   ```

This should display a listing of Cygwin help commands. If not, then something has gone wrong and you will need to reinstall Cygwin.

Once you have configured your SSH service, follow the steps described below for enabling access to Git repositories. You will also need to add an SSH capability for each local and remote agent.

Enabling SSH access to Git repositories

To enable SSH access:

You need to set up SSH access when you configure your linked repositories:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Linked repositories (under 'Build resources')
3. Click Add repository, and select Git from the Source repository menu
4. Complete the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display name</td>
<td>The name that identifies the repository when you are using multiple repositories in a plan</td>
</tr>
<tr>
<td>Repository URL</td>
<td>The URL of the Git repository</td>
</tr>
<tr>
<td>Branch</td>
<td>The name of the branch or tag containing the source code</td>
</tr>
</tbody>
</table>

5. Select SSH private key from the Authentication Key menu
6. Select the file containing your SSH key using the 'Choose File' button
7. Enter the passphrase to allow access to your SSH key
8. Click Save repository

Once you have enabled SSH access, you will also need to add an SSH server capability:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Server capabilities and scroll to the bottom of the page
3. Click Add under the 'Add capability' heading
4. Complete the following fields:
Enabling SSH access to Git repositories

To enable SSH access:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Linked repositories (under 'Build resources')
3. Click Add repository, and select Git from the Source repository menu
4. Complete the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display name</td>
<td>The name that identifies the repository when you are using multiple repositories in a plan</td>
</tr>
<tr>
<td>Repository URL</td>
<td>The URL of the Git repository</td>

<td>Git</td>
</tr>
<tr>
<td>Executable</td>
<td>SSH</td>
</tr>
<tr>
<td>Path</td>
<td>The path to the SSH executable, for example: /usr/bin/ssh</td>
</tr>
</tbody>
</table>
5. Click **Add** to add the SSH capability.

---

### Git LFS for Bamboo

**.Git LFS v5.15**

Starting from version 5.15, Bamboo provides native support for Git Large File Storage (LFS) for hosted repositories.

**Requirements**

To use Bamboo's support your environment must meet the following requirements:

- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later.

Bamboo 5.15 is shipped with Git LFS client image.

**.Git v5.15**

This page describes how to configure Bamboo to use a Git repository.

You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see **Linking to source code repositories**.

You need to have previously defined a Git capability before you can configure a Git source repository – see **Defining a new version control capability**.

Note that Bamboo comes with its own built-in Git implementation. However, you need to use native Git to be able to use symbolic links, submodules, automatic branch detection and automatic merging - these are not supported by the built-in Git.

You can download Git from the following locations:

- **For Windows**
- **For Linux and Mac**

**Related pages:**

- Bitbucket Cloud
- GitHub
- Defining a new version control capability

---

### Configure a Git source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See **Linking to source code repositories**.
2. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
3. Choose **Git** from the **Source Repository** list.
4. Enter a **Name** to help identify the repository in Bamboo.
5. You can configure the following settings for a Git source repository for your plan:

<table>
<thead>
<tr>
<th><strong>Repository URL</strong></th>
<th>The full path to your Git repository (eg: <a href="https://bitbucket.org/atlassian/bamboo-git-plugin.git">https://bitbucket.org/atlassian/bamboo-git-plugin.git</a>)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid URLs are of the form:</td>
<td></td>
</tr>
</tbody>
</table>
  - git://host.xz[:port]/path/to/repo.git
  - ssh://[user@]host.xz[:port]/path/to/repo.git
  - [user@]host.xz[:port]/path/to/repo.git
  - http[s]://host.xz[:port]/path/to/repo.git
  - /path/to/repo.git
  - file:///path/to/repo.git |

<p>| <strong>Branch</strong> | Type the name of the relevant branch (or tag) you want to work on. Leave empty to work on the <strong>master</strong> branch. |
| <strong>Authentication Type</strong> | <strong>None</strong> – choose if you want to access the repository anonymously |
| | <strong>Username and password</strong> – use <strong>shared credentials</strong> or type a username and a password |</p>
<table>
<thead>
<tr>
<th>SSH private key</th>
<th>— use shared credentials or upload an SSH key and provide the SSH passphrase</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use shallow clones</strong></td>
<td>Allows Bamboo to perform shallow clones (i.e. history truncated to a specified number of revisions). This should increase the speed of the initial code checkouts, however if your build depends on the full repository history, we recommend that you do not use this option. Shallow clones are enabled by default.</td>
</tr>
<tr>
<td><strong>Location of POM file</strong></td>
<td>The path to your project’s <code>pom.xml</code> file, relative to the root of your Git Repository URL (defined above). (Only available when importing a Maven 2 project)</td>
</tr>
</tbody>
</table>

| **Git LFS** | Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server. To use this option you must have the following:  
  * Git version 1.8.2 or later installed locally in your environment  
  * Git LFS 1.2 or later installed. |

**Advanced Options**

<table>
<thead>
<tr>
<th><strong>Use submodules</strong></th>
<th>Select to enable submodules support if these are defined for the repository. If native Git capability is not defined for agent submodules support will be disabled.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command timeout</strong></td>
<td>This is useful to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Git repository.</td>
</tr>
<tr>
<td><strong>Verbose logs</strong></td>
<td>Turns on more verbose logs from Git commands. Use this option if you encounter problems with Git in Bamboo.</td>
</tr>
<tr>
<td><strong>Enable Quiet Period</strong></td>
<td>Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.</td>
</tr>
<tr>
<td><strong>Include/Exclude Files</strong></td>
<td>Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use only the mentioned files for change detection because by default Bamboo checks all the files. The same way, if you configure the Exclude option, Bamboo will not consider the excluded files for detecting changes. Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.</td>
</tr>
<tr>
<td><strong>Exclude Changesets</strong></td>
<td>Enter a regular expression to match the commit messages for changesets that should not start a build.</td>
</tr>
</tbody>
</table>
| **Git LFS** | Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server. To use this option you must have the following:  
  * Git version 1.8.2 or later installed locally in your environment  
  * Git LFS 1.2 or later installed. |

**Web repository**

Bamboo 5.15 is shipped with different images which also include the Git LFS client.

To learn more about Git LFS, see [Git LFS tutorials](#).
### Web Repository

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

**Stash** – specify the following details for the repository:

- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. `https://bitbucket.mycompany.com`).
- **Stash Project Key** – the key of the project in Stash (e.g. `CONF`).
- **Repository Name** – the name of the repository in Stash (e.g. `conf-dev`).

Use this option to connect to a Bitbucket Server repository.

See [Integrating Bamboo with Bitbucket Server](#) for more information.

**Fisheye** – specify the URL and other details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. `https://atlaseye.atlassian.com/`).
- **Repository Name** — the name of your Fisheye repository (e.g. `Bamboo`). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. `atlassian/bamboo/`).

See [Integrating Bamboo with Fisheye](#) for more information.

---

**.Git v5.14**

This page describes how to configure Bamboo to use a Git repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

You need to have previously defined a Git capability before you can configure a Git source repository – see [Defining a new version control capability](#).

**Note** that Bamboo comes with its own built-in Git implementation. However, you need to use native Git to be able to use symbolic links, submodules, automatic branch detection and automatic merging - these are not supported by the built-in Git.

You can download Git from the following locations:

- **Windows**: [http://code.google.com/p/msysgit/downloads/list?can=3&q=official+Git](http://code.google.com/p/msysgit/downloads/list?can=3&q=official+Git)
- **Linux and Mac**: [http://git-scm.com/download](http://git-scm.com/download)
Configure a Git source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Git from the Source Repository list.
4. Enter a Name to help identify the repository in Bamboo.
5. You can configure the following settings for a Git source repository for your plan:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository URL</strong></td>
<td>The full path to your Git repository (eg: <a href="https://bitbucket.org/atlassian/bamboo-git-plugin.git">https://bitbucket.org/atlassian/bamboo-git-plugin.git</a>)</td>
</tr>
<tr>
<td></td>
<td>Valid URLs are of the form:</td>
</tr>
<tr>
<td></td>

### Include/Exclude Files

Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use only the mentioned files for change detection because by default Bamboo checks all the files. The same way, if you configure the Exclude option, Bamboo will not consider the excluded files for detecting changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

### Exclude Changesets

Enter a regular expression to match the commit messages for changesets that should not start a build.

### Web Repository

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

#### Stash

- **Stash URL** — the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- **Stash Project Key** — the key of the project in Stash (e.g. 'CONF').
- **Repository Name** — the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.

#### Fisheye

- **Fisheye URL** — the URL of your Fisheye repository (e.g. https://atlaseye.atlassian.com/).
- **Repository Name** — the name of your Fisheye repository (e.g. 'bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

---

**How do I determine my Repository Path?**

If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed /atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml, the path would be /atlassian/bamboo/. If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.
You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

You need to have previously defined a Git capability before you can configure a Git source repository – see [Defining a new version control capability](#).

Note that Bamboo comes with its own built-in Git implementation. However, you need to use native Git to be able to use symbolic links, submodules, automatic branch detection and automatic merging - these are not supported by the built-in Git.

You can download Git from the following locations:

- For Windows
- For Linux and Mac

**Related pages:**
- Bitbucket Cloud
- GitHub
- Defining a new version control capability

---

**Configure a Git source repository**

1. Navigate to the repository configuration for a linked repository, plan or job. See [Linking to source code repositories](#).
2. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
3. Choose **Git** from the **Source Repository** list.
4. Enter a **Name** to help identify the repository in Bamboo.
5. You can configure the following settings for a Git source repository for your plan:

**Repository URL**

The full path to your Git repository (e.g: `https://bitbucket.org/atlassian/bamboo-git-plugin.git`)

Valid URLs are of the form:

- `git://host.xz[:port]/path/to/repo.git`
- `ssh://[user@]host.xz[:port]/path/to/repo.git`
- `[user@]host.xz[:port]/path/to/repo.git`
- `http[s]://host.xz[:port]/path/to/repo.git`
- `/path/to/repo.git`
- `file:///path/to/repo.git`

**Branch**

Type the name of the relevant branch (or tag) you want to work on. Leave empty to work on the `master` branch.

**Authentication Type**

- **None** – choose if you want to access the repository anonymously
- **Username and password** – use shared credentials or type a username and a password
- **SSH private key** – use shared credentials or upload an SSH key and provide the SSH passphrase

**Use shallow clones**

Allows Bamboo to perform shallow clones (i.e. history truncated to a specified number of revisions). This should increase the speed of the initial code checkouts, however if your build depends on the full repository history, we recommend that you do not use this option. Shallow clones are enabled by default.

**Location of POM file**

The path to your project's `pom.xml` file, relative to the root of your Git Repository URL (defined above).

*(Only available when importing a Maven 2 project)*

**Git LFS**

Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server.

To use this option you must have the following:

- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

Bamboo 5.15 is shipped with different images which also include the Git LFS client.
Advanced Options

Use submodules
Select to enable submodules support if these are defined for the repository. If native Git capability is not defined for agent submodules support will be disabled.

Command timeout
This is useful to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Git repository.

Verbose logs
Turns on more verbose logs from Git commands. Use this option if you encounter problems with Git in Bamboo.

Enable Quiet Period
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use only the mentioned files for change detection because by default Bamboo checks all the files. The same way, if you configure the Exclude option, Bamboo will not consider the excluded files for detecting changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

Exclude Changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Git LFS
Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server.

To use this option you must have the following:
- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

To learn more about Git LFS, see Git LFS tutorials.

Web repository

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

Stash – specify the following details for the repository:

- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. `https://bitbucket.mycompany.com`).
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

See Integrating Bamboo with Bitbucket Server for more information.

Fisheye – specify the URL and other details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. `https://atlaseye.atlassian.com/`).
- **Repository Name** — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

How do I determine my Repository Path?

If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk)). For example, if a code change listed `/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml`, the path would be `atlassian/bamboo/trunk/bamboo-acceptance-test`. If you are using Git LFS, the path would be `atlassian/bamboo/trunk/bamboo-acceptance-test-pom.xml`. If you are using submodules, you should use the submodule path at the top of the submodule repository (e.g. `atlassian/bamboo`).
.Git v6.4
This page describes how to configure Bamboo to use a Git repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

You need to have previously defined a Git capability before you can configure a Git source repository – see Defining a new version control capability.

Note that Bamboo comes with its own built-in Git implementation. However, you need to use native Git to be able to use symbolic links, submodules, automatic branch detection and automatic merging - these are not supported by the built-in Git.

You can download Git from the following locations:

- For Windows
- For Linux and Mac

**Related pages:**
- Bitbucket Cloud
- GitHub
- Defining a new version control capability

**Configure a Git source repository**

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
3. Choose **Git** from the **Source Repository** list.
4. Enter a **Name** to help identify the repository in Bamboo.
5. You can configure the following settings for a Git source repository for your plan:

**Repository URL**

The full path to your Git repository (eg: `https://bitbucket.org/atlassian/bamboo-git-plugin.git`)

Valid URLs are of the form:

- `git://host.xz[:port]/path/to/repo.git`
- `ssh://[user@]host.xz[:port]/path/to/repo.git`
- `[user@]host.xz[:port]/path/to/repo.git`
- `http[s]://host.xz[:port]/path/to/repo.git`
- `/path/to/repo.git`
- `file:///path/to/repo.git`

**Branch**

Type the name of the relevant branch (or tag) you want to work on. Leave empty to work on the **master** branch.

**Authentication Type**

- **None** – choose if you want to access the repository anonymously
- **Username and password** – use shared credentials or type a username and a password
- **SSH private key** – use shared credentials or upload an SSH key and provide the SSH passphrase

**Use shallow clones**

Allows Bamboo to perform shallow clones (i.e. history truncated to a specified number of revisions). This should increase the speed of the initial code checkouts, however if your build depends on the full repository history, we recommend that you do not use this option. Shallow clones are enabled by default.

**Location of POM file**

The path to your project's **pom.xml** file, relative to the root of your Git **Repository URL** (defined above).
(Only available when importing a Maven 2 project)

**Git LFS**
Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server.
To use this option you must have the following:
- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

Bamboo 5.15 is shipped with different images which also include the Git LFS client.

Advanced Options

**Use submodules**
Select to enable submodules support if these are defined for the repository. If native Git capability is not defined for agent submodules support will be disabled.

**Command timeout**
This is useful to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the Git repository.

**Verbose logs**
Turns on more verbose logs from Git commands. Use this option if you encounter problems with Git in Bamboo.

**Enable Quiet Period**
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

**Include/Exclude Files**
Allows you to specify the files that Bamboo should, or should not, use to detect changes. When you configure the Include option, it means that you want Bamboo to use only the mentioned files for change detection because by default Bamboo checks all the files. The same way, if you configure the Exclude option, Bamboo will not consider the excluded files for detecting changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

**Exclude Changesets**
Enter a regular expression to match the commit messages for changesets that should not start a build.

**Git LFS**
Enables support for Git Large File Storage (LFS), which replaces large files such as audio samples, videos, datasets, and graphics with text pointers inside Git, while storing the file contents on a remote server.
To use this option you must have the following:
- Git version 1.8.2 or later installed locally in your environment
- Git LFS 1.2 or later installed.

Bamboo 5.15 is shipped with Git LFS client image.

To learn more about Git LFS, see Git LFS tutorials.

**Web repository**
If your repository can be viewed in a web browser, select the repository type.
This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

**Stash** – specify the following details for the repository:
- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.

**Fisheye** – specify the URL and other details for the repository:
- **Fisheye URL** — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
- **Repository Name** — the name of your Fisheye repository (e.g. 'bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See [Integrating Bamboo with Fisheye](#) for more information.

---

**How do I determine my Repository Path?**

If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed `/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml`, the path would be `/atlassian/bamboo/`.

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

---

**Hiding password for https Git tasks**

Starting from Bamboo 6.4, you Git username and password will be stored in a URL kept in turn in a temporary file which will be deleted. This way only Bamboo will have access to your Git credentials preventing other users on the same machine from viewing your data.

If you're using Git Credential Manager for Windows, Gut might ask you for your credentials not at the bash but in the Credential Manager. Because it's operating on your server or agent, you won't be able to see the see the Credential Manager display.

For more information about storing credentials in Git, see [Git Tools Credential Storage](#).

---

**GitHub**

This page describes how to configure Bamboo to use a GitHub repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

**Configure a GitHub source code repository**

1. Navigate to the repository configuration for a linked repository, plan or job. See [Linking to source code repositories](#).
2. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
3. Choose **GitHub** from the **Source repository** list.
4. Enter a **Display Name** to help identify the repository in Bamboo.
5. Enter your GitHub **Username** and **Password**.
6. **Click Load Repositories**.
7. You can configure the following advanced options for a GitHub source repository for your plan:

**Advanced Options**

**Use submodules**

Select to enable submodules support if these are defined for the repository. If native GitHub capability is not defined for agent submodules support will be disabled.

**Command timeout**

This is useful to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the GitHub repository.

**Verbose logs**

Turns on `--verbose` and `--debug` options in hg commands and passes the output to build logs. Use this option if you encounter problems with GitHub in Bamboo.

**Enable Quiet Period**

Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

**Include/Exclude Files**

Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into **File Pattern** a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See [sub page](#) for examples.
Exclude Changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Web Repository

Stash – specify the following details for the repository:
- Stash URL – the URL of your Stash (now Bitbucket Server) instance (e.g. `https://bitbucket.mycompany.com`).
- Stash Project Key – the key of the project in Stash (e.g. 'CONF').
- Repository Name – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.

Fisheye – specify the URL and other details for the repository:
- Fisheye URL — the URL of your Fisheye repository (e.g. `https://atlaseye.atlassian.com`).
- Repository Name — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- Repository Path — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

How do I determine my Repository Path?
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed `/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml`, the path would be `/atlassian/bamboo/`

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

.GitHub v5.14
This page describes how to configure Bamboo to use a GitHub repository.

You can specify repositories at the following levels in Bamboo:
- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

Configure a GitHub source code repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose GitHub from the Source repository list.
4. Enter a Display Name to help identify the repository in Bamboo.
5. Enter your GitHub Username and Password.
6. Click Load Repositories.
7. You can configure the following advanced options for a GitHub source repository for your plan:

Advanced Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use submodules</td>
<td>Select to enable submodules support if these are defined for the repository. If native GitHub capability is not defined for agent submodules support will be disabled.</td>
</tr>
<tr>
<td>Command timeout</td>
<td>This is useful to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the GitHub repository.</td>
</tr>
<tr>
<td>Verbose logs</td>
<td>Turns on --verbose and --debug options in hg commands and passes the output to build logs. Use this option if you encounter problems with GitHub in Bamboo.</td>
</tr>
</tbody>
</table>
### Enable Quiet Period
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

### Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into **File Pattern** a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

### Exclude Changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

### Web Repository
If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

#### Stash
- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See [Integrating Bamboo with Bitbucket Server](#) for more information.

#### Fisheye
- **Fisheye URL** — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
- **Repository Name** — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See [Integrating Bamboo with Fisheye](#) for more information.

---

**.GitHub v6.1**

This page describes how to configure Bamboo to use a GitHub repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

### Configure a GitHub source code repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose GitHub from the Source repository list.
4. Enter a Display Name to help identify the repository in Bamboo.
5. Enter your GitHub Username and Password.
6. Click Load Repositories.
7. You can configure the following advanced options for a GitHub source repository for your plan:

#### Advanced Options

**Use submodules**
Select to enable submodules support if these are defined for the repository. If native GitHub capability is not defined for agent submodules support will be disabled.

**Command timeout**
This is useful to stop hung Bitbucket processes. On slower networks, you may consider increasing the default timeout to allow Bamboo time to make an initial clone of the GitHub repository.

**Verbose logs**
Turns on --verbose and --debug options in hg commands and passes the output to build logs. Use this option if you encounter problems with GitHub in Bamboo.

**Enable Quiet Period**
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

**Include/Exclude Files**
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

**Exclude Changesets**
Enter a regular expression to match the commit messages for changesets that should not start a build.

**Web Repository**

**Stash** – specify the following details for the repository:

- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.

**Fisheye** – specify the URL and other details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
- **Repository Name** — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

**How do I determine my Repository Path?**
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed /atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml, the path would be /atlassian/bamboo/.

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

**Mercurial**

---

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
This page describes how to configure Bamboo to use a Mercurial repository.

You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

**Before you start:**

- **Please use Mercurial 2.1.1 or later.** Mercurial 2.1 has a bug that makes it incompatible with Bamboo.
- You will not be able to create plans or jobs that use a Mercurial repository without specifying the shared local Mercurial capability first. Read more about [configuring a version control capability](#).

**Configure a Mercurial source repository**

1. Navigate to the repository configuration for a linked repository, plan or job. See [Linking to source code repositories](#).
2. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
3. Choose **Mercurial** from the **Source Repository** list.
4. Enter a **Name** to help identify the repository in Bamboo.
5. You can configure the following settings for a Mercurial source repository for your plan:

**Repository URL**

The full path to your Mercurial repository (eg: `git://bitbucket.org/atlassian/bamboo-git-plugin.git`)

Valid URLs are of the form:

- `local/filesystem/path[#revision]`
- `file:///local/filesystem/path[#revision]`
- `http[s]://[user[:pass]@]host[:port]/[path][#revision]`
- `ssh://[user[:pass]@]host[:port]/[path][#revision]`

For further references visit [Mercurial documentation](#).

**Branch**

The name of the relevant branch (or tag) you want to work on. Leave empty to work on default branch.

**Authentication**

- **Username and password**
  
  You can use shared credentials or type a username and a password.

- **SSH private key**
  
  You can use shared credentials or upload an SSH key and provide the SSH passphrase.

- **SSH private key (direct connection)**
  
  Upload an SSH Key. The passphrase is not required.

- **Default Mercurial credentials**
  
  Bamboo will rely on the default hg authentication. Use this option, for example, if you had set up the Bamboo server manually with SSH servers defined in `.ssh/config`, valid SSH identity files, etc.

**Advanced Options**

**Command timeout**

Type the number of minutes bamboo should wait for hg commands to finish. This is useful to stop hung Mercurial processes. On slower networks you may consider increasing default timeout to allow Bamboo to make an initial clone of the Mercurial repository.

**Verbose logs**

Turns on `--verbose` and `--debug` options in hg commands and passes the output to build logs. Use that option if you encounter problems with Mercurial in Bamboo.

**Location of POM file**

Type the path to your project’s pom.xml file which is relative to the root of your Mercurial Repository URL (defined above). Only available when importing a Maven 2 project.

**Disable repository caching**

Select this option to enable subrepositories support.

**Enable Quiet Period**

Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

Exclude Changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Web Repository
If your repository can be viewed in a web browser, select the repository type.
This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

Mercurial Web Repository – select one of the following viewer schemes:
  - BitBucket Web Repository Scheme (if you use BitBucket)
  - Default Web Repository Scheme (hgserve) (Mercurial's own default web server)

Stash – specify the following details for the repository:
  - Stash URL – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
  - Stash Project Key – the key of the project in Stash (e.g. 'CONF').
  - Repository Name – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.

Fisheye – specify the URL and other details for the repository:
  - Fisheye URL — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
  - Repository Name — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
  - Repository Path — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

How do I determine my Repository Path?
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed /atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml, the path would be /atlassian/bamboo/.

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

Upgrading remote agents for Mercurial
The remote agent installer has been modified for Bamboo 2.7 to handle Mercurial source code repositories. This update only impacts Mercurial plans or jobs that use the "SSH/Keyfile with passphrase" option to access the remote repository:

Screenshot: Choosing the 'Keyfile with passphrase' option for a plan or job
If you need to access a Mercurial repository using the SSH protocol with a passphrase-protected keyfile, then you need to upgrade your remote agents to version 2.7 or later. Otherwise, you can keep your old agent. To upgrade your remote agents:

1. Obtain the Bamboo remote agent for version 2.7 or later (i.e. atlassian-bamboo-agent-installer-x.x.jar where 'x.x' is 2.7 or later). Refer to Bamboo remote agent installation guide for more information.
2. Use this file to replace your existing atlassian-bamboo-agent-installer.x.x.jar (where 'x.x' is 2.6 or earlier) on the computers running your Bamboo remote agents.
3. Restart the remote agent (i.e. kill it among with accompanying wrapper processes and then issue the command 'java -jar atlassian-bamboo-agent-installer-2.7.jar yourBambooAgentServer').

This procedure should prepare your agent to build Mercurial plans using passphrase-protected SSH keyfiles.

Mercurial v5.14
This page describes how to configure Bamboo to use a Mercurial repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

Before you start:

- Please use Mercurial 2.1.1 or later. Mercurial 2.1 has a bug that makes it incompatible with Bamboo.
- You will not be able to create plans or jobs that use a Mercurial repository without specifying the shared local Mercurial capability first. Read more about configuring a version control capability.
Configure a Mercurial source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Mercurial from the Source Repository list.
4. Enter a Name to help identify the repository in Bamboo.
5. You can configure the following settings for a Mercurial source repository for your plan:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository URL</strong></td>
<td>The full path to your Mercurial repository (eg: git://bitbucket.org/atlassian/bamboo-git-plugin.git)</td>
</tr>
<tr>
<td></td>
<td>Valid URLs are of the form:</td>
</tr>
<tr>
<td></td>
<td>* local/filesystem/path[#revision]</td>
</tr>
<tr>
<td></td>
<td>* file://local/filesystem/path[#revision]</td>
</tr>
<tr>
<td></td>
<td>* http[s]://[user[:pass]@[host[:port]][/path][#revision]</td>
</tr>
<tr>
<td></td>
<td>* ssh://[user[:pass]@[host[:port]][/path][#revision]</td>
</tr>
<tr>
<td></td>
<td>(for further references visit Mercurial documentation)</td>
</tr>
<tr>
<td><strong>Branch</strong></td>
<td>The name of the relevant branch (or tag) you want to work on. Leave empty to work on default branch.</td>
</tr>
<tr>
<td><strong>Authentication</strong></td>

</tr>
</tbody>
</table>
Exclude Changesets

Enter a regular expression to match the commit messages for changesets that should not start a build.

Web Repository

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

Mercurial Web Repository – select one of the following viewer schemes:

- BitBucket Web Repository Scheme (if you use BitBucket)
- Default Web Repository Scheme (hgserve) (Mercurial's own default web server)

Stash – specify the following details for the repository:

- Stash URL – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- Stash Project Key – the key of the project in Stash (e.g. 'CONF').
- Repository Name – the name of the repository in Stash (e.g. 'conf-dev').

Fisheye – specify the URL and other details for the repository:

- Fisheye URL — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
- Repository Name — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- Repository Path — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Bitbucket Server for more information.

See Integrating Bamboo with Fisheye for more information.

Mercurial v6.1

This page describes how to configure Bamboo to use a Mercurial repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

Before you start:

- Please use Mercurial 2.1.1 or later. Mercurial 2.1 has a bug that makes it incompatible with Bamboo.
You will not be able to create plans or jobs that use a Mercurial repository without specifying the shared local Mercurial capability first. Read more about configuring a version control capability.

Configure a Mercurial source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Mercurial from the Source Repository list.
4. Enter a Name to help identify the repository in Bamboo.
5. You can configure the following settings for a Mercurial source repository for your plan:

Repository URL

The full path to your Mercurial repository (eg: git://bitbucket.org/atlassian/bamboo-git-plugin.git)

Valid URLs are of the form:

- local/filesystem/path[#revision]
- file://local/filesystem/path[#revision]
- http[s]://[user[:pass]@[host][:port]/[path][#revision]
- ssh://[user[:pass]@[host][:port]/[path][#revision]

For further references visit Mercurial documentation.

Branch

The name of the relevant branch (or tag) you want to work on. Leave empty to work on default branch.

Authentication

- **Username and password**
  You can use shared credentials or type a username and a password.
- **SSH private key**
  You can use shared credentials or upload an SSH key and provide the SSH passphrase.
- **SSH private key (direct connection)**
  Upload an SSH Key. The passphrase is not required.
- **Default Mercurial credentials**
  Bamboo will rely on the default hg authentication. Use this option, for example, if you had set up the Bamboo server manually with SSH servers defined in .ssh/config, valid SSH identity files, etc.

Advanced Options

Command timeout

Type the number of minutes bamboo should wait for hg commands to finish. This is useful to stop hung Mercurial processes. On slower networks you may consider increasing default timeout to allow Bamboo to make an initial clone of the Mercurial repository.

Verbose logs

Turns on --verbose and --debug options in hg commands and passes the output to build logs. Use that option if you encounter problems with Mercurial in Bamboo.

Location of POM file

Type the path to your project’s pom.xml file which is relative to the root of your Mercurial Repository URL (defined above). Only available when importing a Maven 2 project.

Disable repository caching

Select this option to enable subrepositories support.

Enable Quiet Period

Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

Include/Exclude Files

Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

Exclude Changesets

Enter a regular expression to match the commit messages for changesets that should not start a build.

Web Repository

If your repository can be viewed in a web browser, select the repository type.
This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

**Mercurial Web Repository** – select one of the following viewer schemes:

- **BitBucket Web Repository Scheme** (if you use BitBucket)
- **Default Web Repository Scheme** (Mercurial's own default web server)

**Stash** – specify the following details for the repository:

- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. `https://bitbucket.mycompany.com`).
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See [Integrating Bamboo with Bitbucket Server](#) for more information.

**Fisheye** – specify the URL and other details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. `https://atlassian.atlassian.com/`).
- **Repository Name** — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See [Integrating Bamboo with Fisheye](#) for more information.

**Perforce**

This page describes how to configure Bamboo to use a Perforce repository.

You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

**Configure a Perforce source repository**

1. Navigate to the repository configuration for a linked repository, plan or job. See [Linking to source code repositories](#).
2. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
3. Choose **Perforce** from the **Source Repository** list.
4. Enter a **Display Name** to help identify the repository in Bamboo.
5. You can configure the following settings for a Perforce source repository for your plan:

   **On this page:**
   - Configure a Perforce source repository
   - Notes

**Port**

Type either the port to which the Perforce client will connect, or the Perforce server itself. This is the Perforce P4PORT environment variable that tells Bamboo which p4d (Perforce server) to use.

**Client (Workspace)** (3)

The name of the Perforce Client Workspace which Bamboo will use. The Client Workspace determines which portions of the depot are visible in your Workspace Tree.

Do not create two Plans/Jobs that use the same client (e.g. one client set to manage, the other client set to not manage). This setup will create major issues in your builds.

**Depot View**

The client view of the depot that contains the source code files for this Plan/Job. This is typically in the form `/<clientname>/<workspace_mapping>/...`. For details please see the [Perforce User's Guide](#).
Bamboo sets the client root to its working directory, which means that code will be checked out to the 'working directory/<workspace_mapping>' location. Please take note of this, when specifying the 'Artifact Copy Pattern' for your Build Artifacts.)

**Username**
The Perforce username that Bamboo will use when it accesses the server ('Port'). Leave this field blank if you want Bamboo to use the default Perforce user (i.e. the OS username).

**Password**
Type the password required by the Perforce username (if applicable).

**Let Bamboo manage your workspace (4)**
This field indicates whether or not you want Bamboo to manage your workspace.

**Use Client Mapping For Change Detection**
Select this option if you use overlay mappings for your workspace. Your workspace must be available on the Bamboo Server

**Advanced Options**

**Enable Quiet Period**
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

**Include/Exclude Files**
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

**Exclude Changesets**
Enter a regular expression to match the commit messages for changesets that should not start a build.

**Web Repository**
If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

**Generic Web Repository**

- **Web Repository URL** – the URL of the repository.
- **Web Repository Module** — the particular repository required for this plan or job, if the Web Repository URL above points to multiple repositories.

**Stash – specify the following details for the repository:**

- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.

**Fisheye – specify the URL and other details for the repository:**

- **Fisheye URL** — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
- **Repository Name** — the name of your Fisheye repository (e.g. 'bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

**How do I determine my Repository Path?**
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed /atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml, the path would be /atlassian/bamboo/.

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

**Notes**

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
1. You will not be able to create plans or jobs that use a Perforce repository without specifying the shared local Perforce capability first. Read more about configuring a VCS capability.

2. Keep your Perforce configuration up to date — If you are using Perforce as your repository, you must ensure your Perforce configuration in Bamboo is in sync with any changes to your Perforce repository (such as client, depot or user credential changes). If not, your Perforce repository changes may cause unexpected behavior in Bamboo when Bamboo tries to access the repository. See the notes in the configuration instructions below for further details.

3. Issue when running Bamboo with Perforce prior to Bamboo 2.0.7 — A known issue exists when running Bamboo with Perforce prior to Bamboo 2.0.7 (See BAM-2866 and BAM-2849). If you change the name of your Perforce client (i.e. via an update) without updating your Perforce configuration in Bamboo, Bamboo will not be able to find the Perforce client to run against. Perforce will then create a default client in your running directory. This can lead to situations where Bamboo will attempt to clear out data from your running directory (e.g. force build). To avoid this problem, ensure that you update the 'Client' in your Perforce configuration whenever you change your Perforce client.

4. Please be aware of the following implications when either letting Bamboo manage or preventing Bamboo from managing your workspace:
   - **If you let Bamboo manage your workspace,**
     - We recommend this configuration if your Jobs will be running on many different machines or different operating systems, as Bamboo sets the client root for you.
     - Bamboo will make configuration changes to the Client Workspace to manage builds (e.g. Bamboo will modify the host and root). You need to ensure that you enter a Client Workspace in the 'Client' field that will be used solely for Bamboo.
     - Under this configuration, you should configure one client per Job to avoid conflicts when updating the client root.
   - **If you do not let Bamboo manage your workspace,**
     - We recommend this configuration if you wish to reuse your client for several Jobs, as Bamboo will retrieve the client root directory from Perforce and use it to run builds.

     **Setting the client root in Perforce:** We strongly recommend that you choose a directory that is dedicated for Bamboo’s use only, when you are specifying the client root in your Perforce repository. This directory may get cleaned (i.e. files and sub-directories deleted) if you choose to force clean builds.
     - Under this configuration, you need to ensure that the client root directory exists on all machines that the Job will be built on.
     - Please note that alternate roots does not currently work in Bamboo. See issue BAM-2377 for further details.

Using Perforce with Bamboo - limitations and workarounds

There are some limitations to using Bamboo with Perforce. Please read the following information carefully before setting up a build plan to use Perforce.

On this page:
1. Running builds on multiple remote agents or machines
2. Using Perforce Overlay and Exclusionary Mappings in Bamboo

1. Running builds on multiple remote agents or machines

**Limitation**

You will not be able to run builds on multiple remote agents and/or multiple remote machines using a Perforce repository, without using one of the workarounds described below. If you try to do so, you will run into problems with change detection that could cause your agents to build incorrect code. This problem does not affect the running of builds on multiple local agents.

**Background**

Perforce is a client/server SCM (software configuration management) system that manages your changes/files by storing the change information on its server. However, storing change information on the Perforce server can cause problems when you have clients on multiple agents/machines. If you have downloaded a particular change with a Perforce client, the change will be marked as downloaded by the Perforce server. If you use the same Perforce client on another machine, the Perforce server will incorrectly assume that you have already downloaded that particular change and will not download it. Hence, your agents may not pick up changes correctly and could build incorrect code.

**Workarounds**

There are a few workarounds available for this issue, if you are using Perforce with Bamboo:

- **Restrict your plan to use a single machine** — you can use one or more remote agents to build a plan, if they are running on the same machine and you set the client root yourself (i.e. do not let Bamboo manage your workspace) so that your agents will build to the same directory.
- **Make Bamboo force a clean build every time it builds** — this will ensure that your agents are always building the correct code. However, it can be an inefficient setup for big projects.
- **Use alternate roots for different machines** — specifying alternate roots for different machines will allow you to work around the change detection issue, as long as the roots on each machine are unique. Please note however, you will be restricted to three machines (with three different roots) due to Perforce limitations.

Please see the following Jira issues for further information, BAM-2843 and BAM-2774.

2. Using Perforce Overlay and Exclusionary Mappings in Bamboo
Limitation

You will not be able to control how Bamboo detects changes using exclusionary mappings or overlay mappings.

Please note, this issue does not affect you if you only trigger your builds on a schedule or manually, as Bamboo agents still build the correct code when triggered.

You may want to try the "Use Client Mapping For Change Detection" available in the Bamboo Perforce repository type.

Background

Bamboo currently uses the depot view, not the client view, when detecting changes. Hence, any exclusionary and overlay mappings will not be available during change detection.

For example, if a p4 client uses an overlay mapping like this one:

```
//depot/Prj/... //clientName/depot/Prj/...
+//depot/Dep/... //clientName/depot/Prj/Dep/...
```

and the 'Depot' specified in a plan's repository configuration is:

```
//clientName/depot/Prj/...
```

then Bamboo will lookup the corresponding depot view and detect changes by running the following command:

```
p4 changes //depot/Prj/...
```

Consequently, no changes to files in //clientName/depot/Prj/Dep/... will be picked up by change detection, despite the overlay mapping.

Hence, if you set up your build to trigger when code is updated it will not trigger correctly.

Workarounds

A partial workaround is available in Bamboo, if you wish to use exclusionary mappings for your client workspace. Specify your build plan to exclude files that match a specified pattern by choosing 'Exclude all changes that match the following pattern' from the 'Include / Exclude Files' dropdown (under the 'Common repository configuration' section). See this document for further details. Please note, this will only exclude one pattern whereas multiple exclusions can be specified in an exclusionary mapping.

Unfortunately, there is no workaround for overlay mappings in Bamboo.

Please note, we are aware of these problems and are working to address them — see the following Jira issue for further information, BAM-33.

Perforce v6.1

This page describes how to configure Bamboo to use a Perforce repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

Configure a Perforce source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Perforce from the Source Repository list.
4. Enter a Display Name to help identify the repository in Bamboo.
5. You can configure the following settings for a Perforce source repository for your plan:

   On this page:
   - Configure a Perforce source repository
   - Notes

Port

Type either the port to which the Perforce client will connect, or the Perforce server itself. This is the Perforce P4PORT environment variable that tells Bamboo which p4d (Perforce server) to use.
Client (Workspace) (3)
The name of the Perforce Client Workspace which Bamboo will use. The Client Workspace determines which portions of the depot are visible in your Workspace Tree.

Do not create two Plans/Jobs that use the same client (e.g. one client set to manage, the other client set to not manage). This setup will create major issues in your builds.

Depot View
The client view of the depot that contains the source code files for this Plan/Job. This is typically in the form //<clientname>/<workspace_mapping>/. . . For details please see the Perforce User's Guide.

Bamboo sets the client root to its working directory, which means that code will be checked out to the 'working directory/<workspace_mapping>' location. Please take note of this, when specifying the 'Artifact Copy Pattern' for your Build Artifacts.

Username
The Perforce username that Bamboo will use when it accesses the server ('Port'). Leave this field blank if you want Bamboo to use the default Perforce user (i.e. the OS username).

Password
Type the password required by the Perforce username (if applicable).

Let Bamboo manage your workspace (4)
This field indicates whether or not you want Bamboo to manage your workspace.

Use Client Mapping For Change Detection
Select this option if you use overlay mappings for your workspace. Your workspace must be available on the Bamboo Server

Advanced Options
Enable Quiet Period
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

Exclude Changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Web Repository
If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

Generic Web Repository
- Web Repository URL – the URL of the repository.
- Web Repository Module — the particular repository required for this plan or job, if the Web Repository URL above points to multiple repositories.

Stash – specify the following details for the repository:
- Stash URL – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- Stash Project Key – the key of the project in Stash (e.g. 'CONF').
- Repository Name – the name of the repository in Stash (e.g. 'conf-dev').

See Integrating Bamboo with Bitbucket Server for more information.

Fisheye – specify the URL and other details for the repository:
- Fisheye URL — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
- Repository Name — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- Repository Path — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

How do I determine my Repository Path?
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate...
root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk)). For example, if a code change listed /atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml, the path would be /atlassian/bamboo/.

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

Notes

1. You will not be able to create plans or jobs that use a Perforce repository without specifying the shared local Perforce capability first. Read more about configuring a VCS capability.
2. Keep your Perforce configuration up to date — If you are using Perforce as your repository, you must ensure your Perforce configuration in Bamboo is in sync with any changes to your Perforce repository (such as client, depot or user credential changes). If not, your Perforce repository changes may cause unexpected behavior in Bamboo when Bamboo tries to access the repository. See the notes in the configuration instructions below for further details.
3. Issue when running Bamboo with Perforce prior to Bamboo 2.0.7 — A known issue exists when running Bamboo with Perforce prior to Bamboo 2.0.7 (See BAM-2866 and BAM-2849). If you change the name of your Perforce client (i.e. via an update) without updating your Perforce configuration in Bamboo, Bamboo will not be able to find the Perforce client to run against. Perforce will then create a default client in your running directory. This can lead to situations where Bamboo will attempt to clear out data from your running directory (e.g. force build). To avoid this problem, ensure that you update the 'Client' in your Perforce configuration whenever you change your Perforce client.
4. Please be aware of the following implications when either letting Bamboo manage or preventing Bamboo from managing your workspace:
   - If you let Bamboo manage your workspace,
     - We recommend this configuration if your Jobs will be running on many different machines or different operating systems, as Bamboo sets the client root for you.
     - Bamboo will make configuration changes to the Client Workspace to manage builds (e.g. Bamboo will modify the host and root). You need to ensure that you enter a Client Workspace in the 'Client' field that will be used solely for Bamboo.
     - Under this configuration, you should configure one client per Job to avoid conflicts when updating the client root.
   - If you do not let Bamboo manage your workspace,
     - We recommend this configuration if you wish to reuse your client for several Jobs, as Bamboo will retrieve the client root directory from Perforce and use it to run builds.

⚠️ Setting the client root in Perforce: We strongly recommend that you choose a directory that is dedicated for Bamboo's use only, when you are specifying the client root in your Perforce repository. This directory may get cleaned (i.e. files and sub-directories deleted) if you choose to force clean builds.
- Under this configuration, you need to ensure that the client root directory exists on all machines that the Job will be built on.
- Please note that alternate roots does not currently work in Bamboo. See issue BAM-2377 for further details.

. Perforce v5.14

This page describes how to configure Bamboo to use a Perforce repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

Configure a Perforce source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Perforce from the Source Repository list.
4. Enter a Display Name to help identify the repository in Bamboo.
5. You can configure the following settings for a Perforce source repository for your plan:

<table>
<thead>
<tr>
<th>On this page:</th>
<th>Configure a Perforce source repository</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Type either the port to which the Perforce client will connect, or the Perforce server itself. This is the Perforce P4PORT environment variable that tells Bamboo which p4d (Perforce server) to use.</td>
<td></td>
</tr>
<tr>
<td>Client (Workspace)</td>
<td>The name of the Perforce Client Workspace which Bamboo will use. The Client Workspace determines which portions of the depot are visible in your Workspace Tree. Do not create two Plans/Jobs that use the same client (e.g. one client set to manage, the other client set to not manage). This setup will create major issues in your builds.</td>
<td></td>
</tr>
</tbody>
</table>
### Depot View

The client view of the depot that contains the source code files for this Plan/Job. This is typically in the form `//<clientname>/<workspace_mapping>/...` For details please see the Perforce User's Guide.

Bamboo sets the client root to its working directory, which means that code will be checked out to the working directory/<workspace_mapping> location. Please take note of this, when specifying the Artifact Copy Pattern for your Build Artifacts.

<table>
<thead>
<tr>
<th><strong>Username</strong></th>
<th>The Perforce username that Bamboo will use when it accesses the server ('Port'). Leave this field blank if you want Bamboo to use the default Perforce user (i.e. the OS username).</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Password</strong></td>
<td>Type the password required by the Perforce username (if applicable).</td>
</tr>
<tr>
<td><strong>Let Bamboo manage your workspace</strong></td>
<td>This field indicates whether or not you want Bamboo to manage your workspace.</td>
</tr>
<tr>
<td><strong>Use Client Mapping For Change Detection</strong></td>
<td>Select this option if you use overlay mappings for your workspace. Your workspace must be available on the Bamboo Server.</td>
</tr>
</tbody>
</table>

### Advanced Options

| **Enable Quiet Period** | Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build. |
| **Include/Exclude Files** | Allows you to specify the files that Bamboo should, or should not, use to detect changes. Enter into `File Pattern` a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples. |
| **Exclude Changesets** | Enter a regular expression to match the commit messages for changesets that should not start a build. |
| **Web Repository** | If your repository can be viewed in a web browser, select the repository type. This allows links to relevant files to be displayed in the 'Code Changes' section of a build result. |

#### Generic Web Repository

- **Web Repository URL** – the URL of the repository.
- **Web Repository Module** — the particular repository required for this plan or job, if the Web Repository URL above points to multiple repositories.

#### Stash

- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.
Fisheye – specify the URL and other details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. `https://atlaseye.atlassian.com/`).
- **Repository Name** — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See [Integrating Bamboo with Fisheye](#) for more information.

### How do I determine my Repository Path?
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when [browsing a repository](#) (e.g. `trunk`). For example, if a code change listed `/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml`, the path would be `/atlassian/bamboo/`.

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

### Notes

1. You will not be able to create plans or jobs that use a Perforce repository without specifying the shared local Perforce capability first. Read more about configuring a VCS capability.
2. Keep your Perforce configuration up to date — If you are using Perforce as your repository, you must ensure your Perforce configuration in Bamboo is in sync with any changes to your Perforce repository (such as client, depot or user credential changes). If not, your Perforce repository changes may cause unexpected behavior in Bamboo when Bamboo tries to access the repository. See the notes in the configuration instructions below for further details.
3. Issue when running Bamboo with Perforce prior to Bamboo 2.0.7 — A known issue exists when running Bamboo with Perforce prior to Bamboo 2.0.7 (See [BAM-2866](#) and [BAM-2849](#)). If you change the name of your Perforce client (i.e. via an update) without updating your Perforce configuration in Bamboo, Bamboo will not be able to find the Perforce client to run against. Perforce will then create a default client in your running directory. This can lead to situations where Bamboo will attempt to clear out data from your running directory (e.g. force build). To avoid this problem, ensure that you update the 'Client' in your Perforce configuration whenever you change your Perforce client.
4. Please be aware of the following implications when either letting Bamboo manage or preventing Bamboo from managing your workspace:
   - **If you let Bamboo manage your workspace,**
     - We recommend this configuration if your Jobs will be running on many different machines or different operating systems, as Bamboo sets the client root for you.
     - Bamboo will make configuration changes to the Client Workspace to manage builds (e.g. Bamboo will modify the host and root). You need to ensure that you enter a Client Workspace in the 'Client' field that will be used solely for Bamboo.
     - Under this configuration, you should configure one client per Job to avoid conflicts when updating the client root.
   - **If you do not let Bamboo manage your workspace,**
     - We recommend this configuration if you wish to reuse your client for several Jobs, as Bamboo will retrieve the client root directory from Perforce and use it to run builds.

> Setting the client root in Perforce: We strongly recommend that you choose a directory that is dedicated for Bamboo’s use only, when you are specifying the client root in your Perforce repository. This directory may get cleaned (i.e. files and sub-directories deleted) if you choose to force clean builds.

   - Under this configuration, you need to ensure that the client root directory exists on all machines that the Job will be built on.
   - Please note that alternate roots does not currently work in Bamboo. See issue [BAM-2377](#) for further details.

### Subversion

This page describes how to configure Bamboo to use a Subversion repository.

You can specify repositories at the following levels in Bamboo:

- **global** — repositories are available to all plans in Bamboo.
- **plan** — repositories are available to all jobs in the Bamboo plan.
- **job** — repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

On this page:

- Configure a Subversion source repository
- Notes
Configure a Subversion source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Subversion from the Source Repository list.
4. Enter a Display Name to help identify the repository in Bamboo.
5. You can configure the following settings for a Subversion source repository for your plan:

Repository URL
The location of the root of your Subversion repository. For example:

http://svn.collab.net/repos/svn/trunk

- Note that you can use global variables in this field (see Using Global or Build-specific Variables).

Branch name
The display name of a branch or a module that you want to check out. For example My project. The name will be used in the Bamboo UI.

Branch path
The path to a branch or a module that you want to checkout. For example, trunk, branches/my_branch. The path is relative to the root URL of the repository.

- Note that you can use global variables in this field (see Using Global or Build-specific Variables).

Username (Optional)
The Subversion username (if any) required to access the repository.

Authentication Type
- Password – choose this option if you want to authenticate with a username and password.
- SSH – if you choose to authenticate using SSH, you need to provide the following details:
  - Private Key — the absolute path of your SSH private key.
  - Passphrase — the passphrase for your SSH private key.

- Note that you are planning to use remote agents the ssh private key file has to be copied to the agent box into the same location as specified.

- SSL Client Certificate – if you choose to authenticate using an SSL Client Certificate, you need to provide the following details:
  - Private Key — the absolute path of your SSL client certificate.
  - Passphrase — the passphrase for your SSL client certificate.

- Please note, the client certificate has to be in PKCS12 format and the client certificate file must be passphrase protected, otherwise a runtime exception is thrown by the JDK security engine while opening the user key.

Advanced Options

Detect Changes in Externals
Select this if your Subversion repository uses svn:externals to link to other repositories (your externals must be in the root of the checkout directory, not in a subdirectory). Please note that you only need to select this check box if you require Bamboo to detect changes in the externals. If your externals reference a particular (static) revision, you do not need to check this box.

Use SVN Export
This option will speed up the first-time checkout, but updates are not supported. Implies Force Clean Build.

Enable Commit Isolation
Ensures that a build will only have one change, allowing you to isolate your build failures.

Automatically detect root URL for branches
Specifies whether the VCS Branching Task automatically determines the location of created branches.

Automatically detect root URL for tags
Specifies whether the VCS Tagging Task automatically determines the location of created branches.

Enable Quiet Period
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.
Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

Exclude Changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Web Repository
If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

Generic Web Repository
- Web Repository URL – the URL of the repository.
- Web Repository Module — the particular repository required for this plan or job, if the Web Repository URL above points to multiple repositories.

Stash – specify the following details for the repository:
- Stash URL – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- Stash Project Key – the key of the project in Stash (e.g. 'CONF').
- Repository Name – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.

Fisheye – specify the URL and other details for the repository:
- Fisheye URL — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
- Repository Name — the name of your Fisheye repository (e.g. 'bamboo'). This is effectively the alias for your repository path.
- Repository Path — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

How do I determine my Repository Path?
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed '/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml', the path would be /atlassian/bamboo/.

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

Notes
- If you are having problems connecting to Subversion, consult our documentation on troubleshooting Subversion connections.
- If you use pre-1.5 Subversion client to access code checked out by Bamboo, you may encounter problems with your builds. This is due to the SVNKit upgrade in Bamboo 2.1.4. Please read this knowledge base article for further details.
- You can add the -Dsvnkit.http.methods=Basic,NTLM system property to SVNKit to have NTLM authentication work with Bamboo.

Configuring source code management triggers for Subversion
This page provides instructions on how to configure Subversion to send message events that trigger the execution of Bamboo plans. You only need to configure Subversion to send these message events if the repository triggers the build when changes are committed build strategy has been specified for one or more of your Bamboo plans.

Configuring Subversion to trigger a build
This section explains how to configure Subversion to trigger a build when the repository is changed. A Subversion hook script is used to perform the trigger action whenever a Subversion repository is changed.

The following commands and script files assume that your Subversion server runs on a UNIX- or Linux-based operating system. If your Subversion server runs on any other operating system, then you will need to modify the script files and if necessary, the commands below to suit that operating system.
Step 1. Enable the Subversion post-commit hook

To do this, run the following commands:

```
  cd svn-repository-containing-the-build-source-code
  cd into the hooks/ directory
```

The Subversion post-commit file is not installed by default. If it does not exist, make a copy of the `post-commit.tmpl` file in the `hooks/` directory, name it `post-commit` and make it executable:

```
  cp post-commit.tmpl post-commit
  chmod a+rx post-commit
```

Step 2. Install the post-commit trigger

Add a line like the following to the `post-commit` file, for running Bamboo's build trigger script file.

```
/path-to-your-bamboo-installation/scripts/svn-triggers/postCommitBuildTrigger.sh base-url BUILD-KEY
```

where:

- `base-url` is the base URL of the Bamboo server. For example:
  - `http://<name-of-machine>:8085`
- `BUILD-KEY` is the key of the Bamboo plan to be executed.

Make Bamboo's build trigger script file executable (using `chmod`) so that the Subversion user can execute it.

Step 3. Do a test commit

Conduct a 'test' commit. Bamboo should start building the relevant plan after a few seconds.

The Bamboo log file should contain an entry like this:

```
[INFO] com.atlassian.bamboo.build.UpdateAndBuild - Bamboo build was triggered by remote http call from 127.0.0.1
```

Notes

Build Trigger Security — Bamboo will only accept remote build triggers if the triggers originated from the Subversion server(s) identified in the Subversion Repository URL of any Bamboo plans. Requests originating from other Subversion servers will be rejected by Bamboo.

Subversion v6.1

This page describes how to configure Bamboo to use a Subversion repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level — see Linking to source code repositories.
Configure a Subversion source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Subversion from the Source Repository list.
4. Enter a Display Name to help identify the repository in Bamboo.
5. You can configure the following settings for a Subversion source repository for your plan:

**Repository URL**
The location of the root of your Subversion repository. For example:

http://svn.collab.net/repos/svn

- Note that you can use global variables in this field (see Using Global or Build-specific Variables).
- If you are importing a Maven 2 Project, this location should contain your project’s pom.xml file.

**Branch name**
The display name of a branch or a module that you want to check out. For example My project. The name will be used in the Bamboo UI.

**Branch path**
The path to a branch or a module that you want to checkout. For example, trunk, branches/my_branch. The path is relative to the root URL of the repository.

- Note that you can use global variables in this field (see Using Global or Build-specific Variables).
- If you are importing a Maven 2 Project, this location should contain your project's pom.xml file.

**Username (Optional)**
The Subversion username (if any) required to access the repository.

**Authentication Type**
- **Password** – choose this option if you want to authenticate with a username and password.
- **SSH** – if you choose to authenticate using SSH, you need to provide the following details:
  - **Private Key** — the absolute path of your SSH private key.
  - **Passphrase** — the passphrase for your SSH private key.

- If you are planning to use remote agents the ssh private key file has to be copied to the agent box into the same location as specified.

- **SSL Client Certificate** – if you choose to authenticate using an SSL Client Certificate, you need to provide the following details:
  - **Private Key** — the absolute path of your SSL client certificate.
  - **Passphrase** — the passphrase for your SSL client certificate.

- Please note, the client certificate has to be in PKCS12 format and the client certificate file must be passphrase protected, otherwise a runtime exception is thrown by the JDK security engine while opening the user key.

**Advanced Options**

**Detect Changes in Externals**
Select this if your Subversion repository uses svn:externals to link to other repositories (your externals must be in the root of the checkout directory, not in a subdirectory). Please note that you only need to select this check box if you require Bamboo to detect changes in the externals. If your externals reference a particular (static) revision, you do not need to check this box.

**Use SVN Export**
This option will speed up the first-time checkout, but updates are not supported. Implies Force Clean Build.

**Enable Commit Isolation**
Ensures that a build will only have one change, allowing you to isolate your build failures.

**Automatically detect root URL for branches**
Specifies whether the VCS Branching Task automatically determines the location of created branches.

**Automatically detect root URL for tags**
Specifies whether the VCS Tagging Task automatically determines the location of created branches.

**Enable Quiet Period**
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.
Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into File Pattern a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

Exclude Changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Web Repository
If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

Generic Web Repository
- Web Repository URL – the URL of the repository.
- Web Repository Module — the particular repository required for this plan or job, if the Web Repository URL above points to multiple repositories.

Stash – specify the following details for the repository:
- Stash URL – the URL of your Stash instance (e.g. 'https://bitbucket.mycompany.com').
- Stash Project Key – the key of the project in Stash (e.g. 'CONF').
- Repository Name – the name of the repository in Stash (e.g. 'conf-dev').

See Integrating Bamboo with Bitbucket Server for more information.

Fisheye – specify the URL and other details for the repository:
- Fisheye URL — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
- Repository Name — the name of your Fisheye repository (e.g. 'bamboo'). This is effectively the alias for your repository path.
- Repository Path — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

How do I determine my Repository Path?
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed '/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml', the path would be '/atlassian/bamboo/

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

Notes
- If you are having problems connecting to Subversion, consult our documentation on troubleshooting Subversion connections.
- If you use a pre-1.5 Subversion client to access code checked out by Bamboo, you may encounter problems with your builds. This is due to the SVNKit upgrade in Bamboo 2.1.4. Please read this knowledge base article for further details.
- You can add the -Dsvnkit.http.methods=Basic,NTLM system property to SVNKit to have NTLM authentication work with Bamboo.

Subversion v5.14
This page describes how to configure Bamboo to use a Subversion repository.

You can specify repositories at the following levels in Bamboo:
- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

<tr>
<td>Repository Name</td>
<td>the name of the repository in Stash (e.g. 'conf-dev').</td>
</tr>
<tr>
<td>Use this option to connect to a Bitbucket Server repository.</td>
<td></td>
</tr>
</tbody>
</table>

See Integrating Bamboo with Bitbucket Server for more information.
Fisheye – specify the URL and other details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. 'https://atlasEye.atlassian.com/').
- **Repository Name** — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See [Integrating Bamboo with Fisheye](#) for more information.

### How do I determine my Repository Path?

If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed /atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml, the path would be /atlassian/bamboo/. If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

#### Notes

- If you are having problems connecting to Subversion, consult our documentation on troubleshooting Subversion connections.
- If you use pre-1.5 Subversion client to access code checked out by Bamboo, you may encounter problems with your builds. This is due to the SVNKit upgrade in Bamboo 2.1.4. Please read this [knowledge base article](#) for further details.
- You can add the -Dsvnkit.http.methods=Basic,NTLM system property to SVNKit to have NTLM authentication work with Bamboo.

### .Subversion v6.4

This page describes how to configure Bamboo to use a Subversion repository.

You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

### On this page:

- Configure a Subversion source repository
- Notes

### Related pages:

- Setting the SVN workspace format

### Configure a Subversion source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See [Linking to source code repositories](#).
2. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
3. Choose **Subversion** from the **Source Repository** list.
4. Enter a **Display Name** to help identify the repository in Bamboo.
5. You can configure the following settings for a Subversion source repository for your plan:

#### Repository URL

The location of the root of your Subversion repository. For example:

http://svn.collab.net/repos/svn

- Note that you can use global variables in this field (see [Using Global or Build-specific Variables](#)).
- If you are importing a Maven 2 Project, this location should contain your project's `pom.xml` file.

#### Branch name

Created by Atlassian in 2018. Licensed under a [Creative Commons Attribution 2.5 Australia License](#).
The display name of a branch or a module that you want to check out. For example, \textit{My project}. The name will be used in the Bamboo UI.

\textbf{Branch path}

The path to a branch or a module that you want to checkout. For example, \textit{trunk, branches/my\_branch}. The path is relative to the root URL of the repository.

\begin{itemize}
\item Note that you can use global variables in this field (see Using Global or Build-specific Variables).
\item If you are importing a Maven 2 Project, this location should contain your project's \texttt{pom.xml} file.
\end{itemize}

\textbf{Username (Optional)}

The Subversion username (if any) required to access the repository.

\textbf{Authentication Type}

\begin{itemize}
\item \textbf{Password} – choose this option if you want to authenticate with a username and password.
\item \textbf{SSH} – if you choose to authenticate using SSH, you need to provide the following details:
  \begin{itemize}
  \item \textbf{Private Key} — the absolute path of your SSH private key.
  \item \textbf{Passphrase} — the passphrase for your SSH private key.
  \end{itemize}
  \begin{itemize}
  \item If you are planning to use remote agents the \texttt{ssh private key} file has to be copied to the agent box into the same location as specified.
  \end{itemize}
\item \textbf{SSL Client Certificate} – if you choose to authenticate using an SSL Client Certificate, you need to provide the following details:
  \begin{itemize}
  \item \textbf{Private Key} — the absolute path of your SSL client certificate.
  \item \textbf{Passphrase} — the passphrase for your SSL client certificate.
  \end{itemize}
  \begin{itemize}
  \item Please note, the client certificate has to be in PKCS12 format and the client certificate file must be passphrase protected, otherwise a runtime exception is thrown by the JDK security engine while opening the user key.
  \end{itemize}
\end{itemize}

\textbf{Advanced Options}

\textbf{Detect Changes in Externals}

Select this if your Subversion repository uses \texttt{svn:externals} to link to other repositories (your externals must be in the root of the checkout directory, not in a subdirectory). Please note that you only need to select this check box if you require Bamboo to detect changes in the externals. If your externals reference a particular (static) revision, you do not need to check this box.

\textbf{Use SVN Export}

This option will speed up the first-time checkout, but updates are not supported. Implies Force Clean Build.

\textbf{Enable Commit Isolation}

Ensures that a build will only have one change, allowing you to isolate your build failures.

\textbf{Automatically detect root URL for branches}

Specifies whether the VCS Branching Task automatically determines the location of created branches.

\textbf{Automatically detect root URL for tags}

Specifies whether the VCS Tagging Task automatically determines the location of created branches.

\textbf{Enable Quiet Period}

Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

\textbf{Include/Exclude Files}

Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into \texttt{File Pattern} a \texttt{regular expression} to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See \texttt{sub page} for examples.

\textbf{Exclude Changesets}

Enter a \texttt{regular expression} to match the commit messages for changesets that should not start a build.

\textbf{Web Repository}

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

\textbf{Generic Web Repository}

\begin{itemize}
\item \textbf{Web Repository URL} – the URL of the repository.
\item \textbf{Web Repository Module} — the particular repository required for this plan or job, if the Web Repository URL above points to multiple repositories.
\end{itemize}

\textbf{Stash} – specify the following details for the repository:

\begin{itemize}
\item \textbf{Stash URL} – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
\item \textbf{Stash Project Key} – the key of the project in Stash (e.g. 'CONF').
\item \textbf{Repository Name} – the name of the repository in Stash (e.g. 'conf-dev').
\end{itemize}

Use this option to connect to a Bitbucket Server repository.
See Integrating Bamboo with Bitbucket Server for more information.

**Fisheye** – specify the URL and other details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. `https://atlaseye.atlassian.com/`).
- **Repository Name** — the name of your Fisheye repository (e.g. `bamboo`). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. `'/atlassian/bamboo/`).

See Integrating Bamboo with Fisheye for more information.

### How do I determine my Repository Path?
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. `trunk`). For example, if a code change listed `/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml`, the path would be `/atlassian/bamboo/.

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

### Notes
- If you are having problems connecting to Subversion, consult our documentation on troubleshooting Subversion connections.
- If you use the pre-1.5 Subversion client to access code checked out by Bamboo, you may encounter problems with your builds. This is due to the SVNKit upgrade in Bamboo 2.1.4. Please read this knowledge base article for further details.
- You can add the `-Dsvnkit.http.methods=Basic,NTLM` system property to SVNKit to have NTLM authentication work with Bamboo.

### Subversion v6.3
This page describes how to configure Bamboo to use a Subversion repository.

You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

**On this page:**

### Configure a Subversion source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose Subversion from the Source Repository list.
4. Enter a Display Name to help identify the repository in Bamboo.
5. You can configure the following settings for a Subversion source repository for your plan:

#### Repository URL
The location of the root of your Subversion repository. For example:

`http://svn.collab.net/repos/svn`

- **Note** that you can use global variables in this field (see Using Global or Build-specific Variables).
- **Note** if you are importing a Maven 2 Project, this location should contain your project's pom.xml file.

#### Branch name
The display name of a branch or a module that you want to check out. For example, `My project`. The name will be used in the Bamboo UI.

#### Branch path
The path to a branch or a module that you want to checkout. For example, `trunk`, `branches/my_branch`. The path is relative to the root URL of the repository.
**Note that you can use global variables in this field (see Using Global or Build-specific Variables).**

If you are importing a Maven 2 Project, this location should contain your project's `pom.xml` file.

**Username** (Optional)
The Subversion username (if any) required to access the repository.

**Authentication Type**
- **Password** – choose this option if you want to authenticate with a username and password.
- **SSH** – if you choose to authenticate using SSH, you need to provide the following details:
  - **Private Key** — the absolute path of your SSH private key.
  - **Passphrase** — the passphrase for your SSH private key.

  If you are planning to use remote agents the `ssh private key` file has to be copied to the agent box into the same location as specified.

- **SSL Client Certificate** – if you choose to authenticate using an SSL Client Certificate, you need to provide the following details:
  - **Private Key** — the absolute path of your SSL client certificate.
  - **Passphrase** — the passphrase for your SSL client certificate.

  Please note, the client certificate has to be in PKCS12 format and the client certificate file must be passphrase protected, otherwise a runtime exception is thrown by the JDK security engine while opening the user key.

**Advanced Options**

**Detect Changes in Externals**
Select this if your Subversion repository uses `svn:externals` to link to other repositories (your externals must be in the root of the checkout directory, not in a subdirectory). Please note that you only need to select this check box if you require Bamboo to detect changes in the externals. If your externals reference a particular (static) revision, you do not need to check this box.

**Use SVN Export**
This option will speed up the first-time checkout, but updates are not supported. Implies Force Clean Build.

**Enable Commit Isolation**
Ensures that a build will only have one change, allowing you to isolate your build failures.

**Automatically detect root URL for branches**
Specifies whether the VCS Branching Task automatically determines the location of created branches.

**Automatically detect root URL for tags**
Specifies whether the VCS Tagging Task automatically determines the location of created branches.

**Enable Quiet Period**
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

**Include/Exclude Files**
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into `File Pattern` a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

**Exclude Changesets**
Enter a regular expression to match the commit messages for changesets that should not start a build.

**Web Repository**
If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

**Generic Web Repository**
- **Web Repository URL** – the URL of the repository.
- **Web Repository Module** — the particular repository required for this plan or job, if the Web Repository URL above points to multiple repositories.

**Stash** – specify the following details for the repository:
- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See Integrating Bamboo with Bitbucket Server for more information.
Fisheye — specify the URL and other details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. `https://atlaseye.atlassian.com/`).
- **Repository Name** — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

---

### How do I determine my Repository Path?

If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to

1. View the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed `/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml`, the path would be `/atlassian/bamboo/`.

2. If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

---

### Notes

- If you are having problems **connecting to Subversion**, consult our documentation on **troubleshooting Subversion connections**.
- If you use a pre-1.5 Subversion client to access code checked out by Bamboo, you may encounter problems with your builds. This is due to the SVNKit upgrade in Bamboo 2.1.4. Please read this [knowledge base article](#) for further details.
- You can add the `-Dsvnkit.http.methods=Basic,NTLM` system property to SVNKit to have NTLM authentication work with Bamboo.

---

### Subversion v6.2

This page describes how to configure Bamboo to use a Subversion repository.

You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

#### On this page:

- Configure a Subversion source repository
- Notes

#### Related pages:

- Setting the SVN workspace format

---

### Configure a Subversion source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See [Linking to source code repositories](#).
2. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
3. Choose **Subversion** from the **Source Repository** list.
4. Enter a **Display Name** to help identify the repository in Bamboo.
5. You can configure the following settings for a Subversion source repository for your plan:

#### Repository URL

The location of the root of your Subversion repository. For example:

```
http://svn.collab.net/repos/svn
```

- Note that you can use global variables in this field (see [Using Global or Build-specific Variables](#)).

#### Branch name

The display name of a branch or a module that you want to check out. For example **My project**. The name will be used in the Bamboo UI.

#### Branch path

The path to a branch or a module that you want to checkout. For example, **trunk**, **branches/my_branch**. The path is relative to the root URL of the repository.

- Note that you can use global variables in this field (see [Using Global or Build-specific Variables](#)).

---

### Username (Optional)
The Subversion username (if any) required to access the repository.

Authentication Type

- **Password** – choose this option if you want to authenticate with a username and password.
- **SSH** – if you choose to authenticate using SSH, you need to provide the following details:
  - **Private Key** — the absolute path of your SSH private key.
  - **Passphrase** — the passphrase for your SSH private key.

  If you are planning to use remote agents the **ssh private key** file has to be copied to the agent box into the same location as specified.

- **SSL Client Certificate** – if you choose to authenticate using an SSL Client Certificate, you need to provide the following details:
  - **Private Key** — the absolute path of your SSL client certificate.
  - **Passphrase** — the passphrase for your SSL client certificate.

Please note, the client certificate has to be in PKCS12 format and the client certificate file must be passphrase protected, otherwise a runtime exception is thrown by the JDK security engine while opening the user key.

Advanced Options

**Detect Changes in Externals**
Selected this if your Subversion repository uses `svn:externals` to link to other repositories (your externals must be in the root of the checkout directory, not in a subdirectory). Please note that you only need to select this check box if you require Bamboo to detect changes in the externals. If your externals reference a particular (static) revision, you do not need to check this box.

**Use SVN Export**
This option will speed up the first-time checkout, but updates are not supported. Implies Force Clean Build.

**Enable Commit Isolation**
Ensures that a build will only have one change, allowing you to isolate your build failures.

**Automatically detect root URL for branches**
Specifies whether the VCS Branching Task automatically determines the location of created branches.

**Automatically detect root URL for tags**
Specifies whether the VCS Tagging Task automatically determines the location of created branches.

**Enable Quiet Period**
Specifies a delay after a single commit is detected before the build is started. This allows multiple commits to be aggregated into a single build.

**Include/Exclude Files**
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into **File Pattern** a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See [sub page](#) for examples.

**Exclude Changesets**
Enter a regular expression to match the commit messages for changesets that should not start a build.

**Web Repository**
If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

**Generic Web Repository**

- **Web Repository URL** – the URL of the repository.
- **Web Repository Module** — the particular repository required for this plan or job, if the Web Repository URL above points to multiple repositories.

**Stash** – specify the following details for the repository:

- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. 'https://bitbucket.mycompany.com').
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** — the name of the repository in Stash (e.g. 'conf-dev').

Use this option to connect to a Bitbucket Server repository.

See [Integrating Bamboo with Bitbucket Server](#) for more information.

**Fisheye** – specify the URL and other details for the repository:

- **Fisheye URL** — the URL of your Fisheye repository (e.g. 'https://atlaseye.atlassian.com/').
- **Repository Name** — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
• Repository Path — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.

**How do I determine my Repository Path?**
If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed /atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml, the path would be /atlassian/bamboo/.
If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

**Notes**
- If you are having problems connecting to Subversion, consult our documentation on troubleshooting Subversion connections.
- If you use pre-1.5 Subversion client to access code checked out by Bamboo, you may encounter problems with your builds. This is due to the SVNKit upgrade in Bamboo 2.1.4. Please read this knowledge base article for further details.
- You can add the -Dsvnkit.http.methods=Basic,NTLM system property to SVNKit to have NTLM authentication work with Bamboo.

**CVS**
This page describes how to configure Bamboo to use a Bitbucket repository.

You can specify repositories at the following levels in Bamboo:
- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

**Configure a CVS source repository**

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose CVS from the Source Repository list.
4. Enter a Display Name to help identify the repository in Bamboo.
5. You can configure the following settings for a CVS source repository for your plan:

**CVS Root**
The full path to your CVS repository root (e.g. :pserver:me@cvs.atlassian.com:/cvsroot/atlassian ). Bamboo supports pserver, ext (ssh) and local repository access methods. Note that you can use global variables in this field (see Bamboo variables).

If you are importing a Maven 2 Project, this location should contain your project's pom.xml file.

**Authentication Type**
- Password – choose this option if you want to authenticate with a password.
- SSH – if you choose to authenticate using SSH, you need to provide the following details:
  - Private Key — the absolute path of your SSH private key.
  - Passphrase — the passphrase for your SSH private key.

**Quiet Period**
This setting is used to avoid starting a build while someone is in mid-checkin. Bamboo will only initiate a build for this plan when no more changes are detected within the Quiet Period following the last known change. Type the number of seconds Bamboo should wait. Please note that this parameter is mandatory for CVS, as CVS allows partial checkouts.

(Only available when configuring an existing plan.)

**Module**
The name of the CVS module that contains the source-code.

Currently Bamboo has limited support for CVS ampersand modules. To use an ampersand module, you will need to define a regular module with the same name as the ampersand module (since Bamboo expects there to be a directory with the specified checkout module name). For example:
- a. Create a module (e.g. allbuilds).
- b. Define an ampersand module with the same name. (The ampersand module can be empty.)
- c. In the Module field, enter the following: allbuilds allbuilds &project2 &project2 &project3

**Version of module**
The version of the module that Bamboo should build:
- HEAD
• **Branch/Tag** – supply the name of the branch or tag.

ℹ️ Note that you can use global variables in this field (see Bamboo variables).

### Advanced Options

#### Include/Exclude Files

Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into **File Pattern** a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

#### Exclude Changesets

Enter a regular expression to match the commit messages for changesets that should not start a build.

#### Web Repository

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

- **Generic Web Repository**
  - Web Repository URL – the URL of the repository.
  - Web Repository Module — the particular repository required for this plan or job, if the Web Repository URL above points to multiple repositories.

- **Stash** – specify the following details for the repository:
  - Stash URL – the URL of your Stash (now Bitbucket Server) instance (e.g. `https://bitbucket.mycompany.com`).
  - Stash Project Key — the key of the project in Stash (e.g. 'CONF').
  - Repository Name — the name of the repository in Stash (e.g. 'conf-dev').

See Integrating Bamboo with Bitbucket Server for more information.

Use this option to connect to a Bitbucket Server repository.

#### Fisheye

- Fisheye URL — the URL of your Fisheye repository (e.g. `https://atlaseye.atlassian.com/`).
- Repository Name — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- Repository Path — the path for your Fisheye repository (e.g. `/atlassian/bamboo/`).

See Integrating Bamboo with Fisheye for more information.

- **How do I determine my Repository Path?**

  If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. `trunk`). For example, if a code change listed `/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml`, the path would be `/atlassian/bamboo/`. If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

### Configuring source code management triggers for CVS

This page provides instructions on how to configure CVS to send message events that trigger the execution of Bamboo plans.

You only need to configure CVS to send these message events if the repository triggers the build when changes are committed trigger has been configured for one or more of your Bamboo plans.

#### Configuring CVS to trigger a build

This section explains how to configure CVS to trigger a build when the repository is changed. This involves installing two scrips:

1. A pre-commit trigger keeps track of the last directory to be processed, so we know when the commit has completed.
2. A post-commit trigger that waits until it has processed the last directory of the commit before instructing the Bamboo server to execute the relevant plan(s).

**On this page:**
- Configuring CVS to trigger a build
- Notes
The following commands and script files assume that your CVS server runs on a UNIX- or Linux-based operating system. If your CVS server runs on any other operating system, then you will need to modify the script files and if necessary, the commands below to suit that operating system.

Step 1. Checking out the CVSROOT

First check out your repository's CVSROOT directory into a temporary directory:

```bash
cvs -d cvsroot-to-your-repository checkout CVSROOT
```

where:

- `cvsroot-to-your-repository` is the root directory pathname of the CVS repository.
- `cvs` overrides the any `$CVSROOT` environment variable setting.

The following files should be checked out:

- `CVSROOT/checkoutlist`
- `CVSROOT/commitinfo`
- `CVSROOT/config`
- `CVSROOT/cvswrappers`
- `CVSROOT/editinfo`
- `CVSROOT/loginfo`
- `CVSROOT/modules`
- `CVSROOT/notify`
- `CVSROOT/rcsinfo`
- `CVSROOT/taginfo`
- `CVSROOT/verifymsg`

Step 2. Install the pre-commit trigger

Add a line like the following example's to the `CVSROOT/commitinfo` pre-commit trigger file. The `CVSROOT/commitinfo` file contains the list of programs to run whenever a file is about to be committed to the repository.

```bash
^Moo /path-to-your-bamboo-installation/scripts/cvs-triggers/preCommit.sh %r/%p
```

where:

- `^Moo` is the regular expression used to identify the name of the module (called Moo) being updated.
- `/path-to-your-bamboo-installation/scripts/cvs-triggers/preCommit.sh` is the Bamboo shell script used to detect the last file of the check in.
- If your Bamboo installation and CVS server are on different machines, refer to the note below.

Step 3. Install the post-commit trigger

Add a line like the following example's to the `CVSROOT/loginfo` post-commit trigger file. The `CVSROOT/loginfo` file contains the list of programs to run whenever a file has been successfully committed into the repository.

```bash
^Moo /path-to-your-bamboo-installation/scripts/cvs-triggers/postCommitBuildTrigger.sh %r/%p http://bamboo-base-url MOO-KEY
```

where:
• "Moo" is the regular expression used to identify the name of the module (called Moo) being updated.
• /path-to-your-bamboo-installation/scripts/cvs-triggers/postCommitBuildTrigger.sh is the Bamboo shell script to trigger the build.
  - If your Bamboo installation and CVS server are on different machines, refer to the note below.
• $CVSROOT path is how CVS tells the postCommitBuildTrigger.sh script which directory it is committing.
• http://bamboo-base-url is the URL of the Bamboo server.
• MOO-KEY the key of the Bamboo plan to be executed.

Step 4. Save the changes back to CVS

Commit the changes you made to CVSROOT/commitinfo and CVSROOT/loginfo files in step 2 and 3, respectively, back to the repository.

```
cvs -d cvsroot-to-your-repository commit
```

where:

• cvsroot-to-your-repository is the root directory pathname of the CVS repository.
  - Using -d cvsroot-to-your-repository overrides the any $CVSROOT environment variable setting.

Step 5. Do a test commit

Conduct a 'test' commit. Bamboo should start building the relevant plan after a few seconds.

The Bamboo log file should contain an entry like this:

```
[INFO] com.atlassian.bamboo.build.UpdateAndBuild - Bamboo build was triggered by remote http call from 127.0.0.1
```

- The postCommitBuildTrigger.sh is only triggered when the last file of the commit has been committed.
- The preCommit.sh and postCommitBuildTrigger.sh must have sufficient privileges to be executed by the CVS user.
- If your Bamboo installation is not running on the same machine as the CVS server, you will also need add the Bamboo preCommit.sh and postCommitBuildTrigger.sh files to the CVSROOT directory and add the names of these files to the end of the checkoutlist file.

Notes

Build Trigger Security — Bamboo will only accept remote build triggers if the triggers originated from the CVS server(s) identified in the CVSROOT paths of any Bamboo plans. Requests originating from other CVS servers will be rejected by Bamboo.

CVS v6.1

This page describes how to configure Bamboo to use a Bitbucket repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

Configure a CVS source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Either click Add Repository to add a new repository, or edit an existing repository configuration.
3. Choose CVS from the Source Repository list.
4. Enter a Display Name to help identify the repository in Bamboo.
5. You can configure the following settings for a CVS source repository for your plan:

CVS Root

The full path to your CVS repository root (e.g. :pserver:me@cvs.atlassian.com:/cvsroot/atlassian ). Bamboo supports pserver, ext (ssh) and local repository access methods. Note that you can use global variables in this field (see Bamboo variables).

- If you are importing a Maven 2 Project, this location should contain your project's pom.xml file.
Authentication Type
- **Password** – choose this option if you want to authenticate with a password.
- **SSH** – if you choose to authenticate using SSH, you need to provide the following details:
  - **Private Key** — the absolute path of your SSH private key.
  - **Passphrase** — the passphrase for your SSH private key.

Quiet Period
This setting is used to avoid starting a build while someone is in mid-checkin. Bamboo will only initiate a build for this plan when no more changes are detected within the Quiet Period following the last known change. Type the number of seconds Bamboo should wait. Please note that this parameter is mandatory for CVS, as CVS allows partial checkouts.

*(Only available when configuring an existing plan.)*

Module
Type the name of the CVS module that contains the source-code.

Currently Bamboo has limited support for CVS ampersand modules. To use an ampersand module, you will need to define a regular module with the same name as the ampersand module (since Bamboo expects there to be a directory with the specified checkout module name). For example:

a. Create a module (e.g. `allbuilds`).

b. Define an ampersand module with the same name. (The ampersand module can be empty.)

c. In the **Module** field, enter the following: `allbuilds allbuilds &project2 &project2 &project3`

Version of module
The version of the module that Bamboo should build:

- **HEAD**
- **Branch/Tag** – supply the name of the branch or tag.

*Note that you can use global variables in this field (see Bamboo variables).*

Advanced Options

Include/Exclude Files
Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into **File Pattern** a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

Exclude Changesets
Enter a regular expression to match the commit messages for changesets that should not start a build.

Web Repository
If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the 'Code Changes' section of a build result.

Generic Web Repository

- **Web Repository URL** – the URL of the repository.
- **Web Repository Module** — the particular repository required for this plan or job, if the Web Repository URL above points to multiple repositories.

Stash – specify the following details for the repository:

- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. `https://bitbucket.mycompany.com`).
- **Stash Project Key** – the key of the project in Stash (e.g. 'CONF').
- **Repository Name** – the name of the repository in Stash (e.g. 'conf-dev').

See Integrating Bamboo with Bitbucket Server for more information.

Fisheye

- **Fisheye URL** — the URL of your Fisheye repository (e.g. `https://atlaseye.atlassian.com/`).
- **Repository Name** — the name of your Fisheye repository (e.g. 'Bamboo'). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. '/atlassian/bamboo/').

See Integrating Bamboo with Fisheye for more information.
This page describes how to configure Bamboo to use a Bitbucket repository.

You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).

### Configure a CVS source repository

1. Navigate to the repository configuration for a linked repository, plan or job. See [Linking to source code repositories](#).
2. Either click **Add Repository** to add a new repository, or edit an existing repository configuration.
3. Choose **CVS** from the **Source Repository** list.
4. Enter a **Display Name** to help identify the repository in Bamboo.
5. You can configure the following settings for a CVS source repository for your plan:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVS Root</td>
<td>The full path to your CVS repository root (e.g. <code>pserver:me@cvs.atlassian.com:/cvsroot/atlassian</code>). Bamboo supports pserver, ext (ssh) and local repository access methods. Note that you can use global variables in this field (see <a href="#">Bamboo variables</a>).</td>
</tr>
<tr>
<td>Authentication Type</td>
<td>Password – choose this option if you want to authenticate with a password.</td>
</tr>
<tr>
<td></td>
<td>SSH – if you choose to authenticate using SSH, you need to provide the following details:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Private Key</strong> — the absolute path of your SSH private key.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Passphrase</strong> — the passphrase for your SSH private key.</td>
</tr>
<tr>
<td>Quiet Period</td>
<td>This setting is used to avoid starting a build while someone is in mid-checkin. Bamboo will only initiate a build for this plan when no more changes are detected within the Quiet Period following the last known change. Type the number of seconds Bamboo should wait. Please note that this parameter is mandatory for CVS, as CVS allows partial checkouts.</td>
</tr>
<tr>
<td></td>
<td><em>(Only available when configuring an existing plan)</em></td>
</tr>
<tr>
<td>Module</td>
<td>Type the name of the CVS module that contains the source-code.</td>
</tr>
</tbody>
</table>

Currently Bamboo has limited support for CVS ampersand modules. To use an ampersand module, you will need to define a regular module with the same name as the ampersand module (since Bamboo expects there to be a directory with the specified checkout module name). For example:

- a. Create a module (e.g. `allbuilds`).
- b. Define an ampersand module with the same name. *(The ampersand module can be empty.)*
- c. In the **Module** field, enter the following: `allbuilds allbuilds &project2 &project2 &project3`

### How do I determine my Repository Path?

If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to **view the code changes** and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when **browsing a repository** (e.g. **trunk**). For example, if a code change listed `/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml`, the path would be `/atlassian/bamboo/`

If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

**CVS v5.14**

This page describes how to configure Bamboo to use a Bitbucket repository.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see [Linking to source code repositories](#).
### Version of module

The version of the module that Bamboo should build:

- **HEAD**
- **Branch/Tag** – supply the name of the branch or tag.

Note that you can use global variables in this field (see Bamboo variables).

### Advanced Options

#### Include/Exclude Files

Allows you to specify the files that Bamboo should, or should not, use to detect changes.

Enter into **File Pattern** a regular expression to match the files that Bamboo includes or excludes. The regex pattern must match the file path in the repository. See sub page for examples.

#### Exclude Changesets

Enter a regular expression to match the commit messages for changesets that should not start a build.

### Web Repository

If your repository can be viewed in a web browser, select the repository type.

This allows links to relevant files to be displayed in the ‘Code Changes’ section of a build result.

**Generic Web Repository**

- **Web Repository URL** – the URL of the repository.
- **Web Repository Module** — the particular repository required for this plan or job, if the **Web Repository URL** above points to multiple repositories.

**Stash** – specify the following details for the repository:

- **Stash URL** – the URL of your Stash (now Bitbucket Server) instance (e.g. ‘https://bitbucket.mycompany.com’).
- **Stash Project Key** – the key of the project in Stash (e.g. ‘CONF’).
- **Repository Name** – the name of the repository in Stash (e.g. ‘conf-dev’).

See Integrating Bamboo with Bitbucket Server for more information.

Use this option to connect to a Bitbucket Server repository.
Fisheye

- **Fisheye URL** — the URL of your Fisheye repository (e.g. `https://atlaseye.atlassian.com/`).
- **Repository Name** — the name of your Fisheye repository (e.g. `bamboo`). This is effectively the alias for your repository path.
- **Repository Path** — the path for your Fisheye repository (e.g. `/atlassian/bamboo/`).

See [Integrating Bamboo with Fisheye](#) for more information.

### How do I determine my Repository Path?

If you have previously run builds with changes from your repository, the easiest way of determining your repository path is to view the code changes and copy the path from the start of the path of one of the changed files, up to (but not including) the appropriate root directory. The root directories for repositories are the ones shown by Fisheye when browsing a repository (e.g. trunk). For example, if a code change listed `/atlassian/bamboo/trunk/bamboo-acceptance-test/pom.xml`, the path would be `/atlassian/bamboo/`. If you have not previously run builds with changes from your repository, you will need to ask your Fisheye administrator for the repository path indexed by Fisheye.

---

**Shared credentials**

You can store credentials within Bamboo for easier access to repositories and Amazon Web Services. The access details that you provide are available to all plans on your Bamboo server.

To manage shared credentials:

1. Click the [icon](#) in the Bamboo header and choose **Overview**.
2. Go to **Build resources > Shared credentials**.
3. You can **add**, **edit**, or **delete** existing credentials.

**Related pages:**
- Linking to source code repositories
- Checking out code
- Configuring plans

---

**Adding shared credentials**

1. Click **Add shared credentials** and select the type of credentials that you want to add
2. Provide the details:

<table>
<thead>
<tr>
<th>Type</th>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Credential name</td>
<td>The name of the credential set. Make the name meaningful, as Bamboo refers to the credential set by its name without quoting the details.</td>
</tr>
<tr>
<td>AWS</td>
<td>Access key ID</td>
<td>Credentials assigned to each IAM user in the AWS management console. For more information, see <a href="#">AWS account for Bamboo</a>.</td>
</tr>
<tr>
<td></td>
<td>Secret access key</td>
<td></td>
</tr>
<tr>
<td>SSH</td>
<td>SSH key</td>
<td>The private key from the SSH key pair that you created to authenticate with a repository. You must specify the public key on the repository host side.</td>
</tr>
<tr>
<td></td>
<td>SSH passphrase</td>
<td>The passphrase for accessing the SSH private key</td>
</tr>
<tr>
<td></td>
<td>Username and password</td>
<td>The username with which you want to authenticate</td>
</tr>
</tbody>
</table>

---

Created by Atlassian in 2018. Licensed under a [Creative Commons Attribution 2.5 Australia License](#).
3. Click **Save credentials** to add the credentials to the shared credentials list.

**Editing shared credentials**

You can modify the details of the existing shared credential by clicking **Edit** next to the credential name and selecting the **Change** check box.

**Deleting shared credentials**

You can delete existing shared credentials by clicking **Delete** next to the credential name.

After you click **Delete**, Bamboo displays a message with a list of repositories or plan tasks that depend on the credential and might break if you delete it.

**Linking to source code repositories v5.14**

A key part of setting up your continuous integration build process is to specify the code repositories that Bamboo will work with. You can specify repositories at the following levels in Bamboo:

- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level, described below.

**Important changes to Linked Repositories that affect usage and permissions**

Linked repositories are now the preferred way to define and share repository configuration between plans in Bamboo. As a result, we've made two changes that you should be aware of:

- When users create plans, they are only given the option to select from Linked Repositories. This requires that users have the Create plan global permission.
- Users will need the Create Plan global permission in order to create Linked Repositories. Note that this permission alone does not permit a user to create or edit a plan.

In the long term, Atlassian plans to deprecate the repository configuration defined against the plan. These configurations can be converted to Linked repositories by clicking **Convert to linked repository** in each plan’s repository configuration page.

**Link a source code repository for all Bamboo plans**

Linked repositories are available globally to all plans and jobs configured on the Bamboo server. Doing this can save you from having to reconfigure the source repositories in multiple places if these ever change - any changes to a linked repository are applied to every plan or job that uses that repository.

You need the 'Create plan' or 'Admin' global permission to configure linked repositories.

1. Click the 'cog' icon in the Bamboo header and then **Linked repositories**.
2. Click **Add repository**.
3. Select your repository type from the available menu options. For configuration details for a particular repository type, please refer to one of the following pages:
   - Bitbucket (for Bitbucket Cloud)
   - Stash (for Bitbucket Server)
   - Git
   - GitHub
   - Mercurial
   - Subversion
   - CVS
   - Perforce

If you need to use an unsupported type of repository, a number of third-party Source Repository plugin modules are available (e.g. the ClearCase plugin). You can also write a **Source Repository Module plugin** to enable Bamboo to connect to your repository.

Note that shared source repositories are no longer the preferred way to share repository configuration between plans. Use linked repositories instead!

**Configure a repository for a plan**

When you create a new plan, the source repository you specify becomes the default. It is used by the plan's 'Default Job' and can be used by
other jobs added to this plan.

1. Navigate to the plan. See Configuring plans for instructions.
2. Choose Actions > Configure plan.
   - Click the Repositories tab to see all the repositories that have been added to the plan.
   - Click a repository name in the list to edit its configuration details.
   - Click Add repository to configure a repository to be used by the plan.

For configuration details for a particular repository type, please refer to one of the following pages:
- Bitbucket (for Bitbucket Cloud)
- Stash (for Bitbucket Server)
- Git
- GitHub
- Mercurial
- Subversion
- CVS
- Perforce

Please note that In the long term, Atlassian plans to deprecate the repository configuration defined against a plan. These configurations can be converted to linked repositories by clicking Convert to linked repository in each plan’s repository configuration page.

Configure a repository for a job

You can specify additional repositories for a Bamboo plan to work with at the job level, perhaps for tasks in later stages of the build.

You add the Source Code Checkout task to a job to configure a particular repository for just that job. See Checking out code about configuring the Source Code Checkout task.

Linking to source code repositories v6.0

A key part of setting up your continuous integration build process is to specify the code repositories that Bamboo will work with. You can specify repositories at the following levels in Bamboo:
- **global** – repositories are available to all plans in Bamboo.
- **plan** – repositories are available to all jobs in the Bamboo plan.
- **job** – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level, described below.

**Important changes to Linked Repositories that affect usage and permissions**

Linked repositories are now the preferred way to define and share repository configuration between plans in Bamboo. As a result, we’ve made two changes that you should be aware of:

- When users create plans, they are only given the option to select from Linked Repositories. This requires that users have the Create plan global permission.
- Users will need the Create Repository global permission in order to create Linked Repositories. Note that this permission alone does not permit a user to create or edit a plan.

In the long term, Atlassian plans to deprecate the repository configuration defined against a plan. These configurations can be converted to Linked repositories by clicking Convert to linked repository in each plan’s repository configuration page.

Link a source code repository for all Bamboo plans

Linked repositories are available globally to all plans and jobs configured on the Bamboo server. Doing this can save you from having to reconfigure the source repositories in multiple places if these ever change - any changes to a linked repository are applied to every plan or job that uses that repository.

You need the ‘Create plan’ or ‘Admin’ global permission to configure linked repositories.

1. Click the ‘cog’ icon in the Bamboo header and then Linked repositories.
2. Click Add repository.
3. Select your repository type from the available menu options. For configuration details for a particular repository type, please refer to one of the following pages:
   - Bitbucket (for Bitbucket Cloud)
   - Stash (for Bitbucket Server)
   - Git
   - GitHub
   - Mercurial
   - Subversion
   - CVS
   - Perforce

If you need to use an unsupported type of repository, a number of third-party Source Repository plugin modules are available (e.g. the ClearCase plugin). You can also write a Source Repository Module plugin to enable Bamboo to connect to your repository.
Note that shared source repositories are no longer the preferred way to share repository configuration between plans. Use linked repositories instead!

Configure a repository for a plan

When you create a new plan, the source repository you specify becomes the default. It is used by the plan's 'Default Job' and can be used by other jobs added to this plan.

1. Navigate to the plan. See Configuring plans for instructions.
2. Choose Actions > Configure plan.
   - Click the Repositories tab to see all the repositories that have been added to the plan.
   - Click a repository name in the list to edit its configuration details.
   - Click Add repository to configure a repository to be used by the plan.
     For configuration details for a particular repository type, please refer to one of the following pages:
     - Bitbucket (for Bitbucket Cloud)
     - Stash (for Bitbucket Server)
     - Git
     - GitHub
     - Mercurial
     - Subversion
     - CVS
     - Perforce

Please note that In the long term, Atlassian plans to deprecate the repository configuration defined against a plan. These configurations can be converted to linked repositories by clicking Convert to linked repository in each plan's repository configuration page.

Configure a repository for a job

You can specify additional repositories for a Bamboo plan to work with at the job level, perhaps for tasks in later stages of the build.

You add the Source Code Checkout task to a job to configure a particular repository for just that job. See Checking out code for details about configuring the Source Code Checkout task.

Smart Mirroring

Starting with version 6.2 Bamboo provides support for Bitbucket Server Smart Mirroring functionality. Smart Mirroring allows you to use local repositories for storing your repository data to avoid having to wait when cloning a repository from a remote location.

For detailed information on Smart Mirroring, see the Bitbucket Server documentation.

<table>
<thead>
<tr>
<th>Prerequisites</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bitbucket Server 5.0.0 or later</td>
</tr>
<tr>
<td>Bitbucket Server Data Center license with mirrors support</td>
</tr>
<tr>
<td>routing from Bamboo to Bitbucket Server instance</td>
</tr>
<tr>
<td>routing between agent and mirror enabled</td>
</tr>
</tbody>
</table>

To enable Smart Mirroring in Bamboo:

1. Go to
   > Overview > Linked repositories.
2. Select your Bitbucket Server repository.
3. In the Edit repository section, select Advanced options.
4. From the Mirror drop-down list, select your mirror location.
Smart Mirroring v6.2
Starting with version 6.2 Bamboo provides support for Bitbucket Server Smart Mirroring functionality. Smart Mirroring allows you to use local repositories for storing your repository data to avoid having to wait when cloning a repository from a remote location.

For detailed information on Smart Mirroring, see the Bitbucket Server documentation.

Prerequisites

- Bitbucket Server 5.0.0 or later
- Bitbucket Server Data Center license with mirrors support
- routing from Bamboo to Bitbucket Server instance
- routing between agent and mirror enabled

To enable Smart Mirroring in Bamboo:

1. Go to
   > Overview > Linked repositories.
2. Select your Bitbucket Server repository.
3. In the Edit repository section, select Advanced options.
4. From the Mirror drop-down list, select your mirror location.

Downgrading from Bitbucket Server Data Center license to a regular license may cause problems. In the unlikely event of such a downgrade, we recommend to switch all repositories to primary before switching versions.

Downgrading from Bitbucket Server Data Center from version 5+ to version 4 may cause problems. In the unlikely event of such a downgrade, we recommend to switch all repositories to primary before switching versions.
Enabling webhooks

Webhooks allow your repositories other than Bitbucket Server to communicate with Bamboo. Once you set up a webhook for a repository, a repository sends the HTTP request to Bamboo with every new commit. This HTTP request, in turn, triggers Bamboo Specs scan repository to see if there are any changes to Specs. If Bamboo detects any changes in a repository, it automatically updates necessary plans and deployments.

Bamboo supports the use of Java and YAML Specs with the following repositories:

- Bitbucket Cloud
- Git
- GitHub
- Subversion

To enable webhooks in your repository:

1. In Bamboo, generate a URL used as a destination for your webhook:
   a. In the top navigation bar, click Create > Create Bamboo Specs.
   b. Select your project type.
   c. Select the repository for Bamboo Specs.
   d. Copy the URL that is generated for you as the destination for the webhook.

2. In the repository you want to use for storing Bamboo Specs, use the Bamboo URL to enable the webhook:
   a. Go to your repository settings.
   b. Find webhook-specific configuration.
   c. Paste in the URL Bamboo provided you with.

Bamboo webhook is now enabled in your repository.

Triggering builds

Triggering in Bamboo allows plan builds to be started automatically. Bamboo has the following trigger methods:

- Trigger a build if code has changed:
  - Poll the repository for changes
  - A push to the repository triggers the build

- Trigger a build based on a schedule:
  - Cron-based scheduling
  - Single daily build

- Trigger a build depending on the outcome of other plans:
  - Plan builds are triggered by preceding successful builds of other plans.
  - Plan only builds if other specified plans are building successfully.

Downgrading from Bitbucket Server Data Center license to a regular license may cause problems. In the unlikely event of such a downgrade, we recommend to switch all repositories to primary before switching versions.

Downgrading from Bitbucket Server Data Center from version 5+ to version 4 may cause problems. In the unlikely event of such a downgrade, we recommend to switch all repositories to primary before switching versions.
Note that a plan that has no configured triggers can only be started manually, or if it is dependent on the successful build of another plan.

From Bamboo 4.3, you can configure multiple triggers for each plan. This allows a plan to be triggered by different trigger types, and to have triggering scenarios such as "every 5 minutes between 9:00am and 10:00am, and every 20 minutes between 1:00pm and 10:00pm".

Triggers can only be configured by a Bamboo administrator.

Choosing a triggering strategy

This table lists the ways in which plan builds can be triggered in Bamboo.

<table>
<thead>
<tr>
<th>Triggering option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Polling the repository for changes</td>
<td>Bamboo will 'poll' the selected source code repositories for code changes, using either a specified interval (that is, periodically) or a schedule. If Bamboo detects code changes, a build of the plan is triggered.</td>
</tr>
<tr>
<td></td>
<td>• Your VCS must service a 'check out' or 'update' command whenever it is polled, even if no code has changed in a repository.</td>
</tr>
<tr>
<td></td>
<td>See Polling the repository for changes.</td>
</tr>
<tr>
<td>Repository triggers the build when changes are committed</td>
<td>Bamboo waits to receive a message about changed code from any of the selected source code repositories. When Bamboo receives such a message, a build of the plan is triggered.</td>
</tr>
<tr>
<td></td>
<td>• This option minimizes server load, because message events are sent only when code changes to a repository are committed.</td>
</tr>
<tr>
<td></td>
<td>• You must configure your source code management system to send message events to Bamboo about code changes in the repositories.</td>
</tr>
<tr>
<td></td>
<td>• This is the default option when you use a linked Bitbucket Server repository.</td>
</tr>
<tr>
<td></td>
<td>See Repository triggers the build when changes are committed.</td>
</tr>
<tr>
<td>Cron-based scheduling</td>
<td>Bamboo will trigger scheduled builds of this plan based on a cron expression.</td>
</tr>
<tr>
<td></td>
<td>• This option allows you to schedule builds when server load is likely to be minimal, for example, outside office hours.</td>
</tr>
<tr>
<td></td>
<td>• Scheduled builds are triggered irrespective of any code changes in the source code repositories.</td>
</tr>
<tr>
<td></td>
<td>See Cron-based scheduling.</td>
</tr>
<tr>
<td>Single daily build</td>
<td>Bamboo will trigger a build of the plan once per day at a specified time.</td>
</tr>
<tr>
<td></td>
<td>• Can be set up to run at a time of your choice.</td>
</tr>
<tr>
<td></td>
<td>• This option is suitable if a build of this plan takes a long time to complete.</td>
</tr>
<tr>
<td></td>
<td>• Scheduled builds are triggered irrespective of any code changes in the source code repositories.</td>
</tr>
<tr>
<td></td>
<td>See Single daily build.</td>
</tr>
</tbody>
</table>
Conditional build triggers

This feature is only available when configuring an existing plan.

You can choose to run builds of this plan only if other specified plans are currently passing. Those plans must build successfully before this plan will be built. See also Setting up plan build dependencies.

Note that, because a plan may have multiple triggers configured, each of which can have differing trigger conditions, it is possible for the plan build to be started by one trigger, even though another trigger is currently blocked.

To specify build trigger conditions:

1. Choose Build > All build plans from the Bamboo header.
2. Locate the plan in the list and click the edit icon ( ) to display the plan’s configuration pages.
3. Click the Triggers tab, and click either an existing trigger or Add trigger.
4. Select Only run Build if other Plans are currently passing, under ‘Trigger conditions’.
5. Specify one or more other plans by adding their full keys.

Trigger conditions

Only run Build if other Plans are currently passing

Plan Keys

Enter comma separated Plan Keys.

Polling the repository for changes

You can configure Bamboo to poll the repository for source code changes, either:

- periodically (e.g. every 180 seconds), or
- based on a schedule (e.g. the second Sunday of every month at 5:00 am).

If Bamboo detects a change in the source code, a build of your plan is triggered.

Related pages:

- Triggering builds
- Repository triggers the build when changes are committed
- Cron-based scheduling
- Single daily build

To configure Bamboo to poll the repository for source code changes:

1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon ( ) to display the plan’s configuration pages.
3. Click the Triggers tab, then click either an existing trigger or Add Trigger.
4. Optionally, enter a trigger description.
5. Choose Trigger type > Polling the Repository for changes.
6. Bamboo displays the available repositories for the plan, as previously configured on the Source Repositories tab. Choose the repositories that this trigger should apply to.
7. Choose a polling strategy:
   a. Periodically
      Enter a Polling Frequency value (in seconds) for the time between when Bamboo checks for repository changes.
   b. Scheduled
      Click the edit icon ( ) to use the Schedule Editor to set the polling schedule.
      Note, this is a schedule for polling your repository: a plan build will only be triggered if there are source code changes. See Triggering builds.
      Note that for the Cron Expression option, a cron expression consists of 6 mandatory and one optional field. The fields in sequential order are: seconds, minutes, hours, day-of-month, month, day-of-week and (optional) year. For example, 0 0 1 * 1 #2. For information on Cron expressions, see this FAQ: Constructing a cron expression in Bamboo.
8. Click Save Trigger.
Polling the repository for changes v5.14

You can configure Bamboo to poll the repository for source code changes, either:

- periodically (e.g. every 180 seconds), or
- based on a schedule (e.g. the second Sunday of every month at 5:00 am).

If Bamboo detects a change in the source code, a build of your plan is triggered.

Related pages:
- Triggering builds
- Repository triggers the build when changes are committed
- Cron-based scheduling
- Single daily build

To configure Bamboo to poll the repository for source code changes:

1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon to display the plan's configuration pages.
3. Click the Triggers tab, then click either an existing trigger or Add Trigger.
4. Optionally, enter a trigger description.
5. Choose Trigger type > Polling the Repository for changes.
6. Bamboo displays the available repositories for the plan, as previously configured on the Source Repositories tab. Choose the repositories that this trigger should apply to.
7. Choose a polling strategy:

<table>
<thead>
<tr>
<th>Periodically</th>
<th>Enter a Polling Frequency value (in seconds) for the time between when Bamboo checks for repository changes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scheduled</td>
<td>Click the edit icon ( ) to use the Schedule Editor to set the polling schedule. Note, this is a schedule for polling your repository: a plan build will only be triggered if there are source code changes. See Triggering builds. Note that for the Cron Expression option, a cron expression consists of 6 mandatory and one optional field. The fields in sequential order are: seconds, minutes, hours, day-of-month, month, day-of-week and (optional) year. For example, 0 0 1 * * 2. For information on Cron expressions, see this FAQ: Constructing a cron expression in Bamboo</td>
</tr>
</tbody>
</table>

8. Click Save Trigger.

Polling the repository for changes v6.1

You can configure Bamboo to poll the repository for source code changes, either:
To configure Bamboo to poll the repository for source code changes:

1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon to display the plan's configuration pages.
3. Click the Triggers tab, then click either an existing trigger or Add Trigger.
4. Optionally, enter a trigger description.
5. Choose Trigger type > Polling the Repository for changes.
6. Bamboo displays the available repositories for the plan, as previously configured on the Source Repositories tab. Choose the repositories that this trigger should apply to.
7. Choose a polling strategy:
   a. Periodically
      Enter a Polling Frequency value (in seconds) for the time between when Bamboo checks for repository changes.
   b. Scheduled
      Click the edit icon ( ) to use the Schedule Editor to set the polling schedule.
      Note, this is a schedule for polling your repository: a plan build will only be triggered if there are source code changes. See Triggering builds.
      Note that for the Cron Expression option, a cron expression consists of 6 mandatory and one optional field. The fields in sequential order are: seconds, minutes, hours, day-of-month, month, day-of-week and (optional) year. For example, 0 0 1 ? * 1#2. For information on Cron expressions, see this FAQ: Constructing a cron expression in Bamboo.
8. Click Save Trigger.

Repository triggers the build when changes are committed

Using the source repository to trigger the build of a plan is one of the available methods for triggering builds in Bamboo.

“Repository triggers the build when changes are committed” has the advantage of placing minimal load on your Bamboo server. However, it requires that your source repository is configured to fire an event to the Bamboo server (which the configured Plan will 'listen for').

Configuring the repository to trigger the build when changes are committed requires two changes:
1. Configuring your source repository
2. Configuring Bamboo to respond to post-commit messages

The overall process is: a commit to the repository causes a post-commit message to be sent to Bamboo. Bamboo responds by checking the repository for unbuilt changes. If changes are found, Bamboo triggers a build.

1. Configuring your source repository

Configure your source code management system's repository to send post-commit event messages to Bamboo. These messages tell Bamboo to begin building the plans that use this repository.

For Bitbucket Cloud, click here to expand...

Add the Bamboo Webhook to your repository in Bitbucket Cloud. No further action is necessary on your local repository. Each push of new commits in to Bitbucket will trigger the build based on your configuration.

For Bitbucket Server, click here to expand...

When you create a plan that uses a linked Bitbucket Server repository, Bamboo uses the 'Bitbucket repository triggers the build when changes are committed' trigger option by default.
### For Git, click here to expand...

Edit the Git repository's `.git/hooks/post-receive` trigger file, for example with the following:

```bash
/path/to/postCommitBuildTrigger.sh http://bambooserver
JIRA-MAIN JIRA-BRANCH
```

where:
- Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
- Jira is the project key
- BRANCH or MAIN are the plan key

For Git, use the SVN `postCommitBuildTrigger.sh` script. See below for more information about the scripts.

### For Mercurial, click here to expand...

Edit the Hg repository's `.hg/hgrc` settings, for example with the following:

```ini
[hooks]
changegroup.update = /path/to/postCommitBuildTrigger.sh
http://bambooserver JIRA-MAIN JIRA-BRANCH
```

where:
- Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
- Jira is the project key
- BRANCH or MAIN are the plan key

See below for more information about the scripts.

### For Subversion, click here to expand...

If you are using a remote SVN server, copy file 
"atlassian-bamboo/repositoryScripts/svn-triggers/postCommitBuildTrigger.sh" (.py for Windows installations) located in the Bamboo install directory to the SVN repository `.../hook/post-commit` folder so that the `postCommitBuildTrigger` file is accessible from the `post-commit` trigger file.

Edit the Subversion repository's `.hacks/post-commit` trigger file, for example with the following:

```bash
/path/to/postCommitBuildTrigger.sh http://bambooserver
JIRA-MAIN JIRA-BRANCH
```

where:
- Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
- Jira is the project key
- BRANCH or MAIN are the plan key

See below for more information about the scripts. Also, refer to Configuring source code management triggers for Subversion.

### For Perforce, click here to expand...

Add the script as a change-commit trigger.

```
triggerName change-commit //myDepot/...
"/usr/local/bin/postCommitBuildTrigger.sh
http://bambooserver/ MYPLAN-DEFAULT"
```

See below for more information about the scripts.

### For CVS, click here to expand...
Edit two files in the CVSROOT module: `commitinfo` and `loginfo`.

- For `commitinfo`, add a line like this:

  ```
  ^jira(/|$) /path/to/preCommit.sh
  ```

  where "jira" is your module.
- For `loginfo`, you can add a line, for example the following:

  ```
  ^jira(/|$) /path/to/postCommitBuildTrigger.sh %{}
  http://bambooserver JIRA-MAIN JIRA-BRANCH
  ```

  where:
  - Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
  - Jira is the project key
  - BRANCH or MAIN are the plan key

  See below for more information about the scripts. Please refer to Configuring source code management triggers for Subversion.

- You can download the scripts using this link. Use the same SVN script for Git. Copy the scripts to your repository. The scripts can also be found in the `scripts` folder of your Bamboo Installation Directory.
- Depending on which operating system your repository is running on, you may need to edit the scripts. The scripts assume that `wget` is in `/usr/bin/`; if this isn't the case for your repository (e.g. Solaris 10 has it in `/usr/sfw/bin/`), edit the scripts and change `/usr/bin/` to the appropriate location.
- Ensure that the user which Bamboo is running as has appropriate file permissions to execute the scripts, i.e. the scripts should be executable by non-root user(s).

2. Configuring Bamboo to respond to post-commit messages

Before you begin:

- Triggering a build when there is no repository update — Bamboo will ignore build triggers if the local working copy and the repository copy have the same revision numbers. When testing your build triggers, ensure that the local working copy is not the latest version - if this is the case, Bamboo will take no further action.
- If you're using the Bitbucket Cloud Bamboo post-push hook, ensure that the user you are using to authenticate triggering the build has the 'build' permission on the plan you are attempting to trigger.

To configure Bamboo to trigger a build on code check in:

1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon to display the plan's configuration pages.
3. Click the Triggers tab, then Add Trigger.
5. Optionally, enter a trigger description.
6. Bamboo displays the available repositories for the plan, as previously configured on the Source Repositories tab. Choose the repositories that this trigger should apply to.
7. Only enter an IP address in Trigger IP Addresses if you want Bamboo to trigger on post-commit messages from other than the primary IP address for the repository.

If you use a Mercurial or Git repository then you must type the IP address of your repository host in Trigger IP Addresses. For Bitbucket Cloud the current outbound IP addresses can be found at Access Bitbucket Cloud from Behind a Firewall.

8. Click Save Trigger.

For Subversion, click here to expand...

If you are using a remote SVN server, copy file
"atlassian-bamboo/repositoryScripts/svn-triggers/postCommitBuildTrigger.sh" (.py for Windows installations) located in the Bamboo install directory to the SVN repository .../hook/post-commit folder so that the `postCommitBuildTrigger` file is accessible from the `post-commit` trigger file.

Edit the Subversion repository's `hooks/post-commit` trigger file, for example with the following:

```
/path/to/postCommitBuildTrigger.sh http://bambooserver
JIRA-MAIN JIRA-BRANCH
```

where:
- Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
- Jira is the project key
- BRANCH or MAIN are the plan key

See below for more information about the scripts. Also, refer to Configuring source code management triggers for Subversion.

For Perforce, click here to expand...

Add the script as a change-commit trigger.

```
triggerName change-commit //myDepot/...
"/usr/local/bin/postCommitBuildTrigger.sh
http://bambooserver/ MYPLAN-DEFAULT"
```

See below for more information about the scripts.

For CVS, click here to expand...
Edit two files in the CVROOT module: `commitinfo` and `loginfo`.

- For `commitinfo`, add a line like this:

```
^jira(/|$) /path/to/preCommit.sh
```

where "jira" is your module.
- For `loginfo`, you can add a line, for example the following:

```
^jira(/|$) /path/to/postCommitBuildTrigger.sh %{
http://bambooserver JIRA-MAIN JIRA-BRANCH
```

where:
- Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
- Jira is the project key
- BRANCH or MAIN are the plan key

See below for more information about the scripts. Please refer to Configuring source code management triggers for Subversion.

- You can download the scripts using this link. Use the same SVN script for Git. Copy the scripts to your repository. The scripts can also be found in the `/scripts` folder of your Bamboo Installation Directory.
- Depending on which operating system your repository is running on, you may need to edit the scripts. The scripts assume that `wget` is in `/usr/bin/`; if this isn't the case for your repository (e.g. Solaris 10 has `wget` in `/usr/sfw/bin/`), edit the scripts and change `/usr/bin/` to the appropriate location.
- Ensure that the user which Bamboo is running as has appropriate file permissions to execute the scripts, i.e. the scripts should be executable by non-root user(s).

2. Configuring Bamboo to respond to post-commit messages

Before you begin:

- Triggering a build when there is no repository update — Bamboo will ignore build triggers if the local working copy and the repository copy have the same revision numbers. When testing your build triggers, ensure that the local working copy is not the latest version - if this is the case, Bamboo will take no further action.
- If you're using the Bitbucket Cloud Bamboo post-push hook, ensure that the user you are using to authenticate triggering the build has the 'build' permission on the plan you are attempting to trigger.

To configure Bamboo to trigger a build on code check in:

1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon to display the plan's configuration pages.
3. Click the Triggers tab, then Add Trigger.
5. Optionally, enter a trigger description.
6. Bamboo displays the available repositories for the plan, as previously configured on the Source Repositories tab. Choose the repositories that this trigger should apply to.
7. If you use a Mercurial or Git repository then you must type the IP address of your repository host in Trigger IP Addresses. For Bitbucket Cloud outbound IP addresses can be found at Access Bitbucket Cloud from Behind a Firewall.
8. Click Save Trigger.

Screenshot: Build Strategy – repository triggers the build when changes are committed
Repository triggers the build when changes are committed v6.3

Using the source repository to trigger the build of a plan is one of the available methods for triggering builds in Bamboo.

"Repository triggers the build when changes are committed" has the advantage of placing minimal load on your Bamboo server. However, it requires that your source repository is configured to fire an event to the Bamboo server (which the configured Plan will 'listen for').

Configuring the repository to trigger the build when changes are committed requires two changes:

1. Configuring your source repository
2. Configuring Bamboo to respond to post-commit messages

The overall process is: a commit to the repository causes a post-commit message to be sent to Bamboo. Bamboo responds by checking the repository for unbuilt changes. If changes are found, Bamboo triggers a build.

For Subversion, click here to expand...

If you are using a remote SVN server, copy file
"atlassian-bamboo/repositoryScripts/svn-triggers/postCommitBuildTrigger.sh" (.py for Windows installations) located in the Bamboo install directory to the SVN repository `.../hook/post-commit` folder so that the `postCommitBuildTrigger` file is accessible from the `post-commit` trigger file.

Edit the Subversion repository's `hooks/post-commit` trigger file, for example with the following:

```
/path/to/postCommitBuildTrigger.sh http://bambooserver
JIRA-MAIN JIRA-BRANCH
```

where:
- Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
- Jira is the project key
- BRANCH or MAIN are the plan key

See below for more information about the scripts. Also, refer to Configuring source code management triggers for Subversion.

For Perforce, click here to expand...

Add the script as a change-commit trigger.

```
triggerName change-commit //myDepot/...
"/usr/local/bin/postCommitBuildTrigger.sh
http://bambooserver/ MYPLAN-DEFAULT"
```

See below for more information about the scripts.

For CVS, click here to expand...
Edit two files in the CVSROOT module: `commitinfo` and `logininfo`.

- For `commitinfo`, add a line like this:

```
^jira(/|$) /path/to/preCommit.sh
```

where "jira" is your module.

- For `logininfo`, you can add a line, for example the following:

```
^jira(/|$) /path/to/postCommitBuildTrigger.sh {}
http://bambooserver JIRA-MAIN JIRA-BRANCH
```

where:
- Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
- Jira is the project key
- BRANCH or MAIN are the plan key

See below for more information about the scripts. Please refer to Configuring source code management triggers for Subversion.

You can download the scripts using this [link](#). Use the same SVN script for Git. Copy the scripts to your repository. The scripts can also been found in the `/scripts` folder of your Bamboo Installation Directory.

Depending on which operating system your repository is running on, you may need to edit the scripts. The scripts assume that `wget` is in `/usr/bin/`; if this isn't the case for your repository (e.g. Solaris 10 has it in `/usr/sfw/bin/`), edit the scripts and change `/usr/bin/` to the appropriate location.

Ensure that the user which Bamboo is running as has appropriate file permissions to execute the scripts, i.e. the scripts should be executable by non-root user(s).

### 2. Configuring Bamboo to respond to post-commit messages

Before you begin:

- Triggering a build when there is no repository update — Bamboo will ignore build triggers if the local working copy and the repository copy have the same revision numbers. When testing your build triggers, ensure that the local working copy is not the latest version - if this is the case, Bamboo will take no further action.
- If you're using the [Bitbucket Cloud Bamboo post-push hook](#), ensure that the user you are using to authenticate triggering the build has the 'build' permission on the plan you are attempting to trigger.

**To configure Bamboo to trigger a build on code check in:**

1. Click [Dashboard](#) and then the [All Plans](#) tab.
2. Locate the plan in the list and click the edit icon to display the plan's configuration pages.
3. Click the [Triggers](#) tab, then [Add Trigger](#).
4. Choose [Trigger type](#) > [Remote Trigger](#).
5. Optionally, enter a trigger description.
6. Bamboo displays the available repositories for the plan, as previously configured on the [Source Repositories](#) tab. Choose the repositories that this trigger should apply to.
7. Only enter an IP address in [Trigger IP Addresses](#) if you want Bamboo to trigger on post-commit messages from other than the primary IP address for the repository.

If you use a Mercurial or Git repository then you must type the IP address of your repository host in **Trigger IP Addresses**.

For Bitbucket Cloud [outbound](#) IP addresses can be found at [Access Bitbucket Cloud from Behind a Firewall](#)

8. Click [Save Trigger](#).

**Screenshot: Build Strategy – repository triggers the build when changes are committed**
Repository triggers the build when changes are committed v6.4

Using the source repository to trigger the build of a plan is one of the available methods for triggering builds in Bamboo.

"Repository triggers the build when changes are committed" has the advantage of placing minimal load on your Bamboo server. However, it requires that your source repository is configured to fire an event to the Bamboo server (which the configured Plan will 'listen for').

Configuring the repository to trigger the build when changes are committed requires two changes:
1. Configuring your source repository
2. Configuring Bamboo to respond to post-commit messages

The overall process is: a commit to the repository causes a post-commit message to be sent to Bamboo. Bamboo responds by checking the repository for unbuilt changes. If changes are found, Bamboo triggers a build.

Related pages:
- Triggering builds
- Polling the repository for changes
- Cron-based scheduling
- Single daily build

1. Configuring your source repository

Configure your source code management system's repository to send post-commit event messages to Bamboo. These messages tell Bamboo to begin building the plans that use this repository.

For Bitbucket Cloud, click here to expand...

Add the Bamboo Webhook to your repository in Bitbucket Cloud. No further action is necessary on your local repository. Each push of new commits into Bitbucket will trigger the build based on your configuration.

For Bitbucket Server, click here to expand...

When you create a plan that uses a linked Bitbucket Server repository, Bamboo uses the 'Bitbucket repository triggers the build when changes are committed' trigger option by default.

For Git, click here to expand...
Edit the Git repository's `.git/hooks/post-receive` trigger file, for example with the following:

```
/path/to/postCommitBuildTrigger.sh http://bambooserver
JIRA-MAIN JIRA-BRANCH
```

where:
- Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
- Jira is the project key
- BRANCH or MAIN are the plan key

For Git, use the SVN `postCommitBuildTrigger.sh` script. See below for more information about the scripts.

For Mercurial, click here to expand...

Edit the Hg repository's `.hg/hgrc` settings, for example with the following:

```
[hooks]
changepool.update = /path/to/postCommitBuildTrigger.sh
http://bambooserver JIRA-MAIN JIRA-BRANCH
```

where:
- Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
- Jira is the project key
- BRANCH or MAIN are the plan key

See below for more information about the scripts.

For Subversion, click here to expand...

If you are using a remote SVN server, copy file
"atlassian-bamboo/repositoryScripts/svn-triggers/postCommitBuildTrigger.sh" (.py for Windows installations) located in the Bamboo install directory to the SVN repository `.../hook/post-commit` folder so that the `postCommitBuildTrigger` file is accessible from the `post-commit` trigger file.

Edit the Subversion repository's `.hooks/post-commit` trigger file, for example with the following:

```
/path/to/postCommitBuildTrigger.sh http://bambooserver
JIRA-MAIN JIRA-BRANCH
```

where:
- Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
- Jira is the project key
- BRANCH or MAIN are the plan key

See below for more information about the scripts. Also, refer to Configuring source code management triggers for Subversion.

For Perforce, click here to expand...

Add the script as a change-commit trigger.
```
triggerName change-commit //myDepot/...
"/usr/local/bin/postCommitBuildTrigger.sh
http://bambooServer/ MYPLAN-DEFAULT"
```

See below for more information about the scripts.

For CVS, click here to expand...
Edit two files in the CVSROOT module: `commitinfo` and `logininfo`.

- For `commitinfo`, add a line like this:

  ```
  ^jira(/|$) /path/to/preCommit.sh
  ```

  where "jira" is your module.

- For `logininfo`, you can add a line, for example the following:

  ```
  ^jira(/|$) /path/to/postCommitBuildTrigger.sh %{}
  http://bambooserver JIRA-MAIN JIRA-BRANCH
  ```

  where:
  - Jira-MAIN and Jira-BRANCH are the Bamboo plans that you would like to trigger
  - Jira is the project key
  - BRANCH or MAIN are the plan key

  See below for more information about the scripts. Please refer to Configuring source code management triggers for Subversion.

- You can download the scripts using this link. Use the same SVN script for Git. Copy the scripts to your repository. The scripts can also been found in the `/scripts` folder of your Bamboo Installation Directory.
- Depending on which operating system your repository is running on, you may need to edit the scripts. The scripts assume that `/usr/bin/` is in `/usr/bin/`: if this isn't the case for your repository (e.g. Solaris 10 has it in `/usr/sfw/bin/`), edit the scripts and change `/usr/bin/` to the appropriate location.
- Ensure that the user which Bamboo is running as has appropriate file permissions to execute the scripts, i.e. the scripts should be executable by non-root user(s).

### 2. Configuring Bamboo to respond to post-commit messages

Before you begin:

- Triggering a build when there is no repository update — Bamboo will ignore build triggers if the local working copy and the repository copy have the same revision numbers. When testing your build triggers, ensure that the local working copy is not the latest version - if this is the case, Bamboo will take no further action.
- If you're using the Bitbucket Cloud Bamboo post-push hook, ensure that the user you are using to authenticate triggering the build has the "build" permission on the plan you are attempting to trigger.

To configure Bamboo to trigger a build on code check in:

1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon to display the plan's configuration pages.
3. Click the Triggers tab, then Add Trigger.
5. Optionally, enter a trigger description.
6. Bamboo displays the available repositories for the plan, as previously configured on the Source Repositories tab. Choose the repositories that this trigger should apply to.
7. Only enter an IP address in Trigger IP Addresses if you want Bamboo to trigger on post-commit messages from other than the primary IP address for the repository.

If you use a Mercurial or Git repository then you must type the IP address of your repository host in Trigger IP Addresses. For Bitbucket Cloud outbound IP addresses can be found at Access Bitbucket Cloud from Behind a Firewall.

8. Click Save Trigger.

Screenshot: Build Strategy – repository triggers the build when changes are committed
Cron-based scheduling

Using a cron-based schedule to trigger the build of a plan is one of the available methods for triggering builds in Bamboo. This schedule is configured using the Schedule Editor.

The schedule can be daily (times per day), weekly (days per week), monthly (days per month) or based on a cron expression.

To schedule a plan build using a cron expression:

1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon ( 
3. ) to display the plan's configuration pages.
4. Click the Triggers tab, then click either an existing trigger or Add Trigger.
5. Optionally, enter a trigger description.
6. Choose Trigger type > Cron Based Scheduling.
7. Click the edit icon ( 
8. ) next to the current schedule to display the Schedule Editor.
9. Use the Schedule Editor (see screenshots below), to specify the build schedule for your plan. For information about cron expressions, see this FAQ: Constructing a cron expression in Bamboo.
10. Click Save Trigger.

Screenshots: Schedule Editor options
Constructing a cron expression in Bamboo

Cron is a time-based job scheduler used in Unix/Linux computer operating systems with a unique and powerful terminology. A number of scheduling features in Bamboo, such as build expiry and elastic instance scheduling, require you to specify your requirements as a cron-based expression. For example, a cron expression such as "0 0/30 9-19 ? * MON-FRI" signifies that a scheduled event will be triggered every half an hour from 9am to 7pm, Monday to Friday.

A cron expression comprises of 6 mandatory and one optional field to specify a schedule. The fields in sequential order are: seconds, minutes, hours, day-of-month, month, day-of-week and (optional) year, i.e.

<seconds> <minutes> <hours> <day-of-month> <month> <day-of-week> <year (optional)>

Each field can be expressed as an integer (e.g. 1, 2, 3, etc) and special characters can be used in most fields as well (i.e. ', -, *, ?, L, W, #').

Bamboo uses OpenSymphony’s Quartz to schedule cron tasks. The syntax it accepts may vary from other cron implementations. Please refer to the Quartz CronTrigger Tutorial documentation for further information on each of these parameters and more detailed examples.

Single daily build

Triggering the build of a plan to run at a particular time each day is one of the available methods for triggering builds in Bamboo. A "Single daily build" runs at a time of your choice. This is particularly suitable for builds that take a long time to complete.

To schedule a plan build at a specified time each day:

1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon to display the plan’s configuration pages.
3. Click the Triggers tab, then click either an existing trigger or Add Trigger.
4. Optionally, enter a trigger description.
5. Choose Trigger type > Single daily build.
6. Specify the time of day at which the build should run in Build Time. Use hh:mm format, with a 24-hour clock.
7. Click Save Trigger.

Running a plan build manually

Typically in Bamboo, your build plans are configured to be automatically triggered when code changes are committed to the working repository, or according to a schedule.

However, there can be scenarios where you do not want the plan to be automatically triggered:

- The plan should only ever be run manually.
- You want to choose the revision of the default repository that should be used for the build.
- You want to run a customized build, so as to override global variables or plan variables.
- You want to select particular manual stages to run.
- You want the plan to be triggered by other plans that build successfully first.

This page describes how to run a plan build manually, and the options available when running a customized plan build.
To start a plan build manually:

1. Locate the relevant plan on the Dashboard.
2. Click the Run icon for the plan.

Alternatively, if you are viewing the plan, simply click the Run menu.

Running a customized manual build

If you trigger a plan build manually, you can customize the following aspects of how the plan is run (when these are available):

- Choose the revision of the default repository that should be used.
- Override any global variables or plan variables with your own parameters when triggering a build manually. This is referred to as running a 'parameterized plan build'.
- Select which manual stages to run, if manual stages have been configured for the plan.

To run a customized plan build:

1. Locate the relevant plan on the Dashboard.
2. Click the plan name to go to the Plan Summary.
3. Choose Run > Run Customized.
4. Customize the following aspects of the plan:

<table>
<thead>
<tr>
<th>Revision</th>
<th>Choose a repository revision to use for the build.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note that:</td>
<td>You can only choose revisions from the default repository.</td>
</tr>
<tr>
<td></td>
<td>The build is not included in plan statistics or telemetry.</td>
</tr>
<tr>
<td></td>
<td>SVN repositories use the revision number.</td>
</tr>
<tr>
<td></td>
<td>Perforce projects use the changelist number.</td>
</tr>
<tr>
<td></td>
<td>Git repositories use the changeset number.</td>
</tr>
<tr>
<td></td>
<td>Mercurial repositories use the tag.</td>
</tr>
</tbody>
</table>

Note for Subversion repositories that make use of externals

When running a build with a custom revision on a Subversion repository with externals, Bamboo will choose the latest revision in the external repository. This is because Subversion externals always use the latest version and cannot be fixed at a specific revision.

<table>
<thead>
<tr>
<th>Build Variables</th>
<th>Click Override a variable to choose another variable to override.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stages</td>
<td>Choose the stages that should be run.</td>
</tr>
</tbody>
</table>

5. Click Run.
Rerunning a failed stage

If a stage has failed in your build, you can choose to rerun the stage (with exactly the same data) instead of the entire plan.

To rerun a stage:

1. Navigate to the failed build result, as described on Viewing a build result.
2. Choose Run > Rerun all failed Jobs to run the stage again.

Note that:

- Only failing jobs will be re-run.
- Subsequent stages will be executed automatically, unless they are manual stages.
- You might want to add a comment to the build result to record the reason for failure. The existing build result will be overwritten (Bamboo will not create a new build) and the previous failure reason will not be retained.
- For plans based on a Subversion repository, you can only rerun the failed job or the whole plan.

Related pages:
- Running a plan build manually

- Using stages in a plan

Screenshot: Rerunning a failed stage

.Rerunning a failed stage v5.14

If a stage has failed in your build, you can choose to rerun the stage (with exactly the same data) instead of the entire plan.

To rerun a stage:

1. Navigate to the failed build result, as described on Viewing a build result.
2. Choose Run > Rerun all failed Jobs to run the stage again.

Note that:

- Only failing jobs will be re-run.
- Subsequent stages will be executed automatically, unless they are manual stages.
- You might want to add a comment to the build result to record the reason for failure. The existing build result will be overwritten (Bamboo will not create a new build) and the previous failure reason will not be retained.
- For plans based on a Subversion repository, you can only rerun the failed job or the whole plan.
If a stage has failed in your build, you can choose to rerun the stage (with exactly the same data) instead of the entire plan.

**To rerun a stage:**

1. Navigate to the failed build result, as described on Viewing a build result.
2. Choose Run > Rerun all failed Jobs to run the stage again.

Note that:

- Only failing jobs will be re-run.
- Subsequent stages will be executed automatically, unless they are manual stages.
- You might want to add a comment to the build result to record the reason for failure. The existing build result will be overwritten (Bamboo will not create a new build) and the previous failure reason will not be retained.
- For plans based on a Subversion repository, you can only rerun the failed job or the whole plan.

### Triggering a Bamboo build from Bitbucket Cloud using Webhooks

Webhooks provide a way to configure Bitbucket Cloud to make requests to your server (or another external service) whenever certain events occur in Bitbucket Cloud. The purpose of this guide is to help you set up a Webhook that will trigger a Bamboo build from Bitbucket Cloud after a certain event. For example, you may want Bitbucket Cloud to trigger a Bamboo build when your repository receives a commit (aka post-commit trigger).

**Procedure**

1. First configure the Bamboo plan to trigger with a Remote trigger: Bamboo > Plan Configuration > Triggers > Add trigger > Remote trigger.
2. Bamboo requires you to whitelist the IP addresses of the source of the request to trigger under the Trigger IP Addresses field (comma separated for each IP).
   a. The current list of Bitbucket Cloud IP addresses for outbound POST requests by Webhooks: Bitbucket Cloud IP Addresses
   b. CIDR Notation is only supported in Bamboo 5.14+
   c. Bamboo’s IP whitelist also inspects the X-Forwarded-For HTTP header to determine the origin of the request. If you have a
reverse proxy forwarding requests to your Bamboo instance, depending on its configuration, you may also need to whitelist the IP address of the Proxy Server.

3. Add a Webhook to your Bitbucket Cloud repository: **Bitbucket Cloud > Repository > Settings > Webhooks > Add Webhook**
   a. **Title**: Choose any title for your Webhook that aptly describes it.
   b. **URL**: Enter the URL of the Bamboo API to trigger a plan: `BAMBOO_URL/rest/triggers/1.0/remote/changeDetect?planKey=PLAN-KEY&skipBranches=false`
      i. Replace `BAMBOO_URL` with the URL of your Bamboo instance.
      ii. Replace `PLAN-KEY` with the key of the plan you wish to trigger. The `PLAN-KEY` is visible in the URL when browsing the plan in Bamboo. E.g. `https://bamboo.atlassian.com/browse/PLAN-KEY`
   c. **Triggers**: Choose the event(s) you want the Webhook to activate on. E.g. Repository Push.
   d. **Save**.

That's it! If you find your Webhook doesn't appear to be working – the best place to start troubleshooting is by viewing the request and response at **Bitbucket Cloud > Repository > Settings > Webhooks > View requests**.

### .Triggering a Bamboo build from Bitbucket Cloud using Webhooks v5.15

Webhooks provide a way to configure Bitbucket Cloud to make requests to your server (or another external service) whenever certain events occur in Bitbucket Cloud. The purpose of this guide is to help you set up a Webhook that will trigger a Bamboo build from Bitbucket Cloud after a certain event. For example, you may want Bitbucket Cloud to trigger a Bamboo build when your repository receives a commit (aka post-commit trigger).

**Procedure**

1. First configure the Bamboo plan to trigger with a `Remote trigger: Bamboo > Plan Configuration > Triggers > Add trigger > Remote trigger`.
2. Bamboo requires you to whitelist the IP addresses of the source of the request to trigger under the **Trigger IP Addresses field** (comma separated for each IP).
   a. The current list of Bitbucket Cloud IP addresses for outbound POST requests by Webhooks: **Bitbucket Cloud IP Addresses**
   b. CIDR Notation is only supported in Bamboo 5.14+
   c. Bamboo's IP whitelist also inspects the `X-Forwarded-For` HTTP header to determine the origin of the request. If you have a reverse proxy forwarding requests to your Bamboo instance, depending on its configuration, you may also need to whitelist the IP address of the Proxy Server.
3. Add a Webhook to your Bitbucket Cloud repository: **Bitbucket Cloud > Repository > Settings > Webhooks > Add Webhook**
   a. **Title**: Choose any title for your Webhook that aptly describes it.
   b. **URL**: Enter the URL of the Bamboo API to trigger a plan: `BAMBOO_URL/rest/triggers/1.0/remote/changeDetect?planKey=PLAN-KEY&skipBranches=false`
      i. Replace `BAMBOO_URL` with the URL of your Bamboo instance.
      ii. Replace `PLAN-KEY` with the key of the plan you wish to trigger. The `PLAN-KEY` is visible in the URL when browsing the plan in Bamboo. E.g. `https://bamboo.atlassian.com/browse/PLAN-KEY`
   c. **Triggers**: Choose the event(s) you want the Webhook to activate on. E.g. Repository Push.
   d. **Save**.

That's it! If you find your Webhook doesn't appear to be working – the best place to start troubleshooting is by viewing the request and response at **Bitbucket Cloud > Repository > Settings > Webhooks > View requests**.

### .Triggering a Bamboo build from Bitbucket Cloud using Webhooks v6.0

Webhooks provide a way to configure Bitbucket Cloud to make requests to your server (or another external service) whenever certain events occur in Bitbucket Cloud. The purpose of this guide is to help you set up a Webhook that will trigger a Bamboo build from Bitbucket Cloud after a certain event. For example, you may want Bitbucket Cloud to trigger a Bamboo build when your repository receives a commit (aka post-commit trigger).

**Procedure**

1. First configure the Bamboo plan to trigger with a `Remote trigger: Bamboo > Plan Configuration > Triggers > Add trigger > Remote trigger`.
2. Bamboo requires you to whitelist the IP addresses of the source of the request to trigger under the **Trigger IP Addresses field** (comma separated for each IP).
   a. The current list of Bitbucket Cloud IP addresses for outbound POST requests by Webhooks: **Bitbucket Cloud IP Addresses**
   b. CIDR Notation is only supported in Bamboo 5.14+
   c. Bamboo's IP whitelist also inspects the `X-Forwarded-For` HTTP header to determine the origin of the request. If you have a reverse proxy forwarding requests to your Bamboo instance, depending on its configuration, you may also need to whitelist the IP address of the Proxy Server.
3. Add a Webhook to your Bitbucket Cloud repository: **Bitbucket Cloud > Repository > Settings > Webhooks > Add Webhook**
   a. **Title**: Choose any title for your Webhook that aptly describes it.
   b. **URL**: Enter the URL of the Bamboo API to trigger a plan:
      `http://<your bamboo host>/api/rest/updateAndBuild.action?buildKey=<PLAN-KEY>`
      i. Replace `<your bamboo host>` with the URL of your Bamboo instance.
      ii. Replace `PLAN-KEY` with the key of the plan you wish to trigger. The `PLAN-KEY` is visible in the URL when browsing the plan in Bamboo. E.g. `https://bamboo.atlassian.com/browse/PLAN-KEY`
   c. **Triggers**: Choose the event(s) you want the Webhook to activate on. E.g. Repository Push.
   d. **Save**.

That's it! If you find your Webhook doesn't appear to be working – the best place to start troubleshooting is by viewing the request and response at **Bitbucket Cloud > Repository > Settings > Webhooks > View requests**.

### .Triggering a Bamboo build from Bitbucket Cloud using Webhooks v6.3

Created by Atlassian in 2018. Licensed under a [Creative Commons Attribution 2.5 Australia License](https://creativecommons.org/licenses/by/2.5/au/).
Webhooks provide a way to configure Bitbucket Cloud to make requests to your server (or another external service) whenever certain events occur in Bitbucket Cloud. The purpose of this guide is to help you set up a Webhook that will trigger a Bamboo build from Bitbucket Cloud after a certain event. For example, you may want Bitbucket Cloud to trigger a Bamboo build when your repository receives a commit (aka post-commit trigger).

**.Triggering a Bamboo build from Bitbucket Cloud using Webhooks v6.6**

Webhooks provide a way to configure Bitbucket Cloud to make requests to your server (or another external service) whenever certain events occur in Bitbucket Cloud. The purpose of this guide is to help you set up a Webhook that will trigger a Bamboo build from Bitbucket Cloud after a certain event. For example, you may want Bitbucket Cloud to trigger a Bamboo build when your repository receives a commit (aka post-commit trigger).

**Procedure**

1. First configure the Bamboo plan to trigger with a Remote trigger: Bamboo > Plan Configuration > Triggers > Add trigger > Remote trigger.
2. Bamboo requires you to whitelist the IP addresses of the source of the request to trigger under the Trigger IP Addresses field (comma-separated for each IP).
   a. The current list of Bitbucket Cloud IP addresses for outbound POST requests by Webhooks: Bitbucket Cloud IP Addresses
   b. CIDR Notation is only supported in Bamboo 5.14+
   c. Bitbucket's IP whitelist also inspects the X-Forwarded-For HTTP header to determine the origin of the request. If you have a reverse proxy forwarding requests to your Bamboo instance, depending on it’s configuration, you may also need to whitelist the IP address of the Proxy Server.
3. Add a Webhook to your Bitbucket Cloud repository: Bitbucket Cloud > Repository > Settings > Webhooks > Add Webhook
   a. Title: Choose any title for your Webhook that aptly describes it.
   b. URL: Enter the URL of the Bamboo API to trigger a plan:
      ```
      BAMBOO_URL/rest/triggers/1.0/remote/changeDetect
     离子?planKey=PLAN-KEY&skipBranches=false
      ```
      i. Replace **BAMBOO_URL** with the URL of your Bamboo instance.
      ii. Replace **PLAN-KEY** with the key of the plan you wish to trigger. The **PLAN-KEY** is visible in the URL when browsing the plan in Bamboo. E.g. https://bamboo.atlassian.com/browse/PLAN-KEY
      iii. **skipBranches true / false** will determine whether change detection will be triggered by this event for every branch on the plan (false), or just the plan key specified (true).
   c. Triggers: Choose the event(s) you want the Webhook to activate on. E.g. Repository Push.
   d. Save.

That's it! If you find your Webhook doesn't appear to be working – the best place to start troubleshooting is by viewing the request and response at Bitbucket Cloud > Repository > Settings > Webhooks > View requests.

**.Triggering builds v6.4**

Triggering in Bamboo allows plan builds to be started automatically. Bamboo has the following trigger methods:

- Trigger a build if code has changed:
  - Poll the repository for changes
  - A push to the repository triggers the build

- Trigger a build based on a schedule:
  - Cron-based scheduling
  - Single daily build

- Trigger a build depending on the outcome of other plans:
  - Plan builds are triggered by preceding successful builds of other plans.
  - Plan only builds if other specified plans are building successfully.
Choosing a triggering strategy

This table lists the ways in which plan builds can be triggered in Bamboo.

<table>
<thead>
<tr>
<th>Triggering option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Polling the repository for changes</strong></td>
<td>Bamboo will ‘poll’ the selected source code repositories for code changes, using either a specified interval (that is, periodically) or a schedule. If Bamboo detects code changes, a build of the plan is triggered.</td>
</tr>
<tr>
<td></td>
<td>• Your VCS must service a ‘check out’ or ‘update’ command whenever it is polled, even if no code has changed in a repository.</td>
</tr>
<tr>
<td></td>

</tbody>
</table>
Triggering builds v5.14
Triggering in Bamboo allows plan builds to be started automatically. Bamboo has the following trigger methods:

Trigger a build if code has changed:
- Poll the repository for changes
- A push to the repository triggers the build

Trigger a build based on a schedule:
- Cron-based scheduling
- Single daily build

Trigger a build depending on the outcome of other plans:
- Plan builds are triggered by preceding successful builds of other plans.
- Plan only builds if other specified plans are building successfully.

Note that a plan that has no configured triggers can only be started manually, or if it is dependent on the successful build of another plan.

From Bamboo 4.3, you can configure multiple triggers for each plan. This allows a plan to be triggered by different trigger types, and to have triggering scenarios such as "every 5 minutes between 9:00am and 10:00am, and every 20 minutes between 1:00pm and 10:00pm".

Triggers can only be configured by a Bamboo administrator.

Choosing a triggering strategy

This table lists the ways in which plan builds can be triggered in Bamboo.

<table>
<thead>
<tr>
<th>Triggering option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Polling the repository for changes</td>
<td>Bamboo will 'poll' the selected source code repositories for code changes, using either a specified interval (that is, periodically) or a schedule. If Bamboo detects code changes, a build of the plan is triggered.</td>
</tr>
<tr>
<td>Repository triggers the build when changes are committed</td>
<td>Bamboo waits to receive a message about changed code from any of the selected source code repositories. When Bamboo receives such a message, a build of the plan is triggered.</td>
</tr>
</tbody>
</table>

- Your VCS must service a 'check out' or 'update' command whenever it is polled, even if no code has changed in a repository.

See Polling the repository for changes.

See Repository triggers the build when changes are committed.
### Cron-based scheduling

Bamboo will trigger scheduled builds of this plan based on a cron expression.

- This option allows you to schedule builds when server load is likely to be minimal, for example, outside office hours.
- Scheduled builds are triggered irrespective of any code changes in the source code repositories.

See [Cron-based scheduling](#).

### Single daily build

Bamboo will trigger a build of the plan once per day at a specified time.

- Can be set up to run at a time of your choice.
- This option is suitable if a build of this plan takes a long time to complete.
- Scheduled builds are triggered irrespective of any code changes in the source code repositories.

See [Single daily build](#).

---

### Conditional build triggers

*This feature is only available when configuring an existing plan.*

You can choose to run builds of this plan only if other specified plans are currently passing. Those plans must build successfully before this plan will be built. See also [Setting up plan build dependencies](#).

Note that, because a plan may have multiple triggers configured, each of which can have differing trigger conditions, it is possible for the plan build to be started by one trigger, even though another trigger is currently blocked.

**To specify build trigger conditions:**

1. Choose **Build > All build plans** from the Bamboo header.
2. Locate the plan in the list and click the edit icon (`.edit`)
3. Click the **Triggers** tab, and click either an existing trigger or **Add trigger**.
4. Select **Only run Build if other Plans are currently passing**, under 'Trigger conditions'.
5. Specify one or more other plans by adding their full keys.

### Trigger conditions

- **Only run Build if other Plans are currently passing**

**Plan Keys**

![FULL_KEY](FULL_KEY)

Enter comma separated Plan Keys.

---

### Using stages in a plan

*Stages* group (or ‘map’) jobs to individual steps within a *plan’s build process*. For example, you may have an overall plan build process that comprises a compilation step, followed by several test steps, followed by a deployment step. You can create separate Bamboo stages to represent each of these steps.

**A stage:**

- Has a single job, by default, but can be used to group multiple jobs.
- Processes its jobs in parallel, on multiple agents (where available).
- Must successfully complete all its jobs before the next stage in the plan can be processed.
- May produce artifacts that can be made available for use by a subsequent stage.

Each new plan created in Bamboo contains at least one stage (for the *default job*) and is known as the ‘Default Stage’. Stages can only be configured by Bamboo administrators.
About manual stages

Any stage in a plan can be configured to be a manual stage. If you run a plan with manual stages, Bamboo will pause the execution of the plan every time it reaches a manual stage. The plan build will only continue once a user has manually triggered the stage. Please note:

- A manual stage can only be triggered if the previous stage has completed successfully.
- Manual stages must be executed in the order that they are configured in the plan. You cannot skip a manual stage.
- Manual stages will be displayed in the Plan Navigator with either this icon (not due to be triggered) or this icon (pending execution).
- You need 'Build' permission on the plan to run a manual stage.

Navigate to the stages for a plan

To navigate to the stages for a plan:

1. Choose Build > All build plans from the Bamboo header, then click the name of the plan you want to edit.
2. Choose Actions > Configure Plan.
3. Click the Stages tab.

Create a stage

1. Navigate to the stages for the plan, as described above.
2. Click Create Stage, at the right.
3. Complete the form and click Create. For information about manual stages, see About manual stages above.
4. (optional) You may want to do one or more of the following with your new stage:
   - Order your new stage in the list of stages, by dragging and dropping it.
   - Add a new job to your stage.
   - Move a job from another stage to your new stage by dragging and dropping the job.

Note that you may break artifact dependencies by moving stages, or by moving jobs between stages. Bamboo will warn you, if a dependency will be broken by moving a stage or a job.

Edit a stage

1. Navigate to the stages for the plan, as described above.
2. Edit the stage as required:
   - To edit the name and description of the stage or configure whether it is a manual stage, click the cog icon and choose Configure stage.
   - To move the stage, drag and drop the stage to the desired place in the plan.

Note that you may break artifact dependencies by moving stages. Bamboo will warn you if a dependency will be broken by moving a stage.

Delete a stage

Before you begin, please understand that:

- Deleting a stage will delete all job configurations, artifacts, logs and results related to the stage. These cannot be recovered after the stage is deleted.
- You may break artifact dependencies by deleting a stage.

To delete a stage:

1. Navigate to the stages for the plan, as described above.
2. Click the cog icon for the relevant stage and choose Delete stage.
3. Click Confirm to delete the stage. Note that a deleted stage cannot be recovered.

Jobs and tasks

The following pages contain information about configuring jobs and tasks for your Bamboo plans. If you are looking for information about Bamboo builds, please see Working with builds.

- Creating a job
- Configuring jobs
- Disabling or deleting a job
- Configuring tasks

Jobs

A Bamboo job is a single build unit within a plan. One or more jobs can be organized into one or more stages. The jobs in a stage can all be run at the same time, if enough Bamboo agents are available. A job is made up of one or more tasks.

A job:
- Processes a series of one or more tasks that are run sequentially on the same agent.
- Controls the order in which tasks are performed.
- Collects the requirements of individual tasks in the job, so that these requirements can be matched with agent capabilities.
- Defines the artifacts that the build will produce.
- Can only use artifacts produced in a previous stage.
- Specifies any labels with which the build result or build artifacts will be tagged.

Each new plan created in Bamboo contains at least one job known as the 'Default Job'.

Projects and plans can only be configured by Bamboo administrators (see Creating a plan).

Tasks

A task:
- Is a small discrete unit of work, such as source code checkout, executing a Maven goal, running a script, or parsing test results.
- Is run sequentially within a job on a Bamboo working directory.

Tasks may make use of an executable if required. Tasks are configured within the scope of a job. A job can be configured to execute a number of tasks, on the same working directory. For example, before executing a Maven goal, the user could substitute specific files within the working directory, substitute version numbers, check out source repositories, or execute a script.

Final tasks for a job are always executed, even if previous tasks in the job failed.

Screenshot: Configuring tasks for a job
Creating a job

This page describes how to create a Bamboo job in a stage of a plan.

- You can either create a new job, or clone an existing job.
- You must have the 'Admin' or 'Create Plan' global permission to create jobs.
- A job allows you to collect together a number of tasks that you want to be run sequentially on the same agent.

**Related pages:**
- Configuring plans
- Using stages in a plan
- Configuring jobs
- Disabling or deleting a job

To create a new job for a plan:

1. Click Dashboard and then the All Plans tab.
2. Click the name of the plan in the list.
3. Choose Actions > Configure Plan.
4. Click on the Stages tab.
5. Click Add Job in the stage where you want the new job.
6. Click either Create a new job or Clone an existing job.
7. If cloning a job, complete the 'Job to clone from' section:
   - **Plan to clone from** — Select the plan containing the job you wish to clone. Plans are grouped by project in the list.
   - **Job to clone** — Select the job you wish to clone from your selected plan. Jobs are grouped by stage in the list.
8. Complete the 'Job Details' section.
9. Select Yes please! to enable this job, if required. Enabling the job instructs Bamboo to execute the job whenever the job's plan is built.
10. Click Create Job.

If you wish to configure tasks for the job, such as configuring a Repository Checkout, please refer to Configuring jobs.

Screenshot: Creating a new job

. Creating a job v5.14

This page describes how to create a Bamboo job in a stage of a plan.

- You can either create a new job, or clone an existing job.
- You must have the 'Admin' or 'Create Plan' global permission to create jobs.
- A job allows you to collect together a number of tasks that you want to be run sequentially on the same agent.
To create a new job for a plan:

1. Click Dashboard and then the All Plans tab.
2. Click the name of the plan in the list.
3. Choose Actions > Configure Plan.
4. Click on the Stages tab.
5. Click Add Job in the stage where you want the new job.
6. Click either Create a new job or Clone an existing job.
7. If cloning a job, complete the ‘Job to clone from’ section:
   - Plan to clone from — Select the plan containing the job you wish to clone. Plans are grouped by project in the list.
   - Job to clone — Select the job you wish to clone from your selected plan. Jobs are grouped by stage in the list.
8. Complete the ‘Job Details’ section.
9. Select Yes please! to enable this job, if required. Enabling the job instructs Bamboo to execute the job whenever the job’s plan is built.
10. Click Create Job.

If you wish to configure tasks for the job, such as configuring a Repository Checkout, please refer to Configuring jobs.

Creating a job v6.4

This page describes how to create a Bamboo job in a stage of a plan.

- You can either create a new job, or clone an existing job.
- You must have the 'Admin' or 'Create Plan' global permission to create jobs.
- A job allows you to collect together a number of tasks that you want to be run sequentially on the same agent.

To create a new job for a plan:

1. Click Dashboard and then the All Plans tab.
2. Click the name of the plan in the list.
3. Choose Actions > Configure Plan.
4. Click on the Stages tab.
5. Click Add Job in the stage where you want the new job.
6. Click either Create a new job or Clone an existing job.
7. If cloning a job, complete the ‘Job to clone from’ section:
   - Plan to clone from — Select the plan containing the job you wish to clone. Plans are grouped by project in the list.
   - Job to clone — Select the job you wish to clone from your selected plan. Jobs are grouped by stage in the list.
8. Provide your job details.
9. Select if you want to run your job in the agent environment or in a docker container. See Docker Runner
10. Click Create Job.

If you wish to configure tasks for the job, such as configuring a Repository Checkout, see Configuring jobs.

Screenshot: Creating a new job

Configuring jobs

A Bamboo job is a single build unit within a plan. One or more jobs can be organized into one or more stages. The jobs in a stage can all be run at the same time, if enough Bamboo agents are available. A job allows you to collect together a number of tasks that you want to be run sequentially on the same agent.

You must have the ‘Admin’ or ‘Create Plan’ global permission to configure jobs.

Related pages:
- Creating a job
- Disabling or deleting a job
- Viewing a job’s Maven dependencies

To configure an existing job in a Bamboo plan:

1. Go to the configuration pages for the plan that has the job.
2. Click on the required job (under ‘Stages & Jobs’), and then appropriate tab to begin editing that aspect of your job:

   - Job Details — Note that Job Key is not editable.
   - Tasks — see Configuring tasks, including Repository Checkout tasks and builder tasks.
   - Requirements — see Configuring a job’s requirements.
   - Artifacts — see Configuring a job’s build artifacts.
   - Miscellaneous — see Configuring miscellaneous settings for a job and Configuring automatic labeling of build results.

Configuring a job’s requirements

This page describes how to configure the requirements of a job.

A requirement is specified in a job or a task. A requirement specifies a capability that an agent must have for it to build that job or task. A job inherits all of the requirements specified in its tasks.
Together, capabilities and requirements control which agents can execute builds for particular jobs. Each job can only be built by agents whose capabilities match the job's requirements.

There are four types of capabilities in Bamboo that can be specified by job and task requirements:

- **Executable capabilities** — Define external programs that can be called by Bamboo, for example Ant, Maven, MSBuild or PHPUnit. See [Defining a new executable capability](#).
- **JDK capabilities** — Define the JDK versions to be used by the job or task. See [Defining a new JDK capability](#).
- **Version control capabilities** — Specify the VCS client application that Bamboo should use to check out source code. See [Defining a new version control capability](#).
- **Custom capabilities** — Can be used to control which jobs will be built by a particular agent. For example, if the builds for a particular job should only run in a Windows environment, you could create a custom capability of 'operating.system=WindowsXP' for the appropriate agent(s), and specify it as a requirement for this job. See [Defining a new custom capability](#).

Before you can specify a requirement in your job, you must first define that capability in your Bamboo system.

### Specifying extra requirements for a job

A job will inherit the requirements of its tasks by default. However, you can specify extra requirements for a job, in addition to its task requirements.

To specify extra requirements for a job:

1. Navigate to the desired job's configuration pages, as described on Configuring jobs.
2. Click the Requirements tab (see screenshot below). This page shows a list of all the job's current requirements and the number of 'Matching Agents' and 'Matching Images' (i.e. agents/elastic images which meet the job's requirements and can run a build for this job). See [Viewing current capable agents](#) for more information.
3. If you have previously set up an agent capability, you can select it from the Requirement list in the 'Add Extra Requirement' section.
4. If you are setting up a new custom requirement, select New custom requirement from that list instead.
5. Complete the form for the requirement:
   a. **Key (new custom requirement only)** — enter a key of the new capability.
   b. Select the value for the requirement from the list:
      - **exists** — this job can be built by any agent that has a capability with the same key.
      - **equals** — this job can be built by any agent that has the capability with the same key and value.
      - **matches** — this job can be built by any agent that has a capability with the same key, and the value matches the regular expression. For more information about regular expressions, see Oracle's tutorial on regular expressions.
6. Click Add. The numbers of 'Matching Agents' and 'Matching Images' will be updated, as the plan can now only be built by agents with capabilities that meet the new custom requirement you have specified.

### Screenshot: Specifying requirements for a job

<table>

Add Cancel
Viewing current capable agents

To view details about agents or elastic images that are currently able to build your job:

1. On the job's Requirements tab (described above), click the name of the requirement in the table (e.g. 'Maven 2').
2. The summary page for the capability will be displayed, showing the agents and elastic images that have the capability. See Viewing a capability's agents and jobs for more information.

Configuring a job's build artifacts

Artifacts are files created by a job build (e.g. JAR files). Artifact definitions are used to specify which artifacts to keep from a build and are configured for individual jobs.

See Sharing artifacts.

This page describes how to define the artifacts that should be kept from a job's build. For example, you may wish to keep reports, websites or files (e.g. JAR files) generated by a job build.

You can also configure artifact sharing between jobs in a plan. For example, you may want to run acceptance tests on a build, and then share the WAR from one job to another, without rebuilding the WAR each time. See Sharing artifacts.

Define the artifacts to keep for a job

You can specify which artifacts to keep by setting up an artifact definition for the job. The artifacts will be available after each build of a job.

To set up an artifact definition for a job:

1. Navigate to the desired job, as described on Configuring jobs.
2. Click the Artifacts tab, and then Create Definition.
3. Complete the fields on the screen (see screenshot below) and click Create. For example, if you want to keep the latest version of a JAR you have built, you could specify Copy Pattern to be '*.jar' and the Location to be 'target'.

Please note:
- The location is relative to the build directory. Do not use the absolute path to refer to the location.
- The copy pattern is relative to the location specified.
- Asterisks are not supported for Location. For this field, provide the folder name where the file would be located.
- If you want to share artifacts with other jobs in the plan, you will need to mark the artifacts as shared. See Sharing artifacts.

Screenshot: Creating an artifact definition

Create definition

Create a new artifact definition

Name* Latest JAR

If the artifact is shared, the name must be unique within the plan

Location target

Specify the directory (relative path) to find your artifact. e.g. target

Copy pattern* 

Specify the name (or Ant file copy pattern) of the artifact(s) you want to keep. e.g. '**.jar'

Shared

Make the artifact available to be used in other builds and deployments.

Create Cancel
**Notes**

Artifacts are copied to a subdirectory (/JOB_KEY/download-data/) under your 'Build Directory' folder (see Locating important directories and files). Artifacts which you define in the plan are listed in each build result as artifacts (see Viewing a build's artifacts).

Configuring a job’s build artifacts v5.14

Artifacts are files created by a job build (e.g. JAR files). Artifact definitions are used to specify which artifacts to keep from a build and are configured for individual jobs.

and files). Artifacts which you define in the plan are listed in each build result as *artifacts* (see Viewing a build’s artifacts).

### Configuring miscellaneous settings for a job

For each job of a plan, you can optionally specify a number of miscellaneous settings including:

- **Build hanging detection**
- **NCover output**
- **Clover code coverage**

To configure the miscellaneous settings for a job:

1. Navigate to the desired job, as described in Configuring jobs.
2. Edit the desired settings as follows: **Override default hanging build detection**
   
   Override the default build hanging detection settings. These settings determine when a build hung event is thrown (e.g. you can configure your notifications to trigger from this event).

   **Build Time Multiplier** — Calculate the ‘Expected Build Time’ for the build (i.e. ‘Expected Build Time’ = ‘Build Time Multiplier’ multiplied by ‘Average Build Time’). ‘Average Build Time’ is calculated by using an average of previous build times.

   **Log Quiet Time** — The amount of time since Bamboo last recorded an entry in the build log for a build. The ‘Expected Build Time’ and ‘Log Quiet Time’ must both be exceeded for Bamboo to throw the build hung event.

   **Build Queue Timeout** — The amount of time that a build will wait in a build queue before an timeout event is thrown. Setting this value will override the global build queue timeout setting (see Configuring the build queue timeout event).

**NCover output will be produced**

*Do not select this option. NCover is a code coverage tool that supports .NET projects.*

**Use Clover to collect Code Coverage for this build**

Select this check box if:

- This job will be building a Java or Groovy-based project using a builder such as Ant, Maven or Grails.
- You are running Atlassian Clover and want to collect code coverage data to view from within Bamboo (see Viewing the Clover code-coverage for a build).

**Automatically integrate Clover into this build**

- **Generate a Clover Historical Report** — shows the current coverage results compared with previous Clover code coverage reports.
- **Generate a JSON report** — gives the Clover results in a format ready for embedding into applications or external report views.

You will also need to insert a Clover license (evaluation licenses are available) into the field provided. See Enabling the Clover add-on.

**Clover is already integrated into this build and a clover.xml file will be produced**

Use this option when you already have Clover-for-Ant or Clover-for-Maven configured to generate a report.

- **Clover XML Location** — specify where the Clover XML report is generated. Include the name of the directory, including path, relative to your job build's root directory, for example: `target/site/clover/clover.xml`

3. Click **Save**.

### Configuring automatic labeling of job build results

For each job of a plan, you can (as an option) specify a label that can be applied to the job’s build results automatically after each build of that job.

Automatic labeling of job builds is built into Bamboo itself. There are a number of third-party plugin modules available that can provide additional ‘post’ actions (e.g. the Pre-Post Build Command plugin). You can also write your own plugins to provide additional post actions for a job. See the Bamboo Plugin Guide for further details.

Labels can also be applied to build results manually by Bamboo users.

**On this page:**

- Specifying labels for a job’s build results
- Regex examples

**Related pages:**

- Configuring jobs

### Specifying labels for a job’s build results

**To specify labels for a job’s build results:**

1. Navigate to a job’s configuration pages, as described on Configuring jobs.
2. Click the **Miscellaneous** tab.
3. Using **Regex Pattern**, you can either:

   - Specify a regular expression to match content in the log files of this job’s builds. Labels will be applied to a build of this job if this regular expression matches content in the build’s log files (see the examples below).

     **For more information about regular expressions, please refer to the Java documentation on regular expression constructs.**

     Leave this field blank to label every build of this job.
4. In the **Labels** field, type the word (or multiple words, separated by commas and/or spaces) with which the plan’s build results are to be labeled.
5. Click **Save**.

**Regex examples**

**A simple regex example:**

```plaintext
'There are \d+ results'
```

In the above regex, "\d+" represents *any number with one or more digits*. ("\d" means 'any digit', and '+' means 'one or more times'.) Therefore, positive matches would include:

- 'There are 0 results'
- 'There are 123 results'

**A regex example with multiple labels:**

You can use "capturing groups" with Bamboo 1.2.1 or later to create different labels for different purposes.

For example, the following settings will label your builds with PERFORMANCE_IMPROVED if "PERFORMANCE_IMPROVED" appears in the build log, and PERFORMANCE_DETERIORATED if "PERFORMANCE_DETERIORATED" appears in the build log. If both strings appear in a log, then both labels are applied to the build.

- Enter the following into the **Regex Pattern** field:
  ```plaintext
  (PERFORMANCE_IMPROVED|PERFORMANCE_DETERIORATED)
  ```

- Enter the following into the **Labels** field:
  ```plaintext
  \1
  ```

**Viewing a job’s Maven dependencies**

If you have configured a job to use a Maven builder (Maven 2 or later), you can choose to have dependencies generated from your Maven pom.xml (see documentation for setting up Maven as a builder for instructions). After the initial build, Maven will parse the pom.xml file, determine the artifacts produced by the build and generate the dependencies. You can view these dependencies in two places:

- On the **Dependencies** tab when configuring your plan, as described in Setting up plan build dependencies.
- On the **Artifacts** tab when viewing a job’s build result, as described below.

Before you begin:

- The Maven dependencies for a build will only become known to Bamboo after a build. If you cannot see the Maven dependencies for a build, try running it first without triggering any other dependencies. See Modifying multiple plans in bulk if you want to run multiple builds.

**To view the Maven dependencies for a job’s build result:**

1. Navigate to the desired job, as described on Configuring jobs.
2. Click the desired build result number in the ‘Recent History’ of the Job Summary.
3. Click the **Artifacts** tab for the build results. The produced Maven artifacts and Maven artifact dependencies will be listed.

Screenshot: Maven 2 dependencies for a job’s build result
1. Configuring jobs v6.4

A Bamboo job is a single build unit within a plan. One or more jobs can be organized into one or more stages. The jobs in a stage can all be run at the same time if enough Bamboo agents are available. A job allows you to collect together a number of tasks that you want to be run sequentially on the same agent.

You must have the 'Admin' or 'Create Plan' global permission to configure jobs.

**Related pages:**
- Creating a job
- Disabling or deleting a job
- Viewing a job's Maven dependencies

**To configure an existing job in a Bamboo plan:**

1. From the top menu bar, choose **Build > All build plans**.
2. Click the edit icon ( ) for the plan you want to edit.
3. Click on the required job (under 'Stages & Jobs'):
   - Click on a selected tab to begin editing that aspect of your job:
     - **Job Details** — Note that Job Key is not editable.
     - **Docker** — see Docker Runner.
     - **Tasks** — see Configuring tasks, including Repository Checkout tasks and builder tasks.
     - **Requirements** — see Configuring a job's requirements.
     - **Artifacts** — see Configuring a job's build artifacts.
     - **Miscellaneous** — see Configuring miscellaneous settings for a job and Configuring automatic labeling of build results.
Configuring jobs v5.14

A Bamboo job is a single build unit within a plan. One or more jobs can be organized into one or more stages. The jobs in a stage can all be run at the same time, if enough Bamboo agents are available. A job allows you to collect together a number of tasks that you want to be run sequentially on the same agent.

You must have the 'Admin' or 'Create Plan' global permission to configure jobs.

Related pages:
- Creating a job
- Disabling or deleting a job
- Viewing a job's Maven dependencies

To configure an existing job in a Bamboo plan:

1. Go to the configuration pages for the plan that has the job.
2. Click on the required job (under 'Stages & Jobs'), and then appropriate tab to begin editing that aspect of your job:
   - **Job Details** — Note that Job Key is not editable.
   - **Tasks** — see Configuring tasks, including Repository Checkout tasks and builder tasks.
   - **Requirements** — see Configuring a job's requirements.
   - **Artifacts** — see Configuring a job's build artifacts.
   - **Miscellaneous** — see Configuring miscellaneous settings for a job and Configuring automatic labeling of build results.

Disabling or deleting a job

Bamboo allows you to disable or delete jobs that you don't want to be built.

Disabling a job

Disabling a job prevents Bamboo from building that particular job within a plan, allowing the rest of the plan’s jobs to be built. You can re-enable the job, if you want to build it again.

For example, if a job’s latest build is broken and cannot be fixed quickly, you may want to disable it temporarily to stop the job from being built.

Deleting a job

Deleting a job deletes everything related to that job, including the job’s configuration, build results, artifacts, labels and comments. However, everything else related to the job’s plan, and this plan’s other jobs, is retained by Bamboo.

You will need to recreate a new job from scratch, if you want to build it again.

For example, if a job is no longer relevant, you may want to delete it.

Note that:
- The 'Admin' global permission is required to delete a job.
- A job that is currently being built cannot be deleted. If you need to delete such a job, stop the plan’s build first. Refer to Stopping an active build for more information.
- If you need to keep a permanent record of your job’s build results, see Exporting data for backup.

Related pages:
- Creating a job
- Configuring jobs
- Disabling or deleting a plan
- 2018-02-07_10-47-50_Deleting a job's current working files

Disable or delete a job

1. Navigate to the job configuration, as described on Configuring jobs.
2. Choose either Actions > Disable Job or Actions > Delete Job.

Disabling or deleting a job v5.14

Bamboo allows you to disable or delete jobs that you don't want to be built.

Disabling a job

Disabling a job prevents Bamboo from building that particular job within a plan, allowing the rest of the plan's jobs to be built. You can re-enable the job, if you want to build it again.

For example, if a job's latest build is broken and cannot be fixed quickly, you may want to disable it temporarily to stop the job from being built.

Deleting a job
Deleting a job deletes everything related to that job, including the job's configuration, build results, artifacts, labels and comments. However, everything else related to the job's plan, and this plan's other jobs, is retained by Bamboo.

You will need to recreate a new job from scratch, if you want to build it again. For example, if a job is no longer relevant, you may want to delete it.

Note that:

- The 'Admin' global permission is required to delete a job.
- A job that is currently being built cannot be deleted. If you need to delete such a job, stop the plan's build first. Refer to Stopping an active build for more information.
- If you need to keep a permanent record of your job's build results, see Exporting data for backup.

Enable or delete a job

1. Navigate to the job configuration, as described on Configuring jobs.
2. Choose either Actions > Disable Job or Actions > Delete Job.

Configuring tasks

A task:

- Is a small discrete unit of work, such as source code checkout, executing a Maven goal, running a script, or parsing test results.
- Is run sequentially within a job on a Bamboo working directory.

Tasks may make use of an executable if required. Tasks are configured within the scope of a job. A job can be configured to execute a number of tasks, on the same working directory. For example, before executing a Maven goal, the user could substitute specific files within the working directory, substitute version numbers, check out source repositories, or execute a script.

Final tasks for a job are always executed, even if previous tasks in the job failed.

Create a task for a job

When creating a new job or configuring an existing one, you need to specify the tasks that will execute the job's builds. You must specify an executable for each task. If you specify an Ant, Grails or Maven executable, you will also need to choose a JDK.

When creating a new plan, you can configure the tasks for the plan's default job.
5. Click **Save**.

**Screenshot: Specifying a task for a job — Task types**

Order the tasks in a job

Tasks can be designated as **build tasks** or **final tasks** in a job:

- Build Tasks will run sequentially in the order specified in the job. If a Build Task fails, all subsequent tests will not be executed.
- Final Tasks will run sequentially, once the build tasks have completed. Final Tasks will always be executed, regardless of whether any Build Tasks or other Final Tasks fail. Final Tasks will be executed even if you stopped the build manually.

To order the tasks for a job:

1. Navigate to the tasks for the desired job.
2. Drag and drop the tasks into the desired order in the table on the left. If you want to change a Build Task to a Final Task or vice versa, drag and drop it under the desired header in the table. Your changes will be saved immediately.

**Screenshot: Existing Task — Command Task**

Notes

- **Adding new executables** — At least one executable is configured automatically after installing Bamboo. You can add more executables of different types as described in Configuring a new executable.
- **Adding new JDKs** — At least one JDK is configured automatically after installing Bamboo. You can add more JDKs as described in
Defining a new JDK capability.

- About the 'Compatibility Task' — The 'Compatibility Task' is created by Bamboo when upgrading from Bamboo 3.0 or earlier and Bamboo cannot match a builder to a task. This may occur if you are using a builder enabled by a custom plugin.

Checking out code

You use the Source Code Checkout task to check out a repository for use by just one job. By default, repositories are checked out to the Bamboo working directory.

Using Source Code Checkout task you can also:

- Check out repositories to a custom directory path in the working directory.
- Specify multiple checkouts that occur at different stages of the build. (Simply add another Source Code Checkout task to a job at any point in the plan.)

For information about specifying a repository for use by all the plan’s jobs, or by all plans, see Linking to code repositories.

To configure a new Source Code Checkout task:

1. Navigate to the job that should perform the task.
2. Click the Tasks tab, and select an existing 'Source Code Checkout' task in the tasks list, or add a new one using the Add Task button.
3. Configure the task:
   - Task Description
     Enter a description of the task, for display in Bamboo.
   - Disable this task
     Check, or clear, to selectively run this task.
   - Repository
     Select the desired repository. If you wish to add different types of repositories, they must have been previously defined on the plan’s Source Repositories tab. See Linking to source code repositories for a list of supported SCMs.
   - Checkout Directory
     The location to which the contents of the selected repository will be checked out to when the task executes.
   - Force Clean Build
     Deletes the previously checked out directory and checks it out again prior to the next build. This may significantly increase build times.
4. Click Add repository, at the bottom of the 'Task' screen, to check out another repository using this task.
5. Click Save.

Screenshot: Configuring a Source Code Checkout task

Notes

- A number of source repositories are supported 'out of the box', as described on the Linking to code repositories page.
- If you need to use a type of repository that is not supported, a number of third-party Source Repository plugin modules are available (e.g. ClearCase plugin). You can also write a Source Repository Module plugin to enable Bamboo to connect to your repository.

Checking out code v5.14

You use the Source Code Checkout task to check out a repository for use by just one job. By default, repositories are checked out to the Bamboo working directory.
Using Source Code Checkout task you can also:

- Check out repositories to a custom directory path in the working directory.
- Specify multiple checkouts that occur at different stages of the build. (Simply add another Source Code Checkout task to a job at any point in the plan.)

For information about specifying a repository for use by all the plan's jobs, or by all plans, see Linking to code repositories.

**To configure a new Source Code Checkout task:**

1. Navigate to the job that should perform the task.
2. Click the **Tasks** tab, and select an existing 'Source Code Checkout' task in the tasks list, or add a new one using the **Add Task** button.
3. Configure the task:

<table>
<thead>
<tr>
<th>Task Description</th>
<th>Enter a description of the task, for display in Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable this task</td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the desired repository. If you wish to add different types of repositories, they must have been previously defined on the plan's <strong>Source Repositories</strong> tab. See <strong>Linking to source code repositories</strong> for a list of supported SCMs.</td>
</tr>
<tr>
<td>Checkout Directory</td>
<td>The location to which the contents of the selected repository will be checked out to when the task executes.</td>
</tr>
<tr>
<td>Force Clean Build</td>
<td>Deletes the previously checked out directory and checks it out again prior to the next build. This may significantly increase build times.</td>
</tr>
</tbody>
</table>

4. Click **Add repository**, at the bottom of the 'Task' screen, to check out another repository using this task.
5. Click **Save**.

**Screenshot: Configuring a Source Code Checkout task**

A number of source repositories are supported 'out of the box', as described on the [Linking to code repositories](https://docs.atlassian.com/bamboo/overview/) page.

If you need to use a type of repository that is not supported, a number of third-party Source Repository plugin modules are available (e.g. ClearCase plugin). You can also write a Source Repository Module plugin to enable Bamboo to connect to your repository.

**Checking out code v6.1**

You use the Source Code Checkout task to check out a repository for use by just one job. By default, repositories are checked out to the Bamboo working directory.

Using Source Code Checkout task you can also:

- Check out repositories to a custom directory path in the working directory.
- Specify multiple checkouts that occur at different stages of the build. (Simply add another Source Code Checkout task to a job at any point in the plan.)

For information about specifying a repository for use by all the plan's jobs, or by all plans, see [Linking to code repositories](https://docs.atlassian.com/bamboo/overview/).
To configure a new Source Code Checkout task:

1. Navigate to the job that should perform the task.
2. Click the Tasks tab, and select an existing 'Source Code Checkout' task in the tasks list, or add a new one using the Add Task button.
3. Configure the task:
   
   **Task Description**
   Enter a description of the task, for display in Bamboo.

   **Disable this task**
   Check, or clear, to selectively run this task.

   **Repository**
   Select the desired repository. If you wish to add different types of repositories, they must have been previously defined on the plan's Source Repositories tab. See Linking to source code repositories for a list of supported SCMs.

   **Checkout Directory**
   The location to which the contents of the selected repository will be checked out to when the task executes.

   **Force Clean Build**
   Deletes the previously checked out directory and checks it out again prior to the next build. This may significantly increase build times.

4. Click Add repository, at the bottom of the 'Task' screen, to check out another repository using this task.
5. Click Save.

Screenshots: Configuring a Source Code Checkout task

Notes

- A number of source repositories are supported ‘out of the box’, as described on the Linking to code repositories page.
- If you need to use a type of repository that is not supported, a number of third-party Source Repository plugin modules are available (e.g. ClearCase plugin). You can also write a Source Repository Module plugin to enable Bamboo to connect to your repository.

Configuring a builder task

A builder task allows you to connect your Bamboo plan (or job) to a build tool such as Ant, Maven or MSBuild. The build tool uses its existing configuration when the plan (or job) is built.

You can connect Bamboo to the following build tools:

- Ant
- Custom command executable
- Fastlane
- Grails
- Maven
- MSBuild
- NAnt
- Script
- Visual Studio
- Xcode
Ant

This page describes how to configure a Bamboo task to use Ant.

See Configuring a builder task for an overview of Bamboo builder tasks.

To configure an Ant task:
1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing Ant task, or click Add Task and then Ant to create a new task.
3. Complete the following settings:

   Task Description
   A description of the task, which is displayed in Bamboo.

   Disable this task
   Check, or clear, to selectively run this task.

   Executable
   The Ant executable that is available to perform the task. The executable that you select will become one of the task's (and so, the job's) requirements.

   You can add other executables, if required.

   Build File
   The name of your existing build file (e.g. build.xml).
   You can include variables (see Using Global or Build-specific Variables).
**Target**
The Ant target that you want this Bamboo task to execute (e.g. test). You can use `-D` to define one or more JVM parameters (e.g.: `--Djava.awt.headless="true"`). You must use double quotes around the parameter value; single quotes are considered as part of the actual value. Multiple Ant targets can be specified with a space-delimited list. You can also include variables (see Using Global or Build-specific Variables).

**Build JDK**
The JDKs that are available to perform the task. The JDK that you select will become one of the task’s (and so, the job’s) requirements. You can add other JDKs, if required.

**Environment Variables** (Optional)
Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Using Global or Build-specific Variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g ANT_OPTS="-Xms200m -Xmx700m").

**Working Sub Directory** (Optional)
An alternative subdirectory, relative to the job’s root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job’s configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

**The build will produce test results**
Select to specify the directory, relative to the root directory, where test results will be created. You can use Ant-style patterns such as `**/test-results/*.xml`. Bamboo requires test results to be in JUnit XML format.

For jobs that use CVS, the root directory is `<bamboo-home>/xml-data/build-dir/JOB_KEY/<cvs-module>`.

4. Click Save.

**Ant v5.14**
This page describes how to configure a Bamboo task to use Ant. See Configuring a builder task for an overview of Bamboo builder tasks.

**Related pages:**
- Configuring tasks
- Configuring jobs
- Pattern matching reference

**To configure an Ant task:**
1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing Ant task, or click Add Task and then Ant to create a new task.
3. Complete the following settings:

<table>
<thead>
<tr>
<th>Task Description</th>
<th>A description of the task, which is displayed in Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable this task</td>

**Custom command executable v6.1**

This page describes how to configure a Bamboo task that uses a command (e.g. Bash) executable.

See [Configuring a builder task](#) for an overview of Bamboo builder tasks.

---

**To configure a command task:**

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing Command task, or click **Add Task** and then **Command** to create a new task.
3. Complete the following settings:

   **Task Description**
   
   A description of the task, which is displayed in Bamboo.

   **Disable this task**
   
   Check, or clear, to selectively run this task.

   **Executable**
   
   The command executable that is available to perform the task (e.g. Bash). The executable that you select will become one of the task's (and so, the job's) requirements.
You can add other executables, if required.

**Argument** (Optional)
The relevant argument to pass to the command. Note that arguments which contain spaces must be quoted. You can include variables (see Bamboo variables).

**Environment Variables** (Optional)
Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Using global, plan or build-specific variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g ANT_OPTS="-Xms200m -Xmx700m").

**Working Sub Directory**
(Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

4. Click **Save**.

**Fastlane**

This page describes how to configure a Bamboo task to use Fastlane.

To configure a Fastlane task:

1. Go to the **Tasks** configuration tab for the job.
2. Click the **Add task** button.
   - From the list of task types, select **Fastlane**.
3. Provide the Fastlane settings:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tasks Description</td>
<td>A description of the task, which is displayed in Bamboo.</td>
</tr>
<tr>
<td>Disable this task</td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
<tr>
<td>Executable</td>
<td>The executable that is available to perform the task. The executable that you select will become one of the task's (and so, the job's) requirements.</td>
</tr>
<tr>
<td>Lane</td>
<td>The lane you want to execute. This field also allows you to define Fastlane properties such as param:paramValue.</td>
</tr>
<tr>
<td>Environment variables</td>
<td>Extra parameter variables. You can define multiple variables.</td>
</tr>
<tr>
<td>Working sub-directory</td>
<td>An sub-directory which can be used as an alternative for the task.</td>
</tr>
</tbody>
</table>

4. Click **Save**.

**Test result parsing:**

Bamboo supports test report in the JUnit XML format. To allow Bamboo to recognise tests from the Fastlane process you must:

1. Configure the Fastlane Scan to produce test output in the JUnit format:
   a. Create ScanFile in your Fastlane directory with the following content:

   ```
   output_types "junit"
   ```

2. Add the JUnit Parser task to parse the results and point it to the Fastlane test output directory.

**Fastlane v6.0**

This page describes how to configure a Bamboo task to use Fastlane.
To configure a Fastlane task:

1. Go to the Tasks configuration tab for the job.
2. Click the Add task button. From the list of task types, select Fastlane.
3. Provide the Fastlane settings:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tasks Description</td>
<td>A description of the task, which is displayed in Bamboo.</td>
</tr>
<tr>
<td>Disable this task</td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
<tr>
<td>Executable</td>
<td>The executable that is available to perform the task. The executable that you select will become one of the task's (and so, the job's) requirements.</td>
</tr>
<tr>
<td>Lane</td>
<td>The lane you want to execute. This field also allows you to define Fastlane properties such as param:paramValue.</td>
</tr>
<tr>
<td>Environment variables</td>
<td>Extra parameter variables. You can define multiple variables.</td>
</tr>
<tr>
<td>Working sub-directory</td>
<td>An sub-directory which can be used as an alternative for the task.</td>
</tr>
</tbody>
</table>

4. Click Save.

Test result parsing:

Bamboo supports test report in the JUnit XML format. To allow Bamboo to recognise tests from the Fastlane process you must:

1. Configure the Fastlane Scan to produce test output in the JUnit format:
   a. Create ScanFile in your Fastlane directory with the following content:

   ```
   output_types "junit"
   ```

2. Add the JUnit Parser task to parse the results and point it to the Fastlane test output directory.

**Grails**

This page describes how to configure a Bamboo Grails task.

Bamboo supports Grails versions 1.2.x, 1.3.x, and 2.x.

**Related pages:**

- Configuring tasks
- Configuring jobs
- Defining a new JDK capability

To configure a Grails task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing Grails task, or click Add Task and then Grails to create a new task.
3. Complete the following settings:

   **Task Description**
   A description of the task, which is displayed in Bamboo.

   **Disable this task**
   Check, or clear, to selectively run this task.

   **Executable**
   The Grails executable that is available to perform the task. The executable that you select will become one of the task's (and so, the job's) requirements.

   You can **add other executables**, if required.

   **Grails Commands**
   The Grails commands that you want Bamboo to execute. See the Grails Command Line Reference documentation for more details on Grails commands.
   - You can use `-D` to define one or more JVM parameters, e.g.: `-Djava.awt.headless=true` will pass the parameter
'java.awt.headless' with a value of 'true'.

- You can include variables (see Bamboo variables).

**Build JDK**

The JDKs that are available to perform the task. The JDK that you select will become one of the task's (and so, the job's) requirements. You can add other JDKs, if required.

**Environment Variables** *(Optional)*

Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Using global, plan or build-specific variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g. `ANT_OPTS=-Xms200m -Xmx700m`).

**Working Sub Directory**

An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

**The build will produce test results**

Choose one of the following: *Look in the standard test results directory* – Bamboo looks in the standard directory for the test results. Use this unless you've customized your test runner to output the results to a different location. *Specify custom results directories* – Specify the custom directory, relative to the root directory, where test results will be created. You can use Ant-style patterns such as `**/test-reports/*.xml`.

1. Bamboo requires test results to be in JUnit XML format. ! For jobs that use CVS, the root directory is `<bamboo-home>/xml-data/build-dir/JOB_KEY/<cvs-module>`.
2. **Click Save.**

### Maven v6.1

This page describes how to configure a Bamboo task to use a Maven executable. Apache Maven is a tool used for building and managing Java-based projects.

**Related pages:**
- Configuring tasks
- Configuring jobs
- Viewing a job’s Maven dependencies
- Defining a new JDK capability

**Atlassian blogs:**
- Forgetful Maven Users, Rejoice! A new Bamboo task “releases” you from worry.

**To configure a Maven task:**

1. Navigate to the **Tasks** configuration tab for the job (this will be the default)
1. Job if creating a new plan.
2. Click the name of an existing Maven task, or click **Add Task** and then a Maven option (e.g. **Maven 2.x**) to create a new task.
3. Complete the following settings:

   **Task Description**
   A description of the task, which is displayed in Bamboo.

   **Disable this task**
   Check, or clear, to selectively run this task.

   **Executable**
   The Maven executable that is available to perform the task. The executable that you select will become one of the task's (and so, the job's) requirements.

   You can **add other executables**, if required.

   **Goal**
   The Maven goal that Bamboo will execute.
   - You can use `'-D'` to define one or more JVM parameters. For example, `-Djava.awt.headless=true` will pass the parameter `java.awt.headless` with a value of `true`.
   - Multiple maven goals can be specified, separated spaces.
   - You can include variables (see Using Global or Build-specific Variables).

   **Use Maven Return Code**
   Select to have Bamboo skip log parsing.

   **Build JDK**
   The JDKs that are available to perform the task. The JDK that you select will become one of the task's (and so, the job's) requirements.

   You can **add other JDKs**, if required.

   **Override Project File** (Optional: **Maven 2.x** and later only)
   The path to your Maven project file, relative to the working sub directory specified. If this is not specified, Maven will use the pom.xml in the root of the working sub directory.

   **Environment Variables** (Optional)
   Additional system environment variables that you want to pass to your build.

   Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Using Global or Build-specific Variables).

   Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g MAVEN_OPTS="-Xms200m -Xmx700m").

   **Working Sub Directory**
   (Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory.

   This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

   **The build will produce test results**
   Choose one of the following: Look in the standard test results directory or Specify custom results directories – Specify the alternative directory, relative to the root directory, where test results will be created. You can use Ant-style patterns such as **/test-reports/**.

   1. Bamboo requires test results to be in JUnit XML format. For jobs that use CVS, the root directory is <bamboo-home>/xml-data/build-dir/JOB_KEY/<cvs-module>.

4. Click **Save**.

**MSBuild**
This page describes how to configure a Bamboo task to use an MSBuild executable.

Note that you cannot use Clover to collect code coverage for MSBuild builds, as Clover only...
To configure an MSBuild task:

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired MSBuild task, or click **Add Task** and then **MSBuild** if creating a new task.
3. Complete the following settings:

   **MSBuild configuration**

   **Task Description**
   A description of the task, which is displayed in Bamboo.

   **Executable**
   The MSBuild executable that is available to perform the task. The executable you select will become one of the task's (and so, the job's) requirements.

   You can **add other executables**, if required.

   **Project File**
   The name of the solution, project file or MSBuild project to execute, for example `ExampleSolution.sln`. You can include variables (see [Bamboo variables](#)).

   **Options**
   The MSBuild command line options that you want to include.

   By default, Bamboo 5.7 (and later versions) writes the contents of the **Projects File** and **Options** fields to an MSBuild response file. See [below](#) for more information.

   You can include variables (see [Bamboo variables](#)).

4. If required, specify environment variables and working directory settings: **Environment Variables** (Optional)

   Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see [Bamboo variables](#)).

   Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g `ANT_OPTS=-Xms200m -Xmx700m`).

   **Working Sub Directory** (Optional)

   An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

   **Run as Powershell script** (Optional, Windows only)

   Check the 'Run as Powershell script' checkbox to run the script with Powershell instead of cmd.exe which interprets .bat files. The inline editor supports Powershell syntax.

5. Click **Save**.
Passing options to MSBuild

By default, Bamboo 5.7 (and later versions) writes the contents of the Projects File and Options fields to an MSBuild response file:

```
# MSBuild response file generated by Atlassian Bamboo
%CONTENTS_OF_OPTIONS_FIELD%
%CONTENTS_OF_PROJECTS_FILE_FIELD%
```

and then runs the following command:

```
msbuild.exe @<full-path-to-response-file>response-file.rsp
```

This allows you to use the same settings with the Bamboo MSBuild task as you would use when calling MSBuild on the command line.

You can disable creation of the response file. In that case, Bamboo will create a .bat file instead:

```
"<full-path-to-msbuild>msbuild.exe" %CONTENTS_OF_OPTIONS_FIELD%
%CONTENTS_OF_PROJECTS_FILE_FIELD%
```

and run that.

Click here to see how to disable use of the response file...

To disable use of the MSBuild response file, set the bamboo.plugin.dotnet.msbuild.useResponseFile system property to false.

There are a couple of ways to do that:
If you start the Bamboo server or remote agents manually you can set the property on the command line, as an argument to the JVM, like this:

```
-Dbamboo.plugin.dotnet.msbuild.useResponseFile=false
```

Do this on all Bamboo agents, and on the Bamboo server if you use local agents.

If your agents are run as a service, set the system property in the `<Bamboo agent home directory>/conf/wrapper.conf` configuration file, like this:

```
# The Bamboo Agent home configuration file
wrapper.java.additional.1=-Dbamboo.home=/home/bamboo/bamboo-agent-home
wrapper.java.additional.2=-Dbamboo.agent.ignoreServerCertName=false
wrapper.java.additional.3=-Dbamboo.plugin.dotnet.msbuild.useResponseFile=false
```

If your Bamboo server runs as a service, add the system property to the `<Bamboo home directory>/conf/wrapper.conf` configuration file.

---

**.MSBuild v5.14**

This page describes how to configure a Bamboo task to use an MSBuild executable.

Note that you cannot use Clover to collect code coverage for MSBuild builds, as Clover only supports builders of Java/Groovy-based projects, such as Ant, Maven or Grails.

To configure an MSBuild task:

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired MSBuild task, or click **Add Task** and then **MSBuild** if creating a new task.
3. Complete the following settings:

<table>
<thead>
<tr>
<th>MSBuild configuration</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Task Description</td>
<td>A description of the task, which is displayed in Bamboo.</td>
</tr>
<tr>
<td>Executable</td>
<td>The MSBuild executable that is available to perform the task. The executable you select will become one of the task's (and so, the job's) requirements. You can <strong>add other executables</strong>, if required.</td>
</tr>
<tr>
<td>Project File</td>
<td>The name of the solution, project file or MSBuild project to execute, for example <code>ExampleSolution.sln</code>. You can include variables (see Bamboo variables).</td>
</tr>
<tr>
<td>Options</td>
<td>The MSBuild command line options that you want to include. By default, Bamboo 5.7 (and later versions) writes the contents of the <strong>Projects File</strong> and <strong>Options</strong> fields to an MSBuild response file. See <strong>below</strong> for more information. You can include variables (see Bamboo variables).</td>
</tr>
</tbody>
</table>

4. If required, specify environment variables and working directory settings: **Environment Variables** *(Optional)* Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables).
Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g. `ANT_OPTS=-Xms200m -Xmx700m`).

**Working Sub Directory** (Optional)
An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

**Run as Powershell script** (Optional, Windows only)
Check the 'Run as Powershell script' checkbox to run the script with Powershell instead of cmd.exe which interprets .bat files. The inline editor supports Powershell syntax.

5. Click **Save**.
You can disable creation of the response file. In that case, Bamboo will create a .bat file instead:

```
"<full-path-to-msbuild>msbuild.exe" %CONTENTS_OF_OPTIONS_FIELD%
%CONTENTS_OF_PROJECTS_FILE_FIELD%
```

and run that.

Click here to see how to disable use of the response file...

To disable use of the MSBuild response file, set the `bamboo.plugin.dotnet.msbuild.useResponseFile` system property to `false`.

There are a couple of ways to do that:

- If you start the Bamboo server or remote agents manually you can set the property on the command line, as an argument to the JVM, like this:

  ```
  -Dbamboo.plugin.dotnet.msbuild.useResponseFile=false
  ```

  Do this on all Bamboo agents, and on the Bamboo server if you use local agents.

- If your agents are run as a service, set the system property in the `<Bamboo agent home directory>/conf/wrapper.conf` configuration file, like this:

  ```
  # The Bamboo Agent home configuration file
  wrapper.java.additional.1=-Dbamboo.home=/home/bamboo/bamboo-agent-home
  wrapper.java.additional.2=-Dbamboo.agent.ignoreServerCertName=false
  wrapper.java.additional.3=-Dbamboo.plugin.dotnet.msbuild.useResponseFile=false
  ```

- If your Bamboo server runs as a service, add the system property to the `<Bamboo home directory>/conf/wrapper.conf` configuration file.

### MSBuild v5.15

This page describes how to configure a Bamboo task to use an MSBuild executable.

Note that you cannot use Clover to collect code coverage for MSBuild builds, as Clover only supports builders of Java/Groovy-based projects, such as Ant, Maven or Grails.

To configure an MSBuild task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired MSBuild task, or click Add Task and then MSBuild if creating a new task.
3. Complete the following settings:

<table>
<thead>
<tr>
<th>MSBuild configuration</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Task Description</strong></td>
<td>A description of the task, which is displayed in Bamboo.</td>
</tr>
<tr>
<td><strong>Executable</strong></td>
<td>The MSBuild executable that is available to perform the task. The executable you select will become one of the task’s (and so, the job's) requirements. You can add other executables, if required.</td>
</tr>
</tbody>
</table>

Related pages:

- Configuring jobs
Project File | The name of the solution, project file or MSBuild project to execute, for example ExampleSolution.sln. You can include variables (see Bamboo variables).

Options | The MSBuild command line options that you want to include. 
By default, Bamboo 5.7 (and later versions) writes the contents of the Projects File and Options fields to an MSBuild response file. See below for more information.
You can include variables (see Bamboo variables).

4. If required, specify environment variables and working directory settings: Environment Variables (Optional) 
Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables).
Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g ANT_OPTS="-Xms200m -Xmx700m").

Working Sub Directory (Optional)
An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Run as Powershell script (Optional, Windows only)
Check the 'Run as Powershell script' checkbox to run the script with Powershell instead of cmd.exe which interprets .bat files.
The inline editor supports Powershell syntax.

5. Click Save.

Passing options to MSBuild
By default, Bamboo 5.7 (and later versions) writes the contents of the Projects File and Options fields to an MSBuild response file:
and then runs the following command:

```
msbuild.exe @<full-path-to-response-file>response-file.rsp
```

This allows you to use the same settings with the Bamboo MSBuild task as you would use when calling MSBuild on the command line.

You can disable creation of the response file. In that case, Bamboo will create a .bat file instead:

```
"<full-path-to-msbuild>msbuild.exe" %CONTENTS_OF_OPTIONS_FIELD%
%CONTENTS_OF_PROJECTS_FILE_FIELD%
```

and run that.

To disable use of the MSBuild response file, set the `bamboo.plugin.dotnet.msbuild.useResponseFile` system property to false.

There are a couple of ways to do that:

- If you start the Bamboo server or remote agents manually you can set the property on the command line, as an argument to the JVM, like this:

```
-Dbamboo.plugin.dotnet.msbuild.useResponseFile=false
```

Do this on all Bamboo agents, and on the Bamboo server if you use local agents.

- If your agents are run as a service, set the system property in the `<Bamboo agent home directory>/conf/wrapper.conf` configuration file, like this:

```java
# The Bamboo Agent home configuration file
wrapper.java.additional.1=-Dbamboo.home=/home/bamboo/bamboo-agent-home
wrapper.java.additional.2=-Dbamboo.agent.ignoreServerCertName=false
wrapper.java.additional.3=-Dbamboo.plugin.dotnet.msbuild.useResponseFile=false
```

- If your Bamboo server runs as a service, add the system property to the `<Bamboo home directory>/conf/wrapper.conf` configuration file.

---

**MSBuild v6.0**

This page describes how to configure a Bamboo task to use an MSBuild executable.

Note that you cannot use Clover to collect code coverage for MSBuild builds, as Clover only supports builders of Java/Groovy-based projects, such as Ant, Maven or Grails.

This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

   Run as Powershell script (Optional, Windows only)
   Check the 'Run as Powershell script' checkbox to run the script with Powershell instead of cmd.exe which interprets .bat files. The inline editor supports Powershell syntax.

5. Click Save.
Passing options to MSBuild

By default, Bamboo 5.7 (and later versions) writes the contents of the Projects File and Options fields to an MSBuild response file:

```shell
# MSBuild response file generated by Atlassian Bamboo
%CONTENTS_OF_OPTIONS_FIELD%
%CONTENTS_OF_PROJECTS_FILE_FIELD%
```

and then runs the following command:

```shell
msbuild.exe @<full-path-to-response-file>response-file.rsp
```

This allows you to use the same settings with the Bamboo MSBuild task as you would use when calling MSBuild on the command line.

You can disable creation of the response file. In that case, Bamboo will create a .bat file instead:

```shell
"<full-path-to-msbuild>msbuild.exe" %CONTENTS_OF_OPTIONS_FIELD%
%CONTENTS_OF_PROJECTS_FILE_FIELD%
```

and run that.

Click here to see how to disable use of the response file...

To disable use of the MSBuild response file, set the `bamboo.plugin.dotnet.msbuild.useResponseFile` system property to false.

There are a couple of ways to do that:
If you start the Bamboo server or remote agents manually you can set the property on the command line, as an argument to the JVM, like this:

```
-Dbamboo.plugin.dotnet.msbuild.useResponseFile=false
```

Do this on all Bamboo agents, and on the Bamboo server if you use local agents.

If your agents are run as a service, set the system property in the `<Bamboo agent home directory>/conf/wrapper.conf` configuration file, like this:

```
# The Bamboo Agent home configuration file
wrapper.java.additional.1=-Dbamboo.home=/home/bamboo/bamboo-agent-home
wrapper.java.additional.2=-Dbamboo.agent.ignoreServerCertName=false
wrapper.java.additional.3=-Dbamboo.plugin.dotnet.msbuild.useResponseFile=false
```

If your Bamboo server runs as a service, add the system property to the `<Bamboo home directory>/conf/wrapper.conf` configuration file.

**MSBuild v6.1**

This page describes how to configure a Bamboo task to use an MSBuild executable.

Note that you cannot use Clover to collect code coverage for MSBuild builds, as Clover only supports builders of Java/Groovy-based projects, such as Ant, Maven or Grails.

To configure an MSBuild task:

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired MSBuild task, or click **Add Task** and then **MSBuild** if creating a new task.
3. Complete the following settings:

**MSBuild configuration**

**Task Description**

A description of the task, which is displayed in Bamboo.

**Executable**

The MSBuild executable that is available to perform the task. The executable you select will become one of the task's (and so, the job's) requirements.

You can add other executables, if required.

**Project File**

The name of the solution, project file or MSBuild project to execute, for example `ExampleSolution.sln`. You can include variables (see **Bamboo variables**).

**Options**

The MSBuild command line options that you want to include.

By default, Bamboo 5.7 (and later versions) writes the contents of the **Projects File** and **Options** fields to an MSBuild response file. See below for more information.

You can include variables (see **Bamboo variables**).

4. If required, specify environment variables and working directory settings: **Environment Variables** (Optional)

Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see **Bamboo variables**).
Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g. `ANT_OPTS=-Xms200m -Xmx700m`).

**Working Sub Directory** (Optional)
An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

**Run as Powershell script** (Optional, Windows only)
Check the 'Run as Powershell script' checkbox to run the script with Powershell instead of cmd.exe which interprets .bat files. The inline editor supports Powershell syntax.

5. **Click Save.**

---

**Passing options to MSBuild**

By default, Bamboo 5.7 (and later versions) writes the contents of the **Projects File** and **Options** fields to an MSBuild response file:

```
# MSBuild response file generated by Atlassian Bamboo
%CONTENTS_OF_OPTIONS_FIELD%
%CONTENTS_OF_PROJECTS_FILE_FIELD%
```

and then runs the following command:

```
msbuild.exe @<full-path-to-response-file>response-file.rsp
```

This allows you to use the same settings with the Bamboo MSBuild task as you would use when calling MSBuild on the command line.
You can disable creation of the response file. In that case, Bamboo will create a .bat file instead:

```
"<full-path-to-msbuild>msbuild.exe" %CONTENTS_OF_OPTIONS_FIELD% %CONTENTS_OF_PROJECTS_FILE_FIELD%
```

and run that.

To disable use of the MSBuild response file, set the `bamboo.plugin.dotnet.msbuild.useResponseFile` system property to false.

There are a couple of ways to do that:

- If you start the Bamboo server or remote agents manually you can set the property on the command line, as an argument to the JVM, like this:

  ```
  -Dbamboo.plugin.dotnet.msbuild.useResponseFile=false
  ```

  Do this on all Bamboo agents, and on the Bamboo server if you use local agents.

- If your agents are run as a service, set the system property in the `<Bamboo agent home directory>/conf/wrapper.conf` configuration file, like this:

  ```
  # The Bamboo Agent home configuration file
  wrapper.java.additional.1=-Dbamboo.home=/home/bamboo/bamboo-agent-home
  wrapper.java.additional.2=-Dbamboo.agent.ignoreServerCertName=false
  wrapper.java.additional.3=-Dbamboo.plugin.dotnet.msbuild.useResponseFile=false
  ```

- If your Bamboo server runs as a service, add the system property to the `<Bamboo home directory>/conf/wrapper.conf` configuration file.

NAnt

This page describes how to configure a Bamboo task to use a NAnt executable.

Related pages:
- Configuring tasks
- Configuring jobs

To configure a NAnt task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired NAnt task, or click Add Task and then NAnt if creating a new task.
3. Complete the following settings:

   **NAnt configuration**

   **Task Description**
   A description of the task, which is displayed in Bamboo.

   **Executable**
   The NAnt executable that is available to perform the task. The executable that you select will become one of the task’s (and so, the job’s) requirements.

   You can add other executables, if required.
**Build File**  
The relevant file name (e.g. default.build). You can include variables (see Bamboo variables).

**Targets**  
The NAnt target that you want Bamboo to execute, for example: run. You can also include variables (see Bamboo variables).

**Options**  
The NAnt command line options that you want to include. You can also include variables (see Bamboo variables).

4. If required, specify environment variables and working directory settings:  
**Environment Variables** (Optional)  
Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables).  
Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g ANT_OPTS="-Xms200m -Xmx700m").

**Working Sub Directory** (Optional)  
An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

**Run as Powershell script** (Optional. Windows only)  
Check the 'Run as Powershell script' checkbox to run the script with Powershell instead of cmd.exe which interprets .bat files. The inline editor supports Powershell syntax.

5. Click **Save**.

Note that you cannot use Clover to collect code coverage for NAnt builds, as Clover only supports builders of Java/Groovy-based projects, such as Ant, Maven or Grails.

5. Click **Save**.

Note that you cannot use Clover to collect code coverage for NAnt builds, as Clover only supports builders of Java/Groovy-based projects, such as Ant, Maven or Grails.

---

### NAnt v6.1

This page describes how to configure a Bamboo task to use a NAnt executable.

**Related pages:**
- Configuring tasks
- Configuring jobs
Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g ANT_OPTS="-Xms200m -Xmx700m").

Working Sub Directory (Optional)
An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Run as Powershell script (Optional, Windows only)
Check the 'Run as Powershell script' checkbox to run the script with Powershell instead of cmd.exe which interprets .bat files. The inline editor supports Powershell syntax.

5. Click Save.

Note that you cannot use Clover to collect code coverage for NAnt builds, as Clover only supports builders of Java/Groovy-based projects, such as Ant, Maven or Grails.

Script
This page describes how to configure a Bamboo task to use a script executable. You can use Bash on Linux, and batch files on Windows.

Related pages:
- Configuring tasks
- Configuring jobs

To configure a script task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired script task, or click Add Task and then Script if creating a new task.
3. Complete the following settings:

Script configuration
- Task Description
  A description of the task, which is displayed in Bamboo.

Interpreter
You can select from the following interpreters:
- Shell
- Windows PowerShell
- /bin/sh or cmd.exe

Script location
Select the location of the script file.
- File — enter the location of the file in the Script file field. This can be either relative to the repository root of the plan, or absolute. You can include variables (see Bamboo variables).
- Inline — enter the script in the Script body field.

Argument
Specify an argument to pass to the script. Arguments that contain spaces must be quoted. You can include variables (see Bamboo variables).

4. If required, specify environment variables and working directory settings:

Environment Variables (Optional)
Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables).
Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g ANT_OPTS="-Xms200m -Xmx700m").

Working Sub Directory (Optional)
An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.
5. Click **Save**.

### Script configuration

**To configure a script task:**

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired script task, or click **Add Task** and then **Script** if creating a new task.
3. Complete the following settings:

<table>
<thead>
<tr>
<th><strong>Script configuration</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Task Description</strong></td>
</tr>
<tr>
<td><strong>Interpreter</strong></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
4. If required, specify environment variables and working directory settings:

**Environment Variables**

(Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g. `ANT_OPTS=-Xms200m -Xmx700m`).

**Working Sub Directory**

(Optional) An alternative subdirectory, relative to the job’s root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job’s configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

5. Click **Save**.
1. Script v6.1

This page describes how to configure a Bamboo task to use a script executable. You can use Bash on Linux, and batch files on Windows.

**Related pages:**
- Configuring tasks
- Configuring jobs

**To configure a script task:**

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired script task, or click **Add Task** and then **Script** if creating a new task.
3. Complete the following settings:

**Task configuration**

**Task Description**
A description of the task, which is displayed in Bamboo.

**Interpreter**
You can select from the following interpreters:
- Shell
- Windows PowerShell
- /bin/sh or cmd.exe

**Script location**
Select the location of the script file.

- **File** — enter the location of the file in the Script file field. This can be either relative to the repository root of the plan, or absolute. You can include variables (see Bamboo variables).
- **Inline** — enter the script in the Script body field.

**Argument**
Specify an argument to pass to the script. Arguments that contain spaces must be quoted. You can include variables (see Bamboo variables).

4. If required, specify environment variables and working directory settings:

**Environment Variables** (Optional)
Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g. `ANT_OPTS=-Xms200m -Xmx700m`).

**Working Sub Directory** (Optional)
An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

5. Click **Save**.
This page describes how to configure a Bamboo task to use a Visual Studio (devenv.exe) executable.

To configure a Visual Studio task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired MSBuild task, or click Add Task and then Visual Studio if creating a new task.
3. Complete the following settings:

   **Visual Studio configuration**

   **Task Description**
   A description of the task, which is displayed in Bamboo.

   **Executable**
   The Visual Studio executable that is available to perform the task. The executable that you select will become one of the task's (and so, the job's) requirements.

   You can add other executables, if required.

   **Solution**
To configure a Visual Studio task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired MSBuild task, or click Add Task and then Visual Studio if creating a new task.
3. Complete the following settings:

<table>
<thead>
<tr>
<th>Visual Studio configuration</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Task Description</strong></td>
<td>A description of the task, which is displayed in Bamboo.</td>
</tr>
<tr>
<td><strong>Executable</strong></td>
<td>The Visual Studio executable that is available to perform the task. The executable that you select will become one of the task’s (and so, the job’s) requirements. You can add other executables, if required.</td>
</tr>
<tr>
<td><strong>Solution</strong></td>
<td>The name of the Visual Studio solution file that you want Bamboo to execute. For example: RegexDemo/RegexDemo.sln. You can also include variables (see Bamboo variables).</td>
</tr>
</tbody>
</table>
Options

Specify any Visual Studio command-line options that you want to include (e.g. /build Debug). You can also include variables (see Bamboo variables).

Platform

Select the platform toolset required to compile your solution. This is provided as an argument to Vcvarsall.bat (see this MSDN article for more details).

4. If required, specify environment variables and working directory settings: Environment Variables (Optional)
   Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g. ANT_OPTS=-Xms200m -Xmx700m*).

Working Sub Directory (Optional)
An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Run as Powershell script (Optional, Windows only)
Check the 'Run as Powershell script' checkbox to run the script with Powershell instead of cmd.exe which interprets .bat files. The inline editor supports Powershell syntax.

5. Click Save.

Visual Studio v6.1

This page describes how to configure a Bamboo task to use a Visual Studio (devenv.exe) executable.

Related pages:
- Configuring tasks
- Configuring jobs

To configure a Visual Studio task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of the desired MSBuild task, or click Add Task and then Visual Studio if creating a new task.
3. Complete the following settings:

Visual Studio configuration

Task Description
A description of the task, which is displayed in Bamboo.

Executable
The Visual Studio executable that is available to perform the task. The executable that you select will become one of the task's (and so, the job's) requirements.

You can add other executables, if required.

Solution
The name of the Visual Studio solution file that you want Bamboo to execute. For example: RegexDemo/RegexDemo.sln. You can also include variables (see Bamboo variables).

Options
Specify any Visual Studio command-line options that you want to include (e.g. /build Debug). You can also include variables (see Bamboo variables).

Platform
Select the platform toolset required to compile your solution. This is
provided as an argument to `Vcvarsall.bat` (see this MSDN article for more details).

4. If required, specify environment variables and working directory settings: **Environment Variables** (Optional)
   Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables).
   Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g `ANT_OPTS=-Xms200m -Xmx700m`).

   **Working Sub Directory** (Optional)
   An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

   **Run as Powershell script** (Optional, Windows only)
   Check the 'Run as Powershell script' checkbox to run the script with Powershell instead of cmd.exe which interprets .bat files. The inline editor supports Powershell syntax.

5. Click **Save**.

**Xcode**

- **Prerequisites**
- **Testing iOS applications**
  - Configuring your Xcode project automated simulator tests
  - Configuring the Xcode task for testing
- **Updating the available SDKs when Xcode is upgraded**

**Prerequisites**

- **Apple Xcode 4** – or later version
- **Certificates and provisioning profiles** – You must install all required developer certificates and provisioning profiles on every machine that Bamboo will use to run your build. See the App Distribution Guide for more information.
- **Bamboo Xcode support plugin** – The latest Xcode plugin installed in your Bamboo server.
- **ios-sim** (optional when building Mac applications) – a command line utility used to launch the iOS Simulator from the command line. If you have homebrew installed, you can install it by running `brew install ios-sim`. For other installation methods, see the [ios-sim website](https://www.trachSEL.com/).
- **CocoaPods** (optional if you do not have a Podfile in your project) – CocoaPods is the library dependency manager for Mac OS X. In order for Bamboo to install dependencies from your Podfile (if you have created one), Bamboo will need it installed on all systems where the build should run.

**Testing iOS applications**

To have tests automatically run on the iOS Simulator and reported within Bamboo you must make some changes to your Xcode project's test bundles and add the Xcode build task to your Job within Bamboo.

**Configuring your Xcode project automated simulator tests**

Without modifications, Apple does not support running unit tests in the simulator using the `xcodebuild` terminal utility which Bamboo uses to automate builds and tests.

Using ios-sim and a small modification to the `RunUnitTestTests` script phase in the test bundle its possible to overcome this limitation.
Change the content of the script to:

```bash
if [ "$RUN_UNIT_TEST_WITH_IOS_SIM" = "YES" ]; then
    test_bundle_path="$BUILT_PRODUCTS_DIR/$PRODUCT_NAME.$WRAPPER_EXTENSION"
    ios-sim launch "$(dirname "$TEST_HOST")" --setenv DYLD_INSERT_LIBRARIES="/../../Library/PrivateFrameworks/IDEBundleInjection.framework/IDEBundleInjection" --setenv XCInjectBundle="$test_bundle_path" --setenv XCInjectBundleInto="$TEST_HOST" --args -SenTest All "$test_bundle_path"
    echo "Finished running tests with ios-sim"
else
    "$(SYSTEM_DEVELOPER_DIR)/Tools/RunUnitTests"
fi
```

**Configuring the Xcode task for testing**

To configure a Xcode to test an iOS project task:

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing Xcode task, or click **Add Task** then Xcode to create a new task.
3. Complete the following settings:

   **Task Description**
   A description of the task, which is displayed in Bamboo.

   **Disable this task**
   Check, or clear, to selectively run this task.

   **Apple SDK**
   The Apple SDK to target during the build.

   **Report test results**
   Report and store any OCUnit/SenTestKit results run during the build.

   **Run tests in iOS simulator**
   Provides the RUN_UNIT_TEST_WITH_IOS_SIM variable used in the custom build phase to run the unit tests on the simulator.
Click **Save**.

### Updating the available SDKs when Xcode is upgraded

When you upgrade Xcode you may need to update Bamboo with the correct SDK information.

If you use local agents:

1. Login as an administrator
2. Go to Administration -> Server Capabilities
3. Click **Detect server capabilities**

If you are using remote agents:

1. Run `xcode-build -showsdks` from the command line
2. Login as an administrator
3. In Administration -> Agents, pick the agent you wish for the new SDK capability to be present on
4. Click **Add Capability** and pick **Xcode SDK** from the **Capability Type** field
5. Set a name for the SDK (e.g. OS X 10.9)
6. Set a SDK label (e.g. macosx10.9)

---

**Xcode v5.14**

Xcode support is undergoing testing and as such is unsupported by Atlassian at this time. If you would like to see it officially supported, please vote for this [improvement request](https://jira.atlassian.com/browse/BAM-22676)
Prerequisites

- **Apple Xcode 4** – or later version
- **Certificates and provisioning profiles** – You must install all required developer certificates and provisioning profiles on every machine that Bamboo will use to run your build. See the App Distribution Guide for more information.
- **Bamboo Xcode support plugin** – The latest Xcode plugin installed in your Bamboo server.
- **Ios-sim** (optional when building Mac applications) – a command line utility used to launch the iOS Simulator from the command line. If you have homebrew installed, you can install it by running `brew install ios-sim`. For other installation methods, see the [ios-sim](https://github.com/bugs/ios-sim) website.
- **Cocoapods** (optional if you do not have a Podfile in your project) – Cocoapods is the library dependency manager for Mac OS X. In order for Bamboo to install dependencies from your Podfile (if you have created one), Bamboo will need it installed on all systems where the build should run.

Testing iOS applications

To have tests automatically run on the iOS Simulator and reported within Bamboo you must make some changes to your Xcode project's test bundles and add the Xcode build task to your Job within Bamboo.

Configuring your Xcode project automated simulator tests

Without modifications, Apple does not support running unit tests in the simulator using the `xcodebuild` terminal utility which Bamboo uses to automate builds and tests.

Using ios-sim and a small modification to the RunUnitTests script phase in the test bundle its possible to overcome this limitation.

Change the content of the script to:

```bash
# Run the unit tests in this test bundle.
"$(SYSTEM_DEVELOPER_DIR)/Tools/RunUnitTests"
```
if [ "$RUN_UNIT_TEST_WITH_IOS_SIM" = "YES" ]; then
test_bundle_path="$BUILT_PRODUCTS_DIR/$PRODUCT_NAME.$WRAPPER_EXTENSION"
ios-sim launch "$(dirname "$TEST_HOST")" --setenv
DYLD_INSERT_LIBRARIES=../../Library/PrivateFrameworks/IDEBundleInjection
framework/IDEBundleInjection --setenv
XCInjectBundle="$test_bundle_path" --setenv
XCInjectBundleInto="$TEST_HOST" --args -SenTest All "$test_bundle_path"
else
"$(SYSTEM_DEVELOPER_DIR)/Tools/RunUnitTests"
fi

Configuring the Xcode task for testing

To configure a Xcode to test an iOS project task:

1. Navigate to the Tasks configuration tab for the job (this will be the default
   job if creating a new plan).
2. Click the name of an existing Xcode task, or click Add Task then Xcode to
   create a new task.
3. Complete the following settings:

<table>
<thead>
<tr>
<th>Task Description</th>
<th>A description of the task, which is displayed in Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable this task</td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
<tr>
<td>Apple SDK</td>
<td>The Apple SDK to target during the build.</td>
</tr>
<tr>
<td>Report test results</td>
<td>Report and store any OCUnit/SenTestKit results run</td>
</tr>
<tr>
<td>Run tests in iOS simulator</td>
<td>Provides the RUN_UNIT_TEST_WITH_IOS_SIM variable used</td>
</tr>
<tr>
<td></td>
<td>in the custom build phase to run the unit tests on the</td>
</tr>
<tr>
<td></td>
<td>simulator.</td>
</tr>
</tbody>
</table>

4. Click Save.

Updating the available SDKs when Xcode is upgraded

When you upgrade Xcode you may need to update Bamboo with the correct SDK information.

If you use local agents:

1. Login as an administrator
2. Go to Administration -> Server Capabilities
3. Click Detect server capabilities

If you are using remote agents:

1. Run xcode-build -showsdks from the command line
2. Login as an administrator
3. In Administration -> Agents, pick the agent you wish for the new SDK capability to be present on
4. Click Add Capability and pick Xcode SDK from the Capability Type field
5. Set a name for the SDK (e.g. OS X 10.9)
6. Set a SDK label (e.g. macOSx10.9)

Testing iOS applications

Prerequisites

- **Apple Xcode 4** – or later version
- **Certificates and provisioning profiles** – You must install all required developer certificates and provisioning profiles on every machine that Bamboo will use to run your build. See the App Distribution Guide for more information.
- **Bamboo Xcode support plugin** – The latest Xcode plugin installed in your Bamboo server.
- **ios-sim** *(optional when building Mac applications)* – a command line utility used to launch the iOS Simulator from the command line. If you have homebrew installed, you can install it by running `brew install ios-sim`. For other installation methods, see the [ios-sim](https://github.com/lostech/ios-sim) website.
- **Cocoapods** *(optional if you do not have a Podfile in your project)* – Cocoapods is the library dependency manager for Mac OS X. In order for Bamboo to install dependencies from your Podfile (if you have created one), Bamboo will need it installed on all systems where the build should run.

Testing iOS applications
To have tests automatically run on the iOS Simulator and reported within Bamboo you must make some changes to your Xcode project’s test bundles and add the Xcode build task to your Job within Bamboo.

Configuring your Xcode project automated simulator tests

Without modifications, Apple does not support running unit tests in the simulator using the `xcodebuild` terminal utility which Bamboo uses to automate builds and tests.

Using ios-sim and a small modification to the RunUnitTests script phase in the test bundle its possible to overcome this limitation.

### Change the content of the script to:

```bash
if [ "$RUN_UNIT_TEST_WITH_IOS_SIM" = "YES" ]; then
  test_bundle_path="$BUILT_PRODUCTS_DIR/$PRODUCT_NAME.$WRAPPER_EXTENSION"
  ios-sim launch "$BUILT_PRODUCTS_DIR/$PRODUCT_NAME.$WRAPPER_EXTENSION" --setenv
  DYLD_INSERT_LIBRARIES=./Library/PrivateFrameworks/IDEBundleInjection.framework/IDEBundleInjection --setenv
  XCInjectBundle="$test_bundle_path" --setenv
  XCInjectBundleInto="$BUILT_PRODUCTS_DIR/$TEST_HOST" --args -SenTest All "$test_bundle_path"
  echo "Finished running tests with ios-sim"
else
  ""$(SYSTEM DEVELOPER_DIR)/Tools/RunUnitTests"
fi
```

### Configuring the Xcode task for testing

To configure a Xcode to test an iOS project task:

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing Xcode task, or click **Add Task** then Xcode to create a new task.
3. Complete the following settings:

<table>
<thead>
<tr>
<th>Task Description</th>

   ![Command Line Output]

2. Login as an administrator
3. In Administration -> Agents, pick the agent you wish for the new SDK capability to be present on
4. Click **Add Capability** and pick **Xcode SDK** from the **Capability Type** field
5. Set a name for the SDK (e.g. OS X 10.9)
6. Set a SDK label (e.g. macosx10.9)
Prerequisites

- Apple Xcode 4 – or later version
- Certificates and provisioning profiles – You must install all required developer certificates and provisioning profiles on every machine that Bamboo will use to run your build. See the App Distribution Guide for more information.
- Bamboo Xcode support plugin – The latest Xcode plugin installed in your Bamboo server.
- ios-sim (optional when building Mac applications) – a command line utility used to launch the iOS Simulator from the command line. If you have homebrew installed, you can install it by running `brew install ios-sim`. For other installation methods, see the ios-sim website.
- Cocoapods (optional if you do not have a Podfile in your project) – Cocoapods is the library dependency manager for Mac OS X. In order for Bamboo to install dependencies from your Podfile (if you have created one), Bamboo will need it installed on all systems where the build should run.

Testing iOS applications

To have tests automatically run on the iOS Simulator and reported within Bamboo you must make some changes to your Xcode project’s test bundles and add the Xcode build task to your Job within Bamboo.

Configuring your Xcode project automated simulator tests

Without modifications, Apple does not support running unit tests in the simulator using the `xcodebuild` terminal utility which Bamboo uses to automate builds and tests.

Using ios-sim and a small modification to the RunUnitTests script phase in the test bundle its possible to overcome this limitation.
Change the content of the script to:

```bash
if [ "$RUN_UNIT_TEST_WITH_IOS_SIM" = "YES" ]; then
  test_bundle_path="${BUILT_PRODUCTS_DIR}/${PRODUCT_NAME}.${WRAPPER_EXTENSION}"
  ios-sim launch 
  $(dirname "$TEST_HOST") --setenv DYLD_INSERT_LIBRARIES=/../../Library/PrivateFrameworks/IDEBundleInjection.framework/IDEBundleInjection --setenv XCInjectBundle="$test_bundle_path" --setenv XCInjectBundleInto="$TEST_HOST" --args -SenTest All "$test_bundle_path"
  echo "Finished running tests with ios-sim"
else
  "${SYSTEM_DEVELOPER_DIR}/Tools/RunUnitTests"
fi
```

Configuring the Xcode task for testing

To configure an Xcode task for testing an iOS project:

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing Xcode task, or click **Add Task** to create a new task.
3. Complete the following settings:

   - **Task Description**
     A description of the task, which is displayed in Bamboo.

   - **Enable this task**
     Check, or clear, to selectively run this task.

   - **Apple SDK**
     The Apple SDK to target during the build.

   - **Report test results**
     Report and store any OCUnit/SenTestKit results run during the build.

   - **Run tests in iOS simulator**
     Provides the **RUN_UNIT_TEST_WITH_IOS_SIM** variable used in the custom build phase to run the unit tests on the simulator.
4. Click **Save**.

*Updating the available SDKs when Xcode is upgraded*

When you upgrade Xcode you may need to update Bamboo with the correct SDK information.

If you use local agents:

1. Login as an administrator
2. Go to Administration -> Server Capabilities
3. Click **Detect server capabilities**

If you are using remote agents:

1. Run `xcode-build -showsdks` from the command line

   ![Xcode SDKs](image)

2. Login as an administrator
3. In Administration -> Agents, pick the agent you wish for the new SDK capability to be present on
4. Click **Add Capability** and pick **Xcode SDK** from the **Capability Type** field
5. Set a name for the SDK (e.g. OS X 10.9)
6. Set a SDK label (e.g. macosx10.9)

*Configuring a test task*

Test tasks in Bamboo parse test data, and may run tests, using a particular testing framework.

Please note:

- Java builder tasks in Bamboo (e.g. Maven) parse test information as part of the task. You do not need to configure a test task, if you have specified that test results will be produced as part of the builder task. However, you can configure a builder task to not produce test results and use a test task to parse the test data instead. For example, you may want to set up one JUnit Parser task to parse...
test data for a number of Maven tasks after they have executed.

- .Net builder tasks in Bamboo (e.g. NAnt) do not parse test information as part of the task. You must configure a test task (e.g. NUnit Parser), if you want test results from the builder task to be parsed.

**Related pages:**

- Configuring a builder task

See the following pages for more information on configuring specific test tasks:

- JUnit Parser
- MBUnit Parser
- MSTest Parser
- MSTest Runner
- NUnit Parser
- NUnit Runner
- PHPUnit
- TestNG

**Community test task plugins**

There are numerous test task plugins available on the Atlassian Marketplace. These plugins are unsupported by Atlassian for the time being but the source code has been made freely available.

<table>

**JUnit Parser**

This page describes how to configure a Bamboo task to parse JUnit test results.

Because TestNG uses the JUnit XML format, the JUnit Parser task is also able to parse TestNG test results.

Before you begin:

- Java builder tasks in Bamboo (e.g. Maven) parse test information as part of the task. You do not need to configure a test task, if you have specified that test results will be produced as part of the builder task.

**Related pages:**

- Configuring tasks
- Configuring jobs
- Configuring a test task

**Atlassian blogs:**

- So you want to run tests in parallel... now what?

**To configure a JUnit Parser task:**

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing JUnit Parser task, or click **Add Task** and then **JUnit Parser** to create a new task.
3. Update the task settings:

   **Task Description**

   Enter a description of the task, for display in Bamboo.
**JUnit Parser v5.14**

This page describes how to configure a Bamboo task to parse JUnit test results.

Because TestNG uses the JUnit XML format, the JUnit Parser task is also able to parse TestNG test results.

Before you begin:

- Java builder tasks in Bamboo (e.g. Maven) parse test information as part of the task. You do not need to configure a test task, if you have specified that test results will be produced as part of the builder task.

**Related pages:**
- Configuring tasks
- Configuring jobs
- Configuring a test task

**Atlassian blogs:**
- So you want to run tests in parallel... now what?

**To configure a JUnit Parser task:**
1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing JUnit Parser task, or click **Add Task** and then **JUnit Parser** to create a new task.
3. Update the task settings:

<table>
<thead>
<tr>
<th><strong>Task Description</strong></th>
<th>Enter a description of the task, for display in Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Disable this task</strong></td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
<tr>
<td><strong>Specify custom results directories</strong></td>
<td>Enter the name of the test results directory (or multiple directories, separated by commas). You can also use Ant-style patterns such as <code>**/test-reports/*.xml/</code> where the base directory is the &quot;working directory&quot; – this can be found at the start of your build log. Do not specify an absolute path. For jobs that use CVS, the job build's root directory is <code>&lt;bamboo-home&gt;/xml-data/build-dir/JOB_KEY/&lt;cvs-module&gt;</code>.</td>
</tr>
</tbody>
</table>

4. Click **Save**.

**JUnit Parser v6.1**

This page describes how to configure a Bamboo task to parse JUnit test results.

Because TestNG uses the JUnit XML format, the JUnit Parser task is also able to parse TestNG test results.

Before you begin:

- Java builder tasks in Bamboo (e.g. Maven) parse test information as part of the task. You do not need to configure a test task, if you have specified that test results will be produced as part of the builder task.

**Related pages:**
- Configuring tasks
- Configuring jobs
- Configuring a test task
To configure a JUnit Parser task:
1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing JUnit Parser task, or click Add Task and then JUnit Parser to create a new task.
3. Update the task settings:
   - **Task Description**: Enter a description of the task, for display in Bamboo.
   - **Disable this task**: Check, or clear, to selectively run this task.
   - **Specify custom results directories**: Enter the name of the test results directory (or multiple directories, separated by commas). You can also use Ant-style patterns such as \*/test-reports/*.xml/ where the base directory is the "working directory" – this can be found at the start of your build log. Do not specify an absolute path.
   - **MBUnit Test Results File**: Enter the name of the test results file. The test file must be in MBUnit XML format. For more information on MBUnit, see [http://www.mbunit.com/](http://www.mbunit.com/).
4. Click Save.

MBUnit Parser

This page describes how to configure a Bamboo task to parse MBUnit test results.

Before you begin:
- .NET builder tasks in Bamboo (e.g. NAnt) do not parse test information as part of the task. You must configure a test task (e.g. MBUnit Parser), if you want test results from the builder task to be parsed.

To configure a MBUnit Parser task:
1. Navigate to the Tasks configuration tab (this will be the default job if creating a new plan).
2. Click the name of an existing MBUnit Parser task, or click Add Task and then MBUnit Parser to create a new task.
3. Update the task settings:
   - **MBUnit Test Results File**: Enter the name of the test results file. The test file must be in MBUnit XML format. For more information on MBUnit, see [http://www.mbunit.com/](http://www.mbunit.com/).
4. Click Save.

**.MBUnit Parser v5.14**

This page describes how to configure a Bamboo task to parse MBUnit test results.

Before you begin:
- .NET builder tasks in Bamboo (e.g. NAnt) do not parse test information as part of the task. You must configure a test task (e.g. MBUnit Parser), if you want test results from the builder task to be parsed.

To configure a MBUnit Parser task:
1. Navigate to the Tasks configuration tab (this will be the default job if creating a new plan).
2. Click the name of an existing MBUnit Parser task, or click Add Task and then MBUnit Parser to create a new task.
3. Update the task settings:
Task Description
Enter a description of the task, for display in Bamboo.

Disable this task
Check, or clear, to selectively run this task.

MBUnit Test Results File
Enter the name of the test results file. The test file must be in MBUnit XML format. For more information on MBUnit, see http://www.mbunit.com/.

4. Click Save.

**MBUnit Parser v6.1**

This page describes how to configure a Bamboo task to parse MBUnit test results.

**Before you begin:**

- .NET builder tasks in Bamboo (e.g. NAnt) do not parse test information as part of the task. You must configure a test task (e.g. MBUnit Parser), if you want test results from the builder task to be parsed.

**Related pages:**

- Configuring a test task

**To configure a MBUnit Parser task:**

1. Navigate to the Tasks configuration tab (this will be the default job if creating a new plan).
2. Click the name of an existing MBUnit Parser task, or click Add Task and then MBUnit Parser to create a new task.
3. Update the task settings:

   **Task Description**
   Enter a description of the task, for display in Bamboo.

   **Disable this task**
   Check, or clear, to selectively run this task.

   **MBUnit Test Results File**
   Enter the name of the test results file. The test file must be in MBUnit XML format. For more information on MBUnit, see http://www.mbunit.com/.
   4. Click Save.

**MSTest Parser**

This page describes how to configure a Bamboo task to parse MSTest results.

.NET builder tasks in Bamboo (for example NAnt) do not parse test information as part of the task. To have the test results parsed, you need to configure a test task such as MSTest Parser.

**Note that each test results file must have a unique name. You can use Bamboo variables to achieve this. Here is a customer-supplied example that includes the revision and build numbers in the name of the test file:**

```
<Project-Test-Subfolder>\TestResults\<Project>TestResults-Rev_${bamboo.repository.revision.number}-Build_${bamboo.buildNumber}.trx
```

**Related pages:**

- Configuring tasks
- Configuring jobs
- Configuring a test task

**To configure a MSTest Parser task:**

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing MSTest Parser task, or click Add Task and then MSTest Parser to create a new task.
3. Update the task settings:

   **Task Description**
   Enter a description of the task, for display in Bamboo.

   **Disable this task**
   Check, or clear, to selectively run this task.
MSTest Test Results File
Enter the name of the test results file. The test file must be in MSTest format. For more information on MSTest, see this MSDN page.

4. Click Save.

.MSTest Parser v5.14
This page describes how to configure a Bamboo task to parse MSTest results.

.NET builder tasks in Bamboo (for example NAnt) do not parse test information as part of the task. To have the test results parsed, you need to configure a test task such as MSTest Parser.

Note that each test results file must have a unique name. You can use Bamboo variables to achieve this. Here is a customer-supplied example that includes the revision and build numbers in the name of the test file:

```
<Project-Test-Subfolder>\TestResults\<Project>TestResults-Rev_${bamboo.repository.revision.number}-Build_${bamboo.buildNumber}.trx
```

- Configuring a test task

To configure a MSTest Parser task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing MSTest Parser task, or click Add Task and then MSTest Parser to create a new task.
3. Update the task settings:

<table>
<thead>
<tr>
<th>Task Description</th>
<th>Enter a description of the task, for display in Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable this task</td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
<tr>
<td>MSTest Test Results File</td>
<td>Enter the name of the test results file. The test file must be in MSTest format. For more information on MSTest, see this MSDN page.</td>
</tr>
</tbody>
</table>
Enter a description of the task, for display in Bamboo.

**Disable this task**
Check, or clear, to selectively run this task.

**MSTest Test Results File**
Enter the name of the test results file. The test file must be in MSTest format. For more information on MSTest, see [this MSDN page](#).

4. Click **Save**.

**MSTest Runner**
This page describes how to configure a Bamboo MSTest Runner task. The MSTest Runner task runs and parses tests for .NET builds.

Before you begin:

- .NET builder tasks in Bamboo (e.g. NAnt) do not parse test information as part of the task. You must configure a test task (e.g. MSTest Parser), if you want test results from the builder task to be parsed.

- If Bamboo is running as a Windows service, ensure that the Service is running as a local user instead of a System User (Bamboo will install itself as the SYSTEM user on Windows).

To configure a Bamboo MSTest Runner task:

1. Navigate to the **Tasks** configuration tab for the job (this will be the default Job if creating a new plan).
2. Click the name of an existing MSTest Runner task, or click **Add Task** and then MSTest Runner to create a new task.
3. Update the task settings:

   **Related pages:**
   - Configuring tasks
   - Configuring jobs
   - Configuring a test task

**Task Description**
A description of the task, for display in Bamboo.

**Disable this task**
Check, or clear, to selectively run this task.

**Executable**
The MSTest Runner executable that you wish to use for this task (e.g. "Visual Studio 2010"). The executable that you select will become one of the task's capability requirements (and hence, one of the job's requirements). For details, please see [Configuring a job's requirements](#).

Specifically for MSTest, we recommend that the executable be defined with the Visual Studio IDE folder path. Example:

```
C:\Program Files (x86)\Microsoft Visual Studio 10.0\Common7\IDE
```

This will allow Bamboo to find the necessary resources.

**Environment Variables**
Any extra environment variables you want to pass to your build. e.g. JAVA_OPTS="-Xmx256m -Xms128m".

**Container**
The test container, i.e. the file that contains the tests you want to run. For example, tests.dll. The value of this field is passed to the MSTest.exe as the /testcontainer parameter. See MSTest.exe Command-Line Options (MSDN).

**Test Metadata**
The path to the Test Metadata file relative to the working directory. For example, "MyApp\MyApp.vsmdi"

**Result Filename**
The file that you want to save the test results to. For example, testResults.trx. The value of this field is passed to the MSTest.exe as the /resultsfile parameter. See MSTest.exe Command-Line Options (MSDN).

**Run Configuration**
The run configuration that you want to use. For example, localtestrun.Testrunconfig. The value of this field is passed to the MSTest.exe as the /runconfig parameter. See MSTest.exe Command-Line Options (MSDN).
### MSTest Runner v5.14

This page describes how to configure a Bamboo MSTest Runner task. The MSTest Runner task runs and parses tests for .NET builds.

### Before you begin:

- .NET builder tasks in Bamboo (e.g. NAnt) do not parse test information as part of the task. You must configure a test task (e.g. MSTest Parser), if you want test results from the builder task to be parsed.
- If Bamboo is running as a Windows service, ensure that the Service is running as a local user instead of a System User (Bamboo will install itself as the SYSTEM user on Windows).

### To configure a Bamboo MSTest Runner task:

1. Navigate to the Tasks configuration tab for the job (this will be the default Job if creating a new plan).
2. Click the name of an existing MSTest Runner task, or click Add Task and then MSTest Runner to create a new task.
3. Update the task settings:

<table>
<thead>
<tr>
<th>Task Description</th>
<th>A description of the task, for display in Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable this task</td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
<tr>
<td>Executable</td>
<td>The MSTest Runner executable that you wish to use for this task (e.g., &quot;Visual Studio 2010&quot;). The executable that you select will become one of the task's capability requirements (and hence, one of the job's requirements). For details, please see Configuring a job's requirements.</td>
</tr>
<tr>
<td>Environment Variables</td>
<td>Any extra environment variables you want to pass to your build. e.g. JAVA_OPTS=&quot;-Xmx256m -Xms128m&quot;.</td>
</tr>
<tr>
<td>Container</td>
<td>The test container, i.e. the file that contains the tests you want to run. For example, tests.dll. The value of this field is passed to the MSTest.exe as the /testcontainer parameter. See MSTest.exe Command-Line Options (MSDN).</td>
</tr>
<tr>

</tr>
<tr>
<td>Run Configuration</td>
<td>The run configuration that you want to use. For example, local\testrun.Testrunconfig. The value of this field is passed to the MSTest.exe as the /runconfig parameter. See MSTest.exe Command-Line Options (MSDN).</td>
</tr>
</tbody>
</table>

### MSTest Runner v6.1

This page describes how to configure a Bamboo MSTest Runner task. The MSTest Runner task runs and parses tests for .NET builds.

### Before you begin:

Specifically for MSTest, we recommend that the executable be defined with the Visual Studio IDE folder path. Example:

```
C:\Program Files (x86)\Microsoft Visual Studio 10.0\Common7\IDE\
```

This will allow Bamboo to find the necessary resources.

PHPUnit

This page describes how to configure a PHPUnit task.

Before you begin:

- To use this task, you will need to install PHPUnit and reference the path to your PHP command-line interpreter, (e.g. /usr/bin/php on Ubuntu).

Related pages:
- Configuring tasks
- Configuring jobs

To configure a PHPUnit task:
1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing task, or click **Add Task** and then **PHPUnit** (or another option, such as **PHPUnit 3.3.X**) to create a new task.

3. Update the task settings:

   **Task Description**
   Enter a description of the task, for display in Bamboo.

   **Disable this task**
   Check, or clear, to selectively run this task.

   **Executable**
   Select the PHPUnit executable that you wish to configure for this task (e.g. "PHPUnit 3.3.x" or "PHPUnit"). The executable that you select will become one of the task's capability requirements (and hence, one of the job's requirements). For details, please see **Configuring a job's requirements**.

   **Arguments**
   Type the name of the directory/files that will be analyzed recursively by PHPUnit. The default value is "." (i.e. the working subdirectory, if specified). You must specify at least one argument.

   **Environment Variables** (Optional)
   Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see **Using global, plan or build-specific variables**). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g. `ANT_OPTS="-Xms200m -Xmx700m"`).

   **Working Sub Directory** (Optional)
   An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

   **Log test execution to XML file**
   Select if you want PHPUnit to record test results in JUnit format. This format is also used by TestNG.
   **Test Result File** — the relative location, and name, of the file to record PHPUnit test results.

   **Generate code coverage report in HTML format**
   Select if you want PHPUnit to generate code coverage data in HTML format (e.g. for PHPUnit HTML Code Coverage reports).
   **HTML Code Coverage Directory** — the relative location of the directory to store the code coverage report.

4. Click **Save**.
To configure a PHPUnit task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing task, or click Add Task and then PHPUnit (or another option, such as PHPUnit 3.3.X) to create a new task.
3. Update the task settings:
<table>
<thead>
<tr>
<th><strong>Task Description</strong></th>
<th>Enter a description of the task, for display in Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Disable this task</strong></td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
<tr>
<td><strong>Executable</strong></td>
<td>Select the PHPUnit executable that you wish to configure for this task (e.g. &quot;PHPUnit 3.3.x&quot; or &quot;PHPUnit&quot;). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g ANT_OPTS="-Xms200m -Xmx700m").

Working Sub Directory (Optional)
An alternative subdirectory, relative to the job’s root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job’s configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Log test execution to XML file
Select if you want PHPUnit to record test results in JUnit format. This format is also used by TestNG.
Test Result File — the relative location, and name, of the file to record PHPUnit test results.

Generate code coverage report in HTML format
Select if you want PHPUnit to generate code coverage data in HTML format (e.g. for PHPUnit HTML Code Coverage reports).
HTML Code Coverage Directory — the relative location of the directory to store the code coverage report.

4. Click Save.
TestNG

This page describes how to configure a Bamboo task to parse TestNG test results.

Before you begin:

- Java builder tasks in Bamboo (e.g. Maven) parse test information as part of the task. You do not need to configure a test task, if you have specified that test results will be produced as part of the builder task.

To configure a TestNG Parser task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing TestNG task, or click Add Task and then TestNG to create a new task.
3. Update the task settings:

   - **Task Description**
     Enter a description of the task, for display in Bamboo.

   - **Disable this task**
     Check, or clear, to selectively run this task.
**Specify custom results directories**
Enter the name of the test results directory (or multiple directories, separated by commas). You can also use Ant-style patterns such as `*/test-reports/.xml`. Please specify file path relative to your job build's root directory. Do not specify an absolute path. For jobs that use CVS, the job build's root directory is `<bamboo-home>/xml-data/build-dir/JOB_KEY/<cvs-module>`.

4. Click **Save**.

**.TestNG v5.14**

This page describes how to configure a Bamboo task to parse TestNG test results.

Before you begin:

- Java builder tasks in Bamboo (e.g. Maven) parse test information as part of the task. You do not need to configure a test task, if you have specified that test results will be produced as part of the builder task.

To configure a TestNG Parser task:

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing TestNG task, or click **Add Task** and then **TestNG** to create a new task.
3. Update the task settings:

<table>
<thead>
<tr>
<th>Task Description</th>
<th>Enter a description of the task, for display in Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable this task</td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
</tbody>
</table>
| Specify custom results directories | Enter the name of the test results directory (or multiple directories, separated by commas). You can also use Ant-style patterns such as `*/test-reports/.xml`. Please specify file path relative to your job build's root directory. Do not specify an absolute path. For jobs that use CVS, the job build's root directory is `<bamboo-home>/xml-data/build-dir/JOB_KEY/<cvs-module>`.

4. Click **Save**.

**.TestNG v6.1**

This page describes how to configure a Bamboo task to parse TestNG test results.

Before you begin:

- Java builder tasks in Bamboo (e.g. Maven) parse test information as part of the task. You do not need to configure a test task, if you have specified that test results will be produced as part of the builder task.

To configure a TestNG Parser task:

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing TestNG task, or click **Add Task** and then **TestNG** to create a new task.
3. Update the task settings:

```markdown
<table>
<thead>
<tr>
<th>Task Description</th>
<th>Enter a description of the task, for display in Bamboo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable this task</td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
</tbody>
</table>
| Specify custom results directories | Enter the name of the test results directory (or multiple directories, separated by commas). You can also use Ant-style patterns such as `*/test-reports/.xml`. Please specify file path relative to your job build's root directory. Do not specify an absolute path. For jobs that use CVS, the job build's root directory is `<bamboo-home>/xml-data/build-dir/JOB_KEY/<cvs-module>`.
```
4. Click **Save**.

**Configuring a variables task**

Variables tasks in Bamboo allow you to:

- pass a value between stages.
- pass a value from a plan to a deployment project.
- read variables from a file using a 'key=value' format.
- print to file the current values of the available variables in your build.

**Inject Bamboo variables task**

The 'Inject Bamboo variables' task allows you to read the values for variables from a file, and create those variables in your build plan.

The file should use a 'key=value' format.

You can choose if those variables should have local scope (in which case they cease to exist when the job finishes) or result scope (in which case they are persisted and passed into subsequent stages or related deployment releases).

See [Configuring tasks](#) for help on creating a task.

**Dump variables to log task**

The 'Dump variables to log' task simply writes out the current values of all variables used in the build.

See [Configuring tasks](#) for help on creating a task.

**FAQ**

Q. What happens if the same key is used twice?
A. The last assignment will prevail. If you set the scope to local variable with the same key as an existing result variable, the value of the result variable will be restored when the job finishes.

Q. What if I manually set a variable with the same key as a result variable?

A. Same as above – the last assignment wins.

Q. Can I manually override a result variable in a subsequent manual stage?

A. Yes.

Q. What if 2 jobs in the same stage create the same variable?

A. The variable will exist but it is undefined which value will ultimately be assigned to it.

Q. Is restarting builds, re-running failed jobs or continuing from a manual stage supported?

A. Of course! One caveat though: if you restart a build which has an associated deployment release, the variable in the release will not be refreshed. We’re working on that...

Configuring a variables task v5.14

Variables tasks in Bamboo allow you to:

- pass a value between stages.
- pass a value from a plan to a deployment project.
- read variables from a file using a ‘key=value’ format.
- print to file the current values of the available variables in your build.

Inject Bamboo variables task

The 'Inject Bamboo variables' task allows you to read the values for variables from a file, and create those variables in your build plan.

The file should use a ‘key=value’ format. Note that starting from Bamboo version 5.14, you must provide relative paths to the property file.

You can choose if those variables should have a local scope (in which case they cease to exist when the job finishes) or result scope (in which case they are persisted and passed into subsequent stages or related deployment releases).

See Configuring tasks for help in creating a task.

Dump variables to log task

The 'Dump variables to log' task simply writes out the current values of all variables used in the build.

See Configuring tasks for help on creating a task.

Configuring a deployment task

Deployment tasks in Bamboo allow you to set up plans that can manage the continuous deployment and delivery of your application.

See the following pages for more information on configuring specific deployment tasks in Bamboo:

- Using Tomcat with Bamboo for continuous deployment
- Using the SCP task in Bamboo
- Using the SSH task in Bamboo
- Using the Heroku task in Bamboo
- Using the AWS CodeDeploy task

Using the SCP task in Bamboo

You can use the Bamboo SCP task to upload files from Bamboo directly to a remote server as part of a Bamboo job. The SCP task is able to copy multiple files and preserves the directory structure for the copied files.

See Configuring a deployment task for an overview of Bamboo deployment tasks.

To configure an SCP task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing SCP task, or click Add Task and then SCP Task to create a new task.
3. Complete the following settings:

   **Task Description**
   Helps you identify the purpose of the task.

   **Disable this task**
   Check, or clear, to selectively run this task.

   **Host**
   The hostname or IP address of the remote server to which the files will be copied.

   **Verify remote host fingerprint on connect**
Enter the host fingerprint to be verified. See below for more details.

**Port**
The port number of the remote host that is used for the SSH connection.
The default value is 22.

**Username**
The username to use to connect to the remote host.

**Authentication Type**
- **Password** – the password associated with Username.
- **Key without passphrase** – browse to the SSH private key with which to authenticate with the remote host.
- **Key with passphrase** – browse to the SSH private key, and supply the passphrase, to use to authenticate with the remote host.

**Local Path**
The local path (relative to the Bamboo working directory) to the files you want to copy. Use commas to separate files and directories. You can also use Ant-style pattern matching to include multiple files, such as `/**/*.jar`.

**Remote Path**
The path to the destination directory on the remote server.

4. Click **Save**.
Host fingerprint

You can determine the fingerprint for a host by running:

```
ssh-keygen -l -F <HOSTNAME>
```

The fingerprint is the part of the response shown in the screenshot below:
Using the SCP task in Bamboo v5.14

You can use the Bamboo SCP task to upload files from Bamboo directly to a remote server as part of a Bamboo job. The SCP task is able to copy multiple files and preserves the directory structure for the copied files.

See Configuring a deployment task for an overview of Bamboo deployment tasks.

To configure an SCP task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing SCP task, or click Add Task and then SCP Task to create a new task.
3. Complete the following settings:

<table>
<thead>
<tr>
<th>Task Description</th>
<th>Helps you identify the purpose of the task.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable this task</td>
<td>Check, or clear, to selectively run this task.</td>

Host fingerprint
You can determine the fingerprint for a host by running:
Using the SCP task in Bamboo v6.1

You can use the Bamboo SCP task to upload files from Bamboo directly to a remote server as part of a Bamboo job. The SCP task is able to copy multiple files and preserves the directory structure for the copied files.

See Configuring a deployment task for an overview of Bamboo deployment tasks.

To configure an SCP task:

1. Navigate to the Tasks configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing SCP task, or click Add Task and then SCP Task to create a new task.
3. Complete the following settings:

   **Task Description**
   Helps you identify the purpose of the task.

   **Disable this task**
   Check, or clear, to selectively run this task.

   **Host**
   The hostname or IP address of the remote server to which the files will be copied.

   **Verify remote host fingerprint on connect**
   Enter the host fingerprint to be verified. See below for more details.

   **Port**
   The port number of the remote host that is used for the SSH connection. The default value is 22.

   **Username**
   The username to use to connect to the remote host.

   **Authentication Type**
   - **Password** – the password associated with Username.
   - **Key without passphrase** – browse to the SSH private key with which to authenticate with the remote host.
   - **Key with passphrase** – browse to the SSH private key, and supply the passphrase, to use to authenticate with the remote host.

   **Local Path**
   The local path (relative to the Bamboo working directory) to the files you want to copy. Use commas to separate files and directories. You can also use Ant-style pattern matching to include multiple files, such as */target/*.jar.

   **Remote Path**
   The path to the destination directory on the remote server.

4. Click Save.
Host fingerprint

You can determine the fingerprint for a host by running:

```
ssh-keygen -l -F <HOSTNAME>
```

The fingerprint is the part of the response shown in the screenshot below:
Using the SSH task in Bamboo

You can use the Bamboo SSH task to execute a SSH command on a remote computer as part of a Bamboo job. You can use the SSH task to do such things as:

- Calling database migration scripts
- Starting and stopping services
- Anything you can run on the command line on a remote machine

See [Configuring a deployment task](#) for an overview of Bamboo deployment tasks.

**Related pages:**
- Configuring a deployment task

### To configure an SSH task:

1. Navigate to the **Tasks** configuration tab for the job (this will be the default job if creating a new plan).
2. Click the name of an existing SSH task, or click **Add Task** and then **SSH Task** to create a new task.
3. Complete SSH task configuration settings.

   Starting from Bamboo version 6.3, you can choose shared credential as your authentication method. See [Shared credentials](#).

4. The shell command to execute on the remote host. You can only enter a single command here.
5. Click **Save**.

Host fingerprint

You can determine the fingerprint for a host by running:

```
ssh-keygen -l -F <HOSTNAME>
```

The fingerprint is the part of the response shown in the screenshot below:

Using Tomcat with Bamboo for continuous deployment

You can use Bamboo to deploy and manage your Java web application with Tomcat 6 or 7, without having to directly interact with Maven, Ant or write special scripts.

Bamboo provides tasks that use the HTTP-based scripting interface to the Tomcat Manager application that ships with Tomcat. You can use the Bamboo tasks to perform the following Tomcat operations:

- Deploy an application to a Tomcat instance
- Start an application in a Tomcat instance
- Stop an application in a Tomcat instance
- Reload an application to a Tomcat instance
- Undeploy an application from a Tomcat instance

Each of these tasks run as part of a Bamboo job.

### Setting up Tomcat

You will need to prepare the Tomcat server before Bamboo can manage and deploy applications to it.

1. Download the [Tomcat 7 distribution](https://tomcat.apache.org/download-75.cgi) and unzip it on your file system.
2. Add a new Tomcat user for Bamboo to use the Tomcat Application Manager by adding the following line in `conf/tomcat-users.xml` between the `<tomcat-users>` tags:

   ```xml
   <user username="bamboo" password="bamboo" roles="manager-script,manager-gui"/>
   ```

3. Start Tomcat by running `bin/startup.sh` on Linux or Mac, or `bin/startup.bat` on Windows.
4. Test this setup by browsing to [http://localhost:8080/manager](http://localhost:8080/manager) and using the username and password you configured in the step above. You should see the "Tomcat Web Application Manager" page, and a list of the running applications on your instance.

   For more information about the Tomcat Application Manager and its authentication and authorization configuration see the [Tomcat documentation](https://tomcat.apache.org/docs/70/tomcat-howto-tomcat-manager-guide.html).

### Deploying an application from Bamboo

You use Tomcat deployment tasks in the context of a job in a build plan in Bamboo. This plan should generate a deployable artifact, such as
To deploy the artifact, you add a Tomcat deploy task to the plan, as follows:

1. Navigate to the task configuration for the job (this will be the default job if you are creating a new plan).
2. Click Add Task and then Deploy Tomcat Application.
3. Configure the Tomcat task settings, as described below.
4. Click Save.
5. To deploy the application, simply run the plan.

You can check that the deployment has been successful by:

1. Navigating to the logs for the job. Towards the end you should see something like:

   ```
   > Deploying application with war file 'target/tomcat-test-0.1.war'
   to context '/myapp' to server [http://localhost:8080/manager/]
   > Application was successfully deployed.
   ```

   This indicates that Bamboo completed the task successfully.

   2. Now, browse to the expected address for your application. You should see the welcome page.

   **Configuring the Tomcat tasks**

   The Tomcat Deploy, Start, Stop, Undeploy and Reload tasks each make use of some or all of the following configuration settings:

   **Task Description**
   To help you to identify the task.

   **Disable this task**
   Check, or clear, to selectively run this task.

   **Tomcat Manager URL**
   The URL for the Tomcat Manager e.g. [http://localhost:8080/manager/](http://localhost:8080/manager/)

   **Target Tomcat server is version 6.x**
   Choose this if deploying to a Tomcat 6.x server.

   **Tomcat Manager Username and Password**
   These should match the credentials set in `conf/tomcat-users.xml` when you configured Tomcat, as described above.

   **Application Context**
   Specifies where the application should sit on the Tomcat server once deployed.

   **WAR File**
   The path to the WAR file, relative to the Bamboo working directory, for example "target/tomcat-test-0.1.war"

   **Deployment Tag**
   The value used to tag the deployment within the Tomcat Manager. You can use Bamboo variables to build the tag value.

   For example, using the value `${bamboo.buildResultKey}` will tag the deployment with the build number of the build that was used to deploy the application.

   **Using Tomcat with Bamboo for continuous deployment v5.14**

   You can use Bamboo to deploy and manage your Java web application with Tomcat 6 or 7, without having to directly interact with Maven, Ant or write special scripts.

   Bamboo provides tasks that use the HTTP-based scripting interface to the Tomcat Manager application that ships with Tomcat. You can use the Bamboo tasks to perform the following Tomcat operations:

   - Deploy an application to a Tomcat instance
   - Start an application in a Tomcat instance
   - Stop an application in a Tomcat instance
   - Reload an application to a Tomcat instance
   - Undeploy an application from a Tomcat instance

   Each of these tasks run as part of a Bamboo job.

   **On this page:**

   - Setting up Tomcat
   - Deploying an application from Bamboo
   - Configuring the Tomcat tasks
Setting up Tomcat

You will need to prepare the Tomcat server before Bamboo can manage and deploy applications to it.

1. Download the Tomcat 7 distribution and unzip it on your file system.
2. Add a new Tomcat user for Bamboo to use the Tomcat Application Manager by adding the following line in `conf/tomcat-users.xml` between the `<tomcat-users>` tags:

   ```xml
   <user username="bamboo" password="bamboo" roles="manager-script,manager-gui"/>
   ```

3. Start Tomcat by running `bin/startup.sh` on Linux or Mac, or `bin/startup.bat` on Windows.
4. Test this setup by browsing to `http://localhost:8080/manager` and using the username and password you configured in the step above. You should see the "Tomcat Web Application Manager" page, and a list of the running applications on your instance.

For more information about the Tomcat Application Manager and its authentication and authorization configuration see the Tomcat documentation.

Deploying an application from Bamboo

You use Tomcat deployment tasks in the context of a job in a build plan in Bamboo. This plan should generate a deployable artifact, such as a WAR file. To deploy the artifact, you add a Tomcat deploy task to the plan, as follows:

1. Navigate to the task configuration for the job (this will be the default job if you are creating a new plan).
2. Click Add Task and then Deploy Tomcat Application.
3. Configure the Tomcat task settings, as described below.
4. Click Save.
5. To deploy the application, simply run the plan.

You can check that the deployment has been successful by:

1. Navigating to the logs for the job. Towards the end you should see something like:

   ```
   > Deploying application with war file 'target/tomcat-test-0.1.war' to context '/myapp' to server [http://localhost:8080/manager/](http://localhost:8080/manager/) [http://localhost:8080/manager/]
   > Application was successfully deployed.
   ```

   This indicates that Bamboo completed the task successfully.
2. Now, browse to the expected address for your application. You should see the welcome page.

Configuring the Tomcat tasks

The Tomcat Deploy, Start, Stop, Undeploy and Reload tasks each make use of some or all of the following configuration settings:

<table>
<thead>
<tr>
<th>Task Description</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task Description</td>
<td>To help you to identify the task.</td>
</tr>
<tr>
<td>Disable this task</td>
<td>Check, or clear, to selectively run this task.</td>
</tr>
<tr>
<td>Tomcat Manager URL</td>
<td>The URL for the Tomcat Manager e.g. <code>http://localhost:8080/manager</code></td>
</tr>
<tr>
<td>Target Tomcat server is version 6.x</td>
<td>Choose this if deploying to a Tomcat 6.x server.</td>
</tr>
<tr>
<td>Tomcat Manager Username and Password</td>
<td>These should match the credentials set in <code>conf/tomcat-users.xml</code> when you configured Tomcat, as described above.</td>
</tr>
<tr>
<td>Application Context</td>
<td>Specifies where the application should sit on the Tomcat server once deployed.</td>
</tr>
</tbody>
</table>
### WAR File
The path to the WAR file, relative to the Bamboo working directory, for example “target/tomcat-test-0.1.war”

### Deployment Tag
The value used to tag the deployment within the Tomcat Manager. You can use Bamboo variables to build the tag value. For example, using the value `${bamboo.buildResultKey}` will tag the deployment with the build number of the build that was used to deploy the application.

### Using Tomcat with Bamboo for continuous deployment v6.1
You can use Bamboo to deploy and manage your Java web application with Tomcat 6 or 7, without having to directly interact with Maven, Ant or write special scripts.

Bamboo provides tasks that use the HTTP-based scripting interface to the Tomcat Manager application that ships with Tomcat. You can use the Bamboo tasks to perform the following Tomcat operations:

- Deploy an application to a Tomcat instance
- Start an application in a Tomcat instance
- Stop an application in a Tomcat instance
- Reload an application to a Tomcat instance
- Undeploy an application from a Tomcat instance

Each of these tasks run as part of a Bamboo job.

#### Setting up Tomcat
You will need to prepare the Tomcat server before Bamboo can manage and deploy applications to it.

1. Download the [Tomcat 7 distribution](https://tomcat.apache.org/) and unzip it on your file system.
2. Add a new Tomcat user for Bamboo to use the Tomcat Application Manager by adding the following line in `conf/tomcat-users.xml` between the `<tomcat-users>` tags:

   ```xml
   <user username="bamboo" password="bamboo" roles="manager-script,manager-gui"/>
   ```

3. Start Tomcat by running `bin/startup.sh` on Linux or Mac, or `bin/startup.bat` on Windows.
4. Test this setup by browsing to [http://localhost:8080/manager](http://localhost:8080/manager) and using the username and password you configured in the step above. You should see the “Tomcat Web Application Manager” page, and a list of the running applications on your instance.

   For more information about the Tomcat Application Manager and its authentication and authorization configuration see the [Tomcat documentation](https://tomcat.apache.org/).

#### Deploying an application from Bamboo
You use Tomcat deployment tasks in the context of a job in a build plan in Bamboo. This plan should generate a deployable artifact, such as a WAR file. To deploy the artifact, you add a Tomcat deploy task to the plan, as follows:

1. Navigate to the task configuration for the job (this will be the default job if you are creating a new plan).
2. Click **Add Task** and then **Deploy Tomcat Application**.
3. Configure the Tomcat task settings, as described below.
4. Click **Save**.
5. To deploy the application, simply run the plan.

You can check that the deployment has been successful by:

1. Navigating to the logs for the job. Towards the end you should see something like:
This indicates that Bamboo completed the task successfully.
2. Now, browse to the expected address for your application. You should see the welcome page.

Configuring the Tomcat tasks

The Tomcat Deploy, Start, Stop, Undeploy and Reload tasks each make use of some or all of the following configuration settings:

**Task Description**
To help you to identify the task.

**Disable this task**
Check, or clear, to selectively run this task.

**Tomcat Manager URL**
The URL for the Tomcat Manager e.g. http://localhost:8080/manager/

**Target Tomcat server is version 6.x**
Choose this if deploying to a Tomcat 6.x server.

**Tomcat Manager Username and Password**
These should match the credentials set in conf/tomcat-users.xml when you configured Tomcat, as described above.

**Application Context**
Specifies where the application should sit on the Tomcat server once deployed.

**WAR File**
The path to the WAR file, relative to the Bamboo working directory, for example “target/tomcat-test-0.1.war”

**Deployment Tag**
The value used to tag the deployment within the Tomcat Manager. You can use Bamboo variables to build the tag value.
For example, using the value ${bamboo.buildResultKey} will tag the deployment with the build number of the build that was used to deploy the application.

Using the Heroku task in Bamboo

You can use Bamboo to deploy your Java web application to the Heroku cloud platform.

The plan that does this:

- Should have access to the previously created WAR artifact. For example, in Maven-based projects, this would typically be created using the package goal. See Sharing artifacts.
- Should use the Heroku: Deploy WAR Artifact task. To configure this task, specify the API Key, App Name, and WAR File to use. Your API key can be found on the Heroku account page. If the app name specified does not exist, it will be created for you. The WAR file value should be the relative path to the WAR artifact.

To find out more, go to the Heroku documentation:

- Getting started with the Heroku plugin for Atlassian Bamboo
- Getting started with Java on Heroku

Note that the Heroku task is bundled with Bamboo 4.3, and later, but is also available from the Atlassian Marketplace.

*Using the Heroku task in Bamboo v5.14*

You can use Bamboo to deploy your Java web application to the Heroku cloud platform.

The plan that does this:

- Should have access to the previously created WAR artifact. For example, in Maven-based projects, this would typically be created using the package goal. See Sharing artifacts.
• Should use the **Heroku: Deploy WAR Artifact** task. To configure this task, specify the **API Key**, **App Name**, and **WAR File** to use. Your API key can be found on the Heroku account page. If the app name specified does not exist, it will be created for you. The WAR file value should be the relative path to the WAR artifact.

To find out more, go to the Heroku documentation:

- Getting started with the Heroku plugin for Atlassian Bamboo
- Getting started with Java on Heroku

Note that the Heroku task is bundled with Bamboo 4.3, and later, but is also available from the Atlassian Marketplace.

### Using the Heroku task in Bamboo v6.6

Using the AWS CodeDeploy task

With the AWS CodeDeploy task for Bamboo you can deploy applications to EC2 instances automatically, reliably, and rapidly. Additionally, AWS CodeDeploy keeps track of the whole deployment process.

On this page:

- Overview
- Before you begin
- Adding an AWS CodeDeploy task to a Bamboo plan
- AWS CodeDeploy configuration for Bamboo
- Preparing files for deployment
  - Examples of revisions

#### Overview

The AWS CodeDeploy task compresses the specified directory with an AppSpec file into a .zip file, uploads the file to Amazon S3, and starts the deployment according to the configuration provided in the CodeDeploy application.

#### Further reading

- What is AWS CodeDeploy?
- AWS CodeDeploy deployments

#### Before you begin

There are several requirements that must be met before you can start using the AWS CodeDeploy task. In short, you must configure the following in your AWS Management Console:

- an EC2 instance with a tagged deployment group
- a CodeDeploy application
- an IAM user
- an S3 bucket

For more guidelines about your AWS configuration, see AWS CodeDeploy configuration for Bamboo.

The content that you want to be zipped and deployed requires a specific structure. For more information, see Preparing files for...
Adding an AWS CodeDeploy task to a Bamboo plan

To use the CodeDeploy task:

1. Go to the plan configuration.
2. Click **Add task**.
3. Select **AWS CodeDeploy**.
4. Provide the following details:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task description</td>
<td>A short description of the task.</td>
</tr>
<tr>
<td>Disable this task</td>
<td>Select the check box to skip this task in the build.</td>
</tr>
<tr>
<td>AWS credentials</td>
<td>You can select existing AWS credentials from the list or add new AWS credentials. The newly created AWS credentials are added to the shared credentials list in Bamboo. To make existing AWS credentials available for selection within the AWS CodeDeploy task in Bamboo, add them to <strong>Shared credentials</strong>.</td>
</tr>
<tr>
<td>Region</td>
<td>A region in which the application is deployed.</td>
</tr>
<tr>
<td>Deployable content directory</td>
<td>Location of the directory that contains the deployable content and an AppSpec file. By default, it is the root build directory. The content of the directory is compressed into a .zip file and sent to Amazon S3 bucket for deployment. For more information, see <a href="#">Preparing files for deployment</a>.</td>
</tr>
<tr>
<td>Amazon S3 bucket</td>
<td>The name of an S3 bucket from which the deployable content (your app and the AppSpec file) is deployed. Start typing to open a selection list of the existing S3 buckets that are available for the AWS credentials provided in the task configuration. For more information, see <a href="#">Amazon S3 bucket</a>.</td>
</tr>
<tr>

**AWS CodeDeploy configuration for Bamboo**

The infrastructure setup is described in detail by AWS. For more information, see [Getting Started with AWS CodeDeploy](#).

Atlassian provides guidelines for the following:

- **IAM user**
- **AWS CodeDeploy application**
- **Amazon S3 bucket**

**IAM user**

We recommend creating a dedicated CodeDeploy IAM user or group.

The following policy gives full permissions to Amazon S3 buckets, CodeDeploy application and deployment group:

### Further reading

- **AWS CodeDeploy User Access Permissions Reference**
- **Create IAM Instance Profile and Service roles**

To make existing AWS credentials available for selection within the AWS
For more examples of policies, see Bucket Policy Examples.

**AWS CodeDeploy application**

Each CodeDeploy application holds information about the deployment configuration.

For more information, see Create an Application with AWS CodeDeploy.

**Amazon S3 bucket**

An Amazon S3 bucket must exist. We recommend creating a dedicated CodeDeploy S3 bucket that is located in the same region as the instances to which you want to deploy the application.

For more information about how to grant access to S3 buckets, see IAM user.

## Preparing files for deployment

The deployable content that is compressed and sent to an Amazon S3 bucket is called a revision and it consists of the application and an AppSpec (Application Specification) file.

### Examples of revisions

- simple
- advanced

### Using the AWS CodeDeploy task v5.14

With the AWS CodeDeploy task for Bamboo you can deploy applications to EC2 instances automatically, reliably, and rapidly. Additionally, AWS CodeDeploy keeps track of the whole deployment process.

On this page:

- Overview
- Before you begin
- Adding an AWS CodeDeploy task to a Bamboo plan
- AWS CodeDeploy configuration for Bamboo
- Preparing files for deployment
  - Examples of revisions
The AWS CodeDeploy task compresses the specified directory with an AppSpec file into a .zip file, uploads the file to Amazon S3, and starts the deployment according to the configuration provided in the CodeDeploy application.

**Before you begin**

There are several requirements that must be met before you can start using the AWS CodeDeploy task. In short, you must configure the following in your AWS Management Console:

- an EC2 instance with a tagged deployment group
- a CodeDeploy application
- an IAM user
- an S3 bucket

For more guidelines about your AWS configuration, see [AWS CodeDeploy configuration for Bamboo](#).

The content that you want to be zipped and deployed requires a specific structure. For more information, see [Preparing files for deployment](#).

### Adding an AWS CodeDeploy task to a Bamboo plan

To use the CodeDeploy task:

1. Go to the plan configuration.
2. Click **Add task**.
3. Select **AWS CodeDeploy**.
4. Provide the following details:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task description</td>
<td>A short description of the task.</td>
</tr>
<tr>
<td>Disable this task</td>
<td>Select the check box to skip this task in the build.</td>
</tr>
<tr>
<td>AWS credentials</td>
<td>You can select existing AWS credentials from the list or add new AWS credentials. The newly created AWS credentials are added to the shared credentials list in Bamboo. To make existing AWS credentials available for selection within the AWS CodeDeploy task in Bamboo, add them to <strong>Shared credentials</strong>.</td>
</tr>
<tr>
<td>Region</td>
<td>A region in which the application is deployed.</td>
</tr>
<tr>
<td>Deployable content directory</td>
<td>Location of the directory that contains the deployable content and an AppSpec file. By default, it is the root build directory. The content of the directory is compressed into a .zip file and sent to Amazon S3 bucket for deployment. For more information, see <a href="#">Preparing files for deployment</a>.</td>
</tr>
<tr>
<td>Amazon S3 bucket</td>
<td>The name of an S3 bucket from which the deployable content (your app and the AppSpec file) is deployed. Start typing to open a selection list of the existing S3 buckets that are available for the AWS credentials provided in the task configuration. For more information, see <a href="#">Amazon S3 bucket</a>.</td>
</tr>
</tbody>
</table>

Further reading

**AWS CodeDeploy configuration for Bamboo**

The infrastructure setup is described in detail by AWS. For more information, see Getting Started with AWS CodeDeploy.

Atlassian provides guidelines for the following:

- IAM user
- AWS CodeDeploy application
- Amazon S3 bucket

I AM user

We recommend creating a dedicated CodeDeploy IAM user or group. The following policy gives full permissions to Amazon S3 buckets, CodeDeploy application and deployment group:

```json
{
   "Version": "2012-10-17",
   "Statement": [
       {
           "Effect": "Allow",
           "Action": [
               "codedeploy:*",
               "s3:*
           ],
           "Resource": "*"
       }
   ]
}
```

For more examples of policies, see Bucket Policy Examples.

**AWS CodeDeploy application**

Each CodeDeploy application holds information about the deployment configuration.

For more information, see Create an Application with AWS CodeDeploy.

**Amazon S3 bucket**

An Amazon S3 bucket must exist. We recommend creating a dedicated CodeDeploy S3 bucket that is located in the same region as the instances to which you want to deploy the application.

**Further reading**

- AWS CodeDeploy
- User Access Permissions Reference

To make existing AWS credentials available for selection within the AWS CodeDeploy task in Bamboo, add them to Shared credentials.
Preparing files for deployment

The deployable content that is compressed and sent to an Amazon S3 bucket is called a revision and it consists of the application and an AppSpec (Application Specification) file.

Examples of revisions

- simple
- advanced

Pattern matching reference

Bamboo supports a powerful type of regular expression for matching files and directories (as with pattern matching in Apache Ant).

These expressions use the following wildcards:

- ?
  - Matches one character (any character except path separators)
- *
  - Matches zero or more characters (not including path separators)
- **
  - Matches zero or more path segments.

Remember that Ant globs match paths, not just simple filenames.

- If the pattern does not start with a path separator i.e. / or \, then the pattern is considered to start with /**/.
- If the pattern ends with / then ** is automatically appended.
- A pattern can contain any number of wildcards.

Also see the Ant documentation.

Examples

*.txt
Matches /foo.txt and /bar/foo.txt but not /foo.txty or /bar/foo.txty/

/*.txt
Matches /foo.txt but not /bar/foo.txt

dir1/file.txt

/**/dir1/file.txt

/**/dir1/file.txt

/dir3/**/dir1/file.txt

/dir1/**
Matches all files under /dir1/

.Pattern matching reference v5.14
Bamboo supports a powerful type of regular expression for matching files and directories (as with pattern matching in Apache Ant).

These expressions use the following wildcards:

<table>
<thead>
<tr>
<th>Wildcard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Matches one character (any character except path separators)</td>
</tr>
<tr>
<td>*</td>
<td>Matches zero or more characters (not including path separators)</td>
</tr>
<tr>
<td>**</td>
<td>Matches zero or more path segments.</td>
</tr>
</tbody>
</table>

Remember that Ant globs match *paths*, not just simple filenames.

- If the pattern does not start with a path separator i.e. / or \, then the pattern is considered to start with /**/.
- If the pattern ends with / then ** is automatically appended.
- A pattern can contain any number of wildcards.

Also see the [Ant documentation](#).

### Examples

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Matches</th>
</tr>
</thead>
<tbody>
<tr>
<td>*.txt</td>
<td>/foo.txt and /bar/foo.txt but not /foo.txty or /bar/foo.txt/</td>
</tr>
<tr>
<td>*/.txt</td>
<td>/foo.txt but not /bar/foo.txt</td>
</tr>
<tr>
<td>**/dir1/file.txt</td>
<td>Same as above.</td>
</tr>
<tr>
<td>/*/*dir1/file.txt</td>
<td>Same as above.</td>
</tr>
<tr>
<td>/dir1/**</td>
<td>Matches all files under /dir1/</td>
</tr>
</tbody>
</table>

.Pattern matching reference v6.1

Bamboo supports a powerful type of regular expression for matching files and directories (as with pattern matching in Apache Ant).

These expressions use the following wildcards:

<table>
<thead>
<tr>
<th>Wildcard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Matches one character (any character except path separators)</td>
</tr>
<tr>
<td>*</td>
<td>Matches zero or more characters (not including path separators)</td>
</tr>
<tr>
<td>**</td>
<td>Matches zero or more path segments.</td>
</tr>
</tbody>
</table>

Remember that Ant globs match *paths*, not just simple filenames.

- If the pattern does not start with a path separator i.e. / or \, then the pattern is considered to start with /**/.
- If the pattern ends with / then ** is automatically appended.
- A pattern can contain any number of wildcards.

Also see the [Ant documentation](#).

### Examples

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Matches</th>
</tr>
</thead>
<tbody>
<tr>
<td>*.txt</td>
<td>/foo.txt and /bar/foo.txt but not /foo.txty or /bar/foo.txt/</td>
</tr>
<tr>
<td>*/.txt</td>
<td>/foo.txt but not /bar/foo.txt</td>
</tr>
<tr>
<td>**/dir1/file.txt</td>
<td>Same as above.</td>
</tr>
<tr>
<td>/*/*dir1/file.txt</td>
<td>Same as above.</td>
</tr>
<tr>
<td>/dir1/**</td>
<td>Matches all files under /dir1/</td>
</tr>
</tbody>
</table>
**Configuring the Docker task in Bamboo**

The Docker task in Atlassian Bamboo allows you to use Docker images and containers in your Bamboo builds and deployments.

---

**If you're using a Windows Bamboo server**, you can't run Docker commands directly from the Windows command line. To use the Docker task with a Windows Bamboo server, run Docker Machine.

---

The Docker task supports the following Docker actions:

- Build a Docker image
- Run a Docker container
- Push a Docker repository to a Docker registry

Remember to define a Docker capability on an agent before you configure a Docker task.

For examples of how to use Docker in Bamboo, see the Bamboo, Docker, and building web apps blog post.

Note that Bamboo requires Docker 1.7.1 or later. See also Getting started with Docker and Bamboo for information about how to manage and run your Bamboo remote agents using Docker.

---

**Build a Docker image**

Builds a Docker image based on the specified Dockerfile. The Dockerfile may be provided as an existing file in the task's working directory or defined in the task configuration.

The image is stored in Docker's local image installation directory and can be used by subsequent Docker tasks in the job. You can optionally save the image to a file in the working directory which can then be packaged as a build artifact.

To build a Docker image in Bamboo:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Build a Docker image command and complete the settings. Click below to see more information about the settings:
   - Build a Docker image...
**Repository**

The repository name (and optionally a tag) to be applied to the resulting image, following this pattern:

```
registry.address:port/namespace/repository:tag
```

Only repository is mandatory.

**Dockerfile**

Use either an existing Dockerfile (located in the working directory for the task), or specify the contents of the Dockerfile.

**Do not use cache when building the image**

By default, Docker will reuse a cached build during the next build. See the [Docker documentation](https://docs.docker.com). Select **Do not use cache...** to ensure that the new image will include changes since the last build. Note that this may incur a performance penalty.

**Save the image as a file**

Specify the directory location and file name. Optionally configure a **job artifact** to pass it to next stages and deployments.

If required, specify advanced options:

**Environment variables**

(Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g `JAVA_OPTS=-Xms200m -Xmx700m`).

**Working sub directory**

(Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

**Run a Docker container**

Starts a Docker container based on the specified image.

By default, the task's working directory is mounted and used as the Docker container's working directory, but you can specify your own.
settings.

By default, the container is removed on completion of the task, but you can choose Detach container to have the container continue to run after a deployment project completes. Containers can be linked to detached containers started by preceding tasks in a job by selecting the 'Link to detached containers' option.

Note that a non-detached container that fails to start will not be removed when the Bamboo task completes. See this KB article for more details.

To run a Docker container in Bamboo:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Run a Docker container command and complete the settings. Click below to see more information about the settings:

   ![Docker container settings](image)

   - **Docker image**
     - The image you want to use to instantiate the Docker container
   - **Detach container**
     - Allows you to run the container in the background, after a deployment project completes
     - Specify a Container name that isn't used by other containers in this job.
     - Click Add port mapping to specify mappings that bind ports inside the container to ports on the host.
   - **Wait for service to start**
     - Allows you to specify how long Bamboo should wait for the service to become available.
     - You need to specify a pattern for the URL that Bamboo should check, and a timeout period.
   - **Link to detached containers**
     - Allows you to link containers to detached containers started by preceding tasks in a job.
   - **Container environment variables**
     - Allows you to specify parameters to pass to the container, for example `JAVA_OPTS=-Xmx256m -Xms128m`. Separate multiple parameters with spaces. Parameters with spaces must be quoted.
   - **Container command**
     - The command to run in the Docker container.
   - **Container working directory**
The working directory for the container.

**Additional arguments**

Additional Docker run options.

Argument strings that have values which contain spaces require the entire argument string be contained within quotes, that is, the parameter marker, the parameter, the equals sign, and the value containing spaces. For example:

```
"--health-cmd=mysqladmin ping || exit 1"
```

**Volumes**

You can mount additional host directories as data volumes inside the container.

If required, specify advanced options:

**Environment variables**

(Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables).

Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g JAVA_OPTS="-Xms200m -Xmx700m").

**Working sub directory**

(Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

*Save your changes!*

---

**Push a Docker image to a Docker registry**

Pushes a Docker image to a Docker registry. This may be the central Docker Hub registry or a custom registry.

To push a Docker image from Bamboo to a registry:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Push a Docker image to a Docker registry command and complete the settings. Click below to see more information about the settings:

   - Push a Docker image to a Docker registry...
### Registry

Choose to push to either Docker Hub or a custom registry.

### Repository

For Docker Hub you must specify the repository name and optionally a tag, for example: namespace/repository:tag

For a custom registry you must specify the registry address, repository name and optionally a tag, for example: registry.address:port/namespace/repository:tag

### Username, Password, Email

Credentials for the registry account. Leave it empty to use agents' dockercfg file.

If required, specify advanced options:

#### Environment variables

*(Optional)* Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g JAVA_OPTS="-Xms200m -Xmx700m").

#### Working sub directory

*(Optional)* An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Save your changes!

---

**Advanced authentication**

The push task allows you to define username, password and email for authentication purposes.

If the other tasks require authentication, or if you want to share credentials between all builds for certain agents, it's possible to create the docker configuration file on the agent itself, named ~/.dockercfg:
When using the push task, leave authentication fields empty in order to use dockerconfig instead.

Docker command updates ~/.dockercfg file; if you have any configuration management tool in place updating this file (like puppet, chef or ansible), make sure it's not executing while you are running a docker build.

**Troubleshooting**

No space left on device

Docker stores it's images in a local image installation directory. Over time this directory may grow to consume all of the available disk space. When this occurs you should remove unused images by running the `docker rmi` command.

The following Docker issues affecting disk space may provide further information:

- Device-mapper does not release free space from removed images
- Graph deletes are non-atomic, db refs deleted without deleting on-disk entities

Permission denied on files created within a Docker container

Docker runs processes inside containers as the root user. This means files created on mounted volumes are owned by the root user and not by the user running the Docker command (the bamboo agent user). This may cause an issue if a subsequent task requires access to those files on the host.

Docker plans to allow mapping between container and host users in the future. Until then, you can work around this issue by changing the owner of the files in the mounted volume to the host user:

- Supply the host user's id and group id to the container by setting the following environment variables in the Docker run task configuration:
  * HOST_UID=$UID
  * HOST_GID=$GID
- Run a script inside the container to change the owner of the files in the mounted volume:

  ```bash
  chown -R $HOST_UID:$HOST_GID /<path_to_mounted_volume>
  ```

Permission denied when running Docker

When attempting to run a Docker container you may see a 'permission denied' issue:

```
2015/02/10 06:35:31 Post
http://var/run/docker.sock/build?rm=1&t=docker-toy-demo: dial unix
/var/run/docker.sock: permission denied
```

The solution is to add the Bamboo user agent to the Docker group on the agent.

Getting execution errors for valid docker files or unable to start docker container

Example build output:

```
Driver devicemapper failed to get image rootfs
511136ea3c5a64f264b78b5433614aec563103b4d47027a7d4d2698e22c158: Error mounting

If the agent consistently fails executing docker run commands, either when building an image or running an instance there is a risk that you've run into. To help diagnose this you can SSH to the agent and look at the kernel messages by running:

dmesg

There are several possible messages that indicate this problem. Some of those are listed here:

```
[83471099.881879] JBD2: no valid journal superblock found
[83471099.881883] EXT4-fs (dm-2): error loading journal
[88401612.723018] EXT4-fs (dm-1): warning: mounting fs with errors, running e2fsck is recommended
[88401612.724764] EXT4-fs (dm-1): mounted filesystem with ordered data mode. Opts: discard
```

There is a big risk that the device mapper is corrupt. This means that you need to stop Docker and remove the files used by devicemapper, then restart Docker. If running on an elastic agent, terminating the agent and starting a new one is also a viable option.

To stop Docker and remove the files, run the following:

```
sudo -i
#stop the docker daemon
service docker stop
#remove the broken devicemapper files
rm -rf /var/lib/docker
service docker start
```

The location of the devicemapper files may differ from the example above. Run the following to find the exact path:

```
docker info
```

Configuring the Docker task in Bamboo v5.14

The Docker task in Atlassian Bamboo allows you to use Docker images and containers in your Bamboo builds and deployments.

If you're using a Windows Bamboo server, you can't run Docker commands directly from the Windows command line. To use the Docker task with a Windows Bamboo server, run Docker Machine.

The Docker task supports the following Docker actions:

- Build a Docker image
- Run a Docker container
• Push a Docker repository to a Docker registry

Remember to define a Docker capability on an agent before you configure a Docker task.

For examples of how to use Docker in Bamboo, see the Bamboo, Docker, and building web apps blog post.

Note that Bamboo requires Docker 1.7.1 or later. See also Getting started with Docker and Bamboo for information about how to manage and run your Bamboo remote agents using Docker.

Build a Docker image

Builds a Docker image based on the specified Dockerfile. The Dockerfile may be provided as an existing file in the task's working directory or defined in the task configuration.

The image is stored in Docker’s local image installation directory and can be used by subsequent Docker tasks in the job. You can optionally save the image to a file in the working directory which can then be packaged as a build artifact.

To build a Docker image in Bamboo:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Build a Docker image command and complete the settings. Click below to see more information about the settings:

   • Build a Docker image...
Repository

The repository name (and optionally a tag) to be applied to the resulting image, following this pattern:

registry.address:port/namespace/repository:tag

Only repository is mandatory.

Dockerfile

Use either an existing Dockerfile (located in the working directory for the task), or specify the contents of the Dockerfile.

Do not use cache when building the image

By default, Docker will reuse a cached build during the next build. See the Docker documentation.

Select Do not use cache... to ensure that the new image will include changes since the last build. Note that this may incur a performance penalty.

Save the image as a file

Specify the directory location and file name. Optionally configure a job artifact to pass it to next stages and deployments.

If required, specify advanced options:

Environment variables

(Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g JAVA_OPTS="-Xms200m -Xmx700m").

Working sub directory

(Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Save your changes!
settings.

By default, the container is removed on completion of the task, but you can choose Detach container to have the container continue to run after a deployment project completes. Containers can be linked to detached containers started by preceding tasks in a job by selecting the 'Link to detached containers' option.

Note that a non-detached container that fails to start will not be removed when the Bamboo task completes. See this KB article for more details.

To run a Docker container in Bamboo:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Run a Docker container command and complete the settings. Click below to see more information about the settings:

   Run a Docker container...
**Docker image**

The image you want to use to instantiate the Docker container

**Detach container**

Allows you to run the container in the background, after a deployment project completes

Specify a **Container name** that isn’t used by other containers in this job.

Click **Add port mapping** to specify mappings that bind ports inside the container to ports on the host.

**Wait for service to start**

Allows you to specify how long Bamboo should wait for the service to become available.

You need to specify a pattern for the URL that Bamboo should check, and a timeout period.

**Link to detached containers**

Allows you to link containers to detached containers started by preceding tasks in a job.

**Container environment variables**

Allows you to specify parameters to pass to the container, for example `JAVA_OPTS="-Xmx256m -Xms128m"`.

Separate multiple parameters with spaces. Parameters with spaces must be quoted.

**Container command**

The command to run in the Docker container.

**Container working directory**

The working directory for the container.

**Additional arguments**

Additional Docker run options.

**Volumes**

You can mount additional host directories as data volumes inside the container.

---

If required, specify advanced options:
Environment variables

(Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g. JAVA_OPTS="-Xms200m -Xmx700m").

Working sub directory

(Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Save your changes!

Push a Docker image to a Docker registry

Pushes a Docker image to a Docker registry. This may be the central Docker Hub registry or a custom registry.

To push a Docker repository from Bamboo to a registry:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Push a Docker image to a Docker registry command and complete the settings. Click below to see more information about the settings:

   Push a Docker image to a Docker registry...
### Registry

Choose to push to either Docker Hub or a custom registry.

### Repository

For Docker Hub you must specify the repository name and optionally a tag, for example: namespace/repository:tag. For a custom registry you must specify the registry address, repository name and optionally a tag, for example: registry.address:port/namespace/repository:tag.

#### Username, Password, Email

Credentials for the registry account. Leave it empty to use agents’ dockercfg file.

If required, specify advanced options:

### Environment variables

*(Optional)* Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g JAVA_OPTS="-Xms200m -Xmx700m").

### Working sub directory

*(Optional)* An alternative subdirectory, relative to the job’s root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job’s configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Save your changes!

---

### Advanced authentication

The push task allows you to define username, password and email for authentication purposes.

If the other tasks require authentication, or if you want to share credentials between all builds for certain agents, it’s possible to create the docker configuration file on the agent itself, named ~/.dockercfg.
When using the push task, leave authentication fields empty in order to use dockercfg instead.

Docker command updates ~/.dockercfg file; if you have any configuration management tool in place updating this file (like puppet, chef or ansible), make sure it's not executing while you are running a docker build.

Troubleshooting

No space left on device

Docker stores it's images in a local image installation directory. Over time this directory may grow to consume all of the available disk space. When this occurs you should remove unused images by running the docker rmi command.

The following Docker issues affecting disk space may provide further information:

- Device-mapper does not release free space from removed images
- Graph deletes are non-atomic, db refs deleted without deleting on-disk entities

Permission denied on files created within a Docker container

Docker runs processes inside containers as the root user. This means files created on mounted volumes are owned by the root user and not by the user running the Docker command (the bamboo agent user). This may cause an issue if a subsequent task requires access to those files on the host.

Docker plans to allow mapping between container and host users in the future. Until then, you can work around this issue by changing the owner of the files in the mounted volume to the host user:

Supply the host user's id and group id to the container by setting the following environment variables in the Docker run task configuration:

- HOST_UID=$UID
- HOST_GID=$GID

Run a script inside the container to change the owner of the files in the mounted volume:

```
chown -R $HOST_UID:$HOST_GID /<path_to_mounted_volume>
```

Permission denied when running Docker

When attempting to run a Docker container you may see a 'permission denied' issue:

```
2015/02/10 06:35:31 Post
http:///var/run/docker.sock/build?rm=1&t=docker-toy-demo: dial unix /var/run/docker.sock: permission denied
```

The solution is to add the Bamboo user agent to the Docker group on the agent.

Getting execution errors for valid docker files or unable to start docker container

Example build output:

```
Driver devicemapper failed to get image rootfs
511136ea3c5a64f264b78b5433614aec563103b4d4702f3ba7d4d2698e22c158: Error mounting

.**Configuring the Docker task in Bamboo v5.15**

The Docker task in Atlassian Bamboo allows you to use Docker images and containers in your Bamboo builds and deployments.

**If you're using a Windows Bamboo server**, you can't run Docker commands directly from the Windows command line. To use the Docker task with a Windows Bamboo server, run Docker Machine.

The Docker task supports the following Docker actions:

- Build a Docker image
- Run a Docker container
• Push a Docker repository to a Docker registry

Remember to define a Docker capability on an agent before you configure a Docker task.

For examples of how to use Docker in Bamboo, see the Bamboo, Docker, and building web apps blog post.

Note that Bamboo requires Docker 1.7.1 or later. See also Getting started with Docker and Bamboo for information about how to manage and run your Bamboo remote agents using Docker.

Build a Docker image

Builds a Docker image based on the specified Dockerfile. The Dockerfile may be provided as an existing file in the task’s working directory or defined in the task configuration.

The image is stored in Docker’s local image installation directory and can be used by subsequent Docker tasks in the job. You can optionally save the image to a file in the working directory which can then be packaged as a build artifact.

To build a Docker image in Bamboo:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Build a Docker image command and complete the settings. Click below to see more information about the settings:
   ◀️ Build a Docker image...
**Repository**

The repository name (and optionally a tag) to be applied to the resulting image, following this pattern:

```
registry.address:port/namespace/repository:tag
```

Only `repository` is mandatory.

**Dockerfile**

Use either an existing Dockerfile (located in the working directory for the task), or specify the contents of the Dockerfile.

**Do not use cache when building the image**

By default, Docker will reuse a cached build during the next build. See the Docker documentation.

Select **Do not use cache...** to ensure that the new image will include changes since the last build. Note that this may incur a performance penalty.

**Save the image as a file**

Specify the directory location and file name. Optionally configure a **job artifact** to pass it to next stages and deployments.

If required, specify advanced options:

**Environment variables**

(Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g `JAVA_OPTS=-Xms200m -Xmx700m`).

**Working sub directory**

(Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Save your changes!

**Run a Docker container**

Starts a Docker container based on the specified image.

By default, the task's working directory is mounted and used as the Docker container's working directory, but you can specify your own
settings.

By default, the container is removed on completion of the task, but you can choose Detach container to have the container continue to run after a deployment project completes. Containers can be linked to detached containers started by preceding tasks in a job by selecting the 'Link to detached containers' option.

Note that a non-detached container that fails to start will not be removed when the Bamboo task completes. See this KB article for more details.

To run a Docker container in Bamboo:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Run a Docker container command and complete the settings. Click below to see more information about the settings:

**Advanced authentication**

The push task allows you to define username, password and email for authentication purposes.

If the other tasks require authentication, or if you want to share credentials between all builds for certain agents, it’s possible to create the `docker configuration file on the agent itself, named ~/.dockercfg`.

---

*Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.*
When using the push task, leave authentication fields empty in order to use dockercfg instead.

Docker command updates ~/.dockercfg file; if you have any configuration management tool in place updating this file (like puppet, chef or ansible), make sure it's not executing while you are running a docker build.

Troubleshooting

No space left on device

Docker stores its images in a local image installation directory. Over time this directory may grow to consume all of the available disk space. When this occurs you should remove unused images by running the `docker rmi` command.

The following Docker issues affecting disk space may provide further information:

- Device-mapper does not release free space from removed images
- Graph deletes are non-atomic, db refs deleted without deleting on-disk entities

Permission denied on files created within a Docker container

Docker runs processes inside containers as the root user. This means files created on mounted volumes are owned by the root user and not by the user running the Docker command (the bamboo agent user). This may cause an issue if a subsequent task requires access to those files on the host.

Docker plans to allow mapping between container and host users in the future. Until then, you can work around this issue by changing the owner of the files in the mounted volume to the host user:

- Supply the host user's id and group id to the container by setting the following environment variables in the Docker run task configuration:
  - `HOST_UID=$UID`
  - `HOST_GID=$GID`
- Run a script inside the container to change the owner of the files in the mounted volume:

  ```bash
  chown -R $HOST_UID:$HOST_GID /<path_to_mounted_volume>
  ```

Permission denied when running Docker

When attempting to run a Docker container you may see a ‘permission denied’ issue:

```
2015/02/10 06:35:31 Post
http:///var/run/docker.sock/build?rm=1&t=docker-toy-demo: dial unix /var/run/docker.sock: permission denied
```

The solution is to add the Bamboo user agent to the Docker group on the agent.

Getting execution errors for valid docker files or unable to start docker container

Example build output:

```
Driver devicemapper failed to get image rootfs
511136ea3c5a64f264b78b5433614aeca563103b4d4702f3ba7d4d2698e22c158: Error mounting

If the agent consistently fails executing docker run commands, either when building an image or running an instance there is a risk that you've run into https://github.com/docker/docker/issues/4036 To help diagnose this you can SSH to the agent and look at the kernel messages by running:

dmesg

There are several possible messages that indicate this problem. Some of those are listed here:

[83471099.881879] JBD2: no valid journal superblock found
[83471099.881883] EXT4-fs (dm-2): error loading journal
[88401612.723018] EXT4-fs (dm-1): warning: mounting fs with errors, running e2fsck is recommended
[88401612.724764] EXT4-fs (dm-1): mounted filesystem with ordered data mode. Opts: discard

There is a big risk that the device mapper is corrupt. This means that you need to stop Docker and remove the files used by devicemapper, then restart Docker. If running on an elastic agent, terminating the agent and starting a new one is also a viable option.

To stop Docker and remove the files, run the following:

```
sudo -i
#stop the docker daemon
service docker stop
#remove the broken devicemapper files
rm -rf /var/lib/docker
service docker start
```

The location of the devicemapper files may differ from the example above. Run the following to find the exact path:

docker info

. Configuring the Docker task in Bamboo v6.2

The Docker task in Atlassian Bamboo allows you to use Docker images and containers in your Bamboo builds and deployments.

**If you're using a Windows Bamboo server**, you can't run Docker commands directly from the Windows command line.

To use the Docker task with a Windows Bamboo server, run Docker Machine.

The Docker task supports the following Docker actions:

- Build a Docker image
- Run a Docker container
• **Push a Docker repository to a Docker registry**

Remember to define a Docker capability on an agent before you configure a Docker task.

For examples of how to use Docker in Bamboo, see the Bamboo, Docker, and building web apps blog post.

Note that Bamboo requires Docker 1.7.1 or later. See also Getting started with Docker and Bamboo for information about how to manage and run your Bamboo remote agents using Docker.

**Build a Docker image**

Builds a Docker image based on the specified Dockerfile. The Dockerfile may be provided as an existing file in the task’s working directory or defined in the task configuration.

The image is stored in Docker’s local image installation directory and can be used by subsequent Docker tasks in the job. You can optionally save the image to a file in the working directory which can then be packaged as a build artifact.

To build a Docker image in Bamboo:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Build a Docker image command and complete the settings. Click below to see more information about the settings:
   
   ![Build a Docker image...](image)
Repository

The repository name (and optionally a tag) to be applied to the resulting image, following this pattern:

`registry.address:port/namespace/repository:tag`

Only `repository` is mandatory.

Dockerfile

Use either an existing Dockerfile (located in the working directory for the task), or specify the contents of the Dockerfile.

Do not use cache when building the image

By default, Docker will reuse a cached build during the next build. See the Docker documentation.

Select **Do not use cache...** to ensure that the new image will include changes since the last build. Note that this may incur a performance penalty.

Save the image as a file

Specify the directory location and file name. Optionally configure a **job artifact** to pass it to next stages and deployments.

If required, specify advanced options:

Environment variables

*(Optional)* Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g `JAVA_OPTS=-Xms200m -Xmx700m`).

Working sub directory

*(Optional)* An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Save your changes!

Run a Docker container

Starts a Docker container based on the specified image.

By default, the task's working directory is mounted and used as the Docker container's working directory, but you can specify your own.
settings.

By default, the container is removed on completion of the task, but you can choose **Detach container** to have the container continue to run after a deployment project completes. Containers can be linked to detached containers started by preceding tasks in a job by selecting the 'Link to detached containers' option.

Note that a non-detached container that fails to start will not be removed when the Bamboo task completes. See this [KB article](https://kb.atlassian.com) for more details.

To run a Docker container in Bamboo:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a **Task description** to help remind you why you created the task.
3. Use the **Disable this task** checkbox to control whether the task gets run.
4. Choose the **Run a Docker container** command and complete the settings. Click below to see more information about the settings:

   ![Run a Docker container](/content/Run-a-Docker-container.png)

   **Docker image**
   - The image you want to use to instantiate the Docker container

   **Detach container**
   - Allows you to run the container in the background, after a deployment project completes
   - Specify a **Container name** that isn’t used by other containers in this job.

   - Click **Add port mapping** to specify mappings that bind ports inside the container to ports on the host.

   **Wait for service to start**
   - Allows you to specify how long Bamboo should wait for the service to become available.

   - You need to specify a pattern for the URL that Bamboo should check, and a timeout period.

   **Link to detached containers**
   - Allows you to link containers to detached containers started by preceding tasks in a job.

   **Container environment variables**
   - Allows you to specify parameters to pass to the container, for example `JAVA_OPTS="-Xmx2.5G -Xms1.28G"`.

   - Separate multiple parameters with spaces. Parameters with spaces must be quoted.

   - To pass existing environment variable to a docker container do not specify its value. This way the variable with its current value will be propagated into the container’s environment.
<table>
<thead>
<tr>
<th>Container command</th>
<th>The command to run in the Docker container.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Container working directory</td>
<td>The working directory for the container.</td>
</tr>
<tr>
<td>Additional arguments</td>
<td>Additional Docker run options.</td>
</tr>
</tbody>
</table>

**Argument strings that have values which contain spaces**

You can mount additional host directories as data volumes inside the container.

If required, specify advanced options:

| Environment variables | (Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g. JAVA_OPTS="-Xms200m -Xmx700m"). |

| Working sub directory | (Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory. |

Push a Docker image to a Docker registry

Pushes a Docker image to a Docker registry. This may be the central Docker Hub registry or a custom registry.

To push a Docker repository from Bamboo to a registry:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Push a Docker image to a Docker registry command and complete the settings. Click below to see more information about the settings:
Push a Docker image to a Docker registry...

Registry
Choose to push to either Docker Hub or a custom registry.

Repository
For Docker Hub you must specify the repository name and optionally a tag, for example: namespace/repository:tag
For a custom registry you must specify the registry address, repository name and optionally a tag, for example: registry.address:port/namespace/repository:tag

Username, Password, Email
Credentials for the registry account. Leave it empty to use agents’ dockercfg file.

If required, specify advanced options:

Environment variables
(Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g JAVA_OPTS="-Xms200m -Xmx700m").

Working sub directory
(Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Save your changes!

Advanced authentication
The push task allows you to define username, password and email for authentication purposes.
If the other tasks require authentication, or if you want to share credentials between all builds for certain agents, it's possible to create the docker configuration file on the agent itself, named ~/.dockercfg:
When using the push task, leave authentication fields empty in order to use `dockercfg` instead.

Docker command updates `~/.dockercfg` file; if you have any configuration management tool in place updating this file (like puppet, chef or ansible), make sure it's not executing while you are running a docker build.

Troubleshooting

**No space left on device**

Docker stores it's images in a local image installation directory. Over time this directory may grow to consume all of the available disk space. When this occurs you should remove unused images by running the `docker rmi` command.

The following Docker issues affecting disk space may provide further information:

- Device-mapper does not release free space from removed images
- Graph deletes are non-atomic, db refs deleted without deleting on-disk entities

**Permission denied on files created within a Docker container**

Docker runs processes inside containers as the root user. This means files created on mounted volumes are owned by the root user and not by the user running the Docker command (the bamboo agent user). This may cause an issue if a subsequent task requires access to those files on the host.

Docker plans to allow mapping between container and host users in the future. Until then, you can work around this issue by changing the owner of the files in the mounted volume to the host user:

- Supply the host user's id and group id to the container by setting the following environment variables in the Docker run task configuration:
  
  - `UID`  
  - `GID`  

- Run a script inside the container to change the owner of the files in the mounted volume:

  ```bash  
  chown -R $UID:$GID /<path_to_mounted_volume>  
  ```

**Permission denied when running Docker**

When attempting to run a Docker container you may see a 'permission denied' issue:

```
2015/02/10 06:35:31 Post
http:///var/run/docker.sock/build?rm=1&t=docker-toy-demo: dial unix /
/var/run/docker.sock: permission denied
```

The solution is to add the Bamboo user agent to the Docker group on the agent.

**Getting execution errors for valid docker files or unable to start docker container**

Example build output:

```
Driver devicemapper failed to get image rootfs
511136ea3c5a64f264b78b5433614a5e5c63103b4d4702f3ba7d4d2698e22c158: Error mounting

```

Configuring the Docker task in Bamboo v6.4

The Docker task in Atlassian Bamboo allows you to use Docker images and containers in your Bamboo builds and deployments.

If you’re using a Windows Bamboo server, you can’t run Docker commands directly from the Windows command line.

To use the Docker task with a Windows Bamboo server, run Docker Machine.

The Docker task supports the following Docker actions:

- Build a Docker image
- Run a Docker container

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
• Push a Docker repository to a Docker registry

Remember to define a Docker capability on an agent before you configure a Docker task.

For examples of how to use Docker in Bamboo, see the Bamboo, Docker, and building web apps blog post.

Note that Bamboo requires Docker 1.7.1 or later. See also Getting started with Docker and Bamboo for information about how to manage and run your Bamboo remote agents using Docker.

Build a Docker image

Builds a Docker image based on the specified Dockerfile. The Dockerfile may be provided as an existing file in the task's working directory or defined in the task configuration.

The image is stored in Docker's local image installation directory and can be used by subsequent Docker tasks in the job. You can optionally save the image to a file in the working directory which can then be packaged as a build artifact.

To build a Docker image in Bamboo:

1. Create a new Docker task for the relevant job. See Configuring tasks for details.
2. Add a Task description to help remind you why you created the task.
3. Use the Disable this task checkbox to control whether the task gets run.
4. Choose the Build a Docker image command and complete the settings. Click below to see more information about the settings:

   Build a Docker image...
Repository

The repository name (and optionally a tag) to be applied to the resulting image, following this pattern:

registry.address:port/namespace/repository:tag

Only repository is mandatory.

Dockerfile

Use either an existing Dockerfile (located in the working directory for the task), or specify the contents of the Dockerfile.

Do not use cache when building the image

By default, Docker will reuse a cached build during the next build. See the Docker documentation.

Select Do not use cache... to ensure that the new image will include changes since the last build. Note that this may incur a performance penalty.

Save the image as a file

Specify the directory location and file name. Optionally configure a job artifact to pass it to next stages and deployments.

If required, specify advanced options:

Environment variables

(Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g JAVA_OPTS="-Xms200m -Xmx700m").

Working sub directory

(Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Save your changes!

Run a Docker container

Starts a Docker container based on the specified image.

By default, the task's working directory is mounted and used as the Docker container's working directory, but you can specify your own
settings.

By default, the container is removed on completion of the task, but you can choose **Detach container** to have the container continue to run after a deployment project completes. Containers can be linked to detached containers started by preceding tasks in a job by selecting the 'Link to detached containers' option.

Note that a non-detached container that fails to start will not be removed when the Bamboo task completes. See this [KB article](https://confluence.atlassian.com/) for more details.

To run a Docker container in Bamboo:

1. Create a new Docker task for the relevant job. See **Configuring tasks** for details.
2. Add a **Task description** to help remind you why you created the task.
3. Use the **Disable this task** checkbox to control whether the task gets run.
4. Choose the **Run a Docker container** command and complete the settings. Click below to see more information about the settings:

   ![Docker image](image)

   **Docker image**
   
   The image you want to use to instantiate the Docker container

   **Detach container**
   
   Allows you to run the container in the background, after a deployment project completes
   
   Specify a **Container name** that isn't used by other containers in this job.
   
   Click **Add port mapping** to specify mappings that bind ports inside the container to ports on the host.

   **Wait for service to start**
   
   Allows you to specify how long Bamboo should wait for the service to become available.
   
   You need to specify a pattern for the URL that Bamboo should check, and a timeout period.

   **Link to detached containers**
   
   Allows you to link containers to detached containers started by preceding tasks in a job.

   **Container environment variables**
   
   Allows you to specify parameters to pass to the container, for example `JAVA_OPTS=-Xmx256m -Xms128m`.
   
   Separate multiple parameters with spaces. Parameters with spaces must be quoted.

   **Container command**
   
   The command to run in the Docker container.

   **Container working directory**
### Volumes

You can mount additional host directories as data volumes inside the container.

If required, specify advanced options:

### Environment variables

(Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g. `JAVA_OPTS=-Xms200m -Xmx700m`).

### Working sub directory

(Optional) An alternative subdirectory, relative to the job's root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job's configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

**Save your changes!**

---

**Push a Docker image to a Docker registry**

Pushes a Docker image to a Docker registry. This may be the central Docker Hub registry or a custom registry.

To push a Docker repository from Bamboo to a registry:

1. Create a new **Docker** task for the relevant job. See **Configuring tasks** for details.
2. Add a **Task description** to help remind you why you created the task.
3. Use the **Disable this task** checkbox to control whether the task gets run.
4. Choose the **Push a Docker image to a Docker registry** command and complete the settings. Click below to see more information about the settings:

   Push a Docker image to a Docker registry...
Registry

Choose to push to either Docker Hub or a custom registry.

Repository

For Docker Hub you must specify the repository name and optionally a tag, for example: namespace/repository:tag. For a custom registry you must specify the registry address, repository name and optionally a tag, for example: registry.address:port/namespace/repository:tag.

Authentication type

Select how you’d like to authenticate:
- use agents’ docker.cfg file
- use username and password
- select predefined shared credentials from the drop-down list

If required, specify advanced options:

Environment variables

(Optional) Additional system environment variables that you want to pass to your build. Note that existing environment variables are automatically available to the executable. You can also include Bamboo global or build-specific variables (see Bamboo variables). Multiple variables should be separated with spaces. Parameters with spaces must be quoted (e.g JAVA_OPTS="-Xms200m -Xmx700m").

Working sub directory

(Optional) An alternative subdirectory, relative to the job’s root directory, where Bamboo will run the executable. The root directory contains everything checked out from the job’s configured source repository. If you leave this field blank, Bamboo will look for build files in the root directory. This option is useful if your task has a build script in a subdirectory and the executable needs to be run from within that subdirectory.

Save your changes!

Advanced authentication

The push task allows you to define username, password and email for authentication purposes.

If the other tasks require authentication, or if you want to share credentials between all builds for certain agents, it’s possible to create the docker configuration file on the agent itself, named ~/.dockercfg.
When using the push task, leave authentication fields empty in order to use dockercfg instead.

Docker command updates ~/.dockercfg file; if you have any configuration management tool in place updating this file (like puppet, chef or ansible), make sure it's not executing while you are running a docker build.

Troubleshooting

No space left on device

Docker stores its images in a local image installation directory. Over time this directory may grow to consume all of the available disk space. When this occurs you should remove unused images by running the `docker rmi` command.

The following Docker issues affecting disk space may provide further information:

- Device-mapper does not release free space from removed images
- Graph deletes are non-atomic, db refs deleted without deleting on-disk entities

Permission denied on files created within a Docker container

Docker runs processes inside containers as the root user. This means files created on mounted volumes are owned by the root user and not by the user running the Docker command (the bamboo agent user). This may cause an issue if a subsequent task requires access to those files on the host.

Docker plans to allow mapping between container and host users in the future. Until then, you can work around this issue by changing the owner of the files in the mounted volume to the host user:

Supply the host user’s id and group id to the container by setting the following environment variables in the Docker run task configuration:

- HOST_UID=$UID
- HOST_GID=$GID

Run a script inside the container to change the owner of the files in the mounted volume:

```
chown -R $HOST_UID:$HOST_GID /<path_to_mounted_volume>
```

Permission denied when running Docker

When attempting to run a Docker container you may see a 'permission denied' issue:

```
2015/02/10 06:35:31 Post http:///var/run/docker.sock/build?rm=1&t=docker-toy-demo: dial unix /var/run/docker.sock: permission denied
```

The solution is to add the Bamboo user agent to the Docker group on the agent.

Getting execution errors for valid docker files or unable to start docker container

Example build output:

```
Driver devicemapper failed to get image rootfs 511136ea3c5a64f264b78b5433614aec563103b4d4702f3ba7d4d2698e22c158: Error mounting

error 12-Feb-2015 12:12:14       at
If the agent consistently fails executing docker run commands, either when building an image or running an instance there is a risk that you've run into. To help diagnose this you can SSH to the agent and look at the kernel messages by running:

```bash
dmesg
```

There are several possible messages that indicate this problem. Some of those are listed here:

```
[83471099.881879] JBD2: no valid journal superblock found
[83471099.881883] EXT4-fs (dm-2): error loading journal
[88401612.723018] EXT4-fs (dm-1): warning: mounting fs with errors, running e2fsck is recommended
[88401612.724764] EXT4-fs (dm-1): mounted filesystem with ordered data mode. Opts: discard
```

There is a big risk that the device mapper is corrupt. This means that you need to stop Docker and remove the files used by devicemapper, then restart Docker. If running on an elastic agent, terminating the agent and starting a new one is also a viable option.

To stop Docker and remove the files, run the following:

```bash
sudo -i
# stop the docker daemon
service docker stop
# remove the broken devicemapper files
rm -rf /var/lib/docker
service docker start
```

The location of the devicemapper files may differ from the example above. Run the following to find the exact path:

```bash
docker info
```

Configuring a Source Control task

```
This feature is a part of the Bamboo 6.7 Early Access Program, which is are snapshots of the ongoing Bamboo development process. For that reason:

- While we try to keep these releases stable, they have not undergone the same degree of testing as a full release.
- Features in development releases maybe incomplete, or may change or be removed before the next full release.

Much as you are able to upgrade previous versions of Bamboo to the 6.7 EAP version, and smoothly upgrade from the 6.7 EAP to the final version, once it's released, we don't recommend installing the EAP release on your current production environment. For information about the supported upgrade paths, see Bamboo upgrade guide.
```
Source Control tasks allow you to quickly apply your changes to repositories. Bamboo provides support for Repository tasks in the following repositories:

- Bitbucket Cloud
- Bitbucket Server
- Git
- Mercurial

Git LFS is supported for both the commit and the push tasks.

JGit is not supported by the new tasks. They may or may not work, we give no guarantees.

It is an umbrella term for all Repository tasks available in Bamboo. Here is a list of such tasks:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="icon" alt="Repository Commit" /></td>
<td>Repository Commit</td>
<td>Available in Bamboo 6.7 and later. Task capable of committing and pushing changes to a remote repository. This task will take all modified files in repository directory, commit them with a given message, and then push them to the remote location.</td>
</tr>
<tr>
<td><img src="icon" alt="Repository Push" /></td>
<td>Repository Push</td>
<td>Available in Bamboo 6.7 and later. Task capable of committing and pushing commits to a remote repository. To be used in place of the VCS Commit task if the commits were already created and only the 'push' part is needed. The concept of 'push' only exists in DVCS repositories.</td>
</tr>
<tr>
<td><img src="icon" alt="Repository Branch" /></td>
<td>Repository Branch (previously known as: VCS Branching)</td>
<td>Task capable of creating a branch and pushing it to a remote repository. This task will create a new branch with specified name from the latest commit in the checkout directory. For Mercurial, it will create a new commit &quot;Creating branch...&quot;.</td>
</tr>
<tr>
<td><img src="icon" alt="Repository Tag" /></td>
<td>Repository Tag (previously known as: VCS Tagging)</td>
<td>Task capable of creating a tag and pushing it to a remote repository. This task will create a new tag with specified name for the latest commit in the checkout directory. For Mercurial, it will create a new commit &quot;Adding tag...&quot;.</td>
</tr>
<tr>
<td><img src="icon" alt="Source Code Checkout" /></td>
<td>Source Code Checkout</td>
<td>Task for checking out (cloning) a remote repository.</td>
</tr>
</tbody>
</table>

Configuring a Source Control task v6.7

Source Control tasks is an umbrella term for all Repository tasks available in Bamboo. Source Control tasks allow you to quickly apply your changes to repositories. Source Control tasks work in deployment and build plans and they are fully configurable using Bamboo Specs.

Bamboo provides support for Source Control tasks in the following repositories:

- Bitbucket Cloud
- Bitbucket Server
- Git

Git LFS is supported for Source Code Checkout, Repository Commit, and Repository Push tasks.
Mercurial

Here is a list of Source Control tasks available in Bamboo:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Source Code Checkout" /></td>
<td><strong>Source Code Checkout</strong></td>
<td>Task for checking out (cloning) a remote repository. You can read more about this task in Checking out code.</td>
</tr>
<tr>
<td><img src="image" alt="Repository Commit" /></td>
<td><strong>Repository Commit</strong></td>
<td>Available in Bamboo 6.7 and later. Task capable of committing and pushing changes to a remote repository. This task will take all modified files in repository directory, commit them with a given message, and then push them to the remote location.</td>
</tr>
</tbody>
</table>
| ![Repository Push](image) | **Repository Push** | Available in Bamboo 6.7 and later. Task capable of pushing commits to a remote repository. To be used in place of the VCS Commit task if the commits were already created and only the 'push' part is needed. The concept of 'push' only exists in DVCS repositories. Here are some use examples of the Repository Push task:  
- pushing commits created by other tasks over which the user has no control,  
- pushing custom commits (e.g. cryptographically signed or with a custom author),  
- pushing merge results,  
- transactional processing through your build (multiple commits with a single push at the end). |
| ![Repository Branch](image) | **Repository Branch** (previously known as: VCS Branching) | Task capable of creating a branch and pushing it to a remote repository. This task will create a new branch with specified name from the latest commit in the checkout directory. For Mercurial, it will create a new commit "Creating branch...". |
| ![Repository Tag](image) | **Repository Tag** (previously known as: VCS Tagging) | Task capable of creating a tag and pushing it to a remote repository. This task will create a new tag with specified name for the latest commit in the checkout directory. For Mercurial, it will create a new commit "Adding tag...". |

Configuring Compiler warning parser task

Use Build warnings parser tasks to scan build logs and output files for compiler warning. Warnings are aggregated into a build artifact and the summary of the warnings is displayed in the build result page.

To create a Build warnings parser task:

1. In the job configuration screen, click the **Tasks** tab.
2. Click **Add task**.
3. From the Builder type group, select **Build warnings parser**.
4. Configure the following settings:

**Task Description**
A description of the task, which is displayed in Bamboo.

**Disable this task**
Check, or clear, to selectively run this task.

**Parser**
Type of parser used by the task. Pick the one that matches the compiler (or other tools) used in previous steps of the build.

**Associate warnings with a repository**
Warnings can be associated with a repository containing your sources. This information can be later used to notify the source control system about the amount and severity of warnings found by this task. By default, the warnings are linked to the default repository of the build.

**Repository**
Pick the correct source repository to associate the warnings with.

**Input**
Where Bamboo should look for warnings. You can choose between parsing the output logs (default) or the file matching a `glob pattern`.

**Custom files**
A `glob pattern` defining which files should be scanned for compiler warnings.

**Fail build if too many warnings are found**
Switch this option if causes build to fail if number of warnings exceed defined threshold.

**Severity of warnings being counted**
The severity level of warnings counting towards build failure threshold. There are 3 severity levels: low, normal and high.

**Fail build threshold**
If number of warnings (taking into account their severity) exceeds this number the build fails.

---

**Configuring Compiler warning parser tasks v6.6**

This feature is a part of the Bamboo 6.7 Early Access Program, which is snapshots of the ongoing Bamboo development process. For that reason:

- While we try to keep these releases stable, they have not undergone the same degree of testing as a full release.
- Features in development releases maybe incomplete, or may change or be removed before the next full release.

**Example of a Build warnings parser task configuration.**

Use Compiler warning tasks to scan build logs and output files for compiler warning. Warnings are aggregated into a build artifact and the summary of the warnings is displayed in the build result page.

To create a Compiler Warning parser task:

1. In job configuration screen, click the **Tasks** tab.
2. Click **Add task**.
3. From the Builder type group, select Compiler warning parser.
4. Configure the following settings:

**Task Description**
A description of the task, which is displayed in Bamboo.

**Disable this task**
Check, or clear, to selectively run this task.

**Parser**
Type of parser used by the task. Pick the one that matches the compiler (or other tools) used in previous steps of the build.

**Associate warnings with a repository**
Warnings can be associated with a repository containing your sources. This information can be later used to notify the source control system about the amount and severity of warnings found by this task. By default, the warnings are linked to the default repository of the build.

**Repository**
Pick the correct source repository to associate the warnings with.

**Input**
Where Bamboo should look for warnings. You can choose between parsing the output logs (default) or the file matching a glob pattern.

**Custom files**
A glob pattern defining which files should be scanned for compiler warnings.

**Fail build if too many warnings are found**
Switch this option on if causes build to fail if number of warnings exceed defined threshold.

**Severity of warnings being counted**
The severity level of warnings counting towards build failure threshold. There are 3 severity levels: low, normal and high.

**Fail build threshold**
If number of warnings (taking into account their severity) exceeds this number the build fails.

### Sharing artifacts

This page describes how to keep and share artifacts produced by a job, such as reports, websites or .jar files. Bamboo allows artifact sharing between:

- Jobs
- Build plans
- Build plans to deployment environments.

**Define an artifact to keep for a job**

You can specify which artifacts to keep by setting up an artifact definition for the job. The artifacts will be available after each build of the job.

**To set up a new artifact definition:**

1. Navigate to the job, as described on Configuring jobs.
2. Click the **Artifacts** tab, and then **Create definition**:
   a. Specify a **Name** for the artifact.
   b. Use **Location** to specify the folder, relative to the build directory, where the artifact will be located. Do not use the absolute path to the artifact. Wild cards are not supported.
   c. **Copy pattern** is relative to **Location**. For example, if you want to keep the latest version of a .jar file, you could specify **Copy pattern** to be "/.jar" and the **Location** to be "target".
   d. Select the **Shared** check box if you want to share artifacts with other jobs in the plan.
3. Click **Save**.

Artifacts are copied to a subdirectory (/JOB_KEY/download-data/) under your 'Build Directory' folder – see Locating important directories and files.

### Sharing artifacts between jobs

You can share artifacts between jobs in different stages using artifact dependencies. For example, you may want to run acceptance tests on a build, sharing the same WAR from one job to another without rebuilding it each time.

Each time the artifact is shared with a subsequent job, it is copied to the job’s agent.

**To share an artifact between two jobs in different stages:**

1. Navigate to the configuration pages for the job that will produce the artifact, as described on Configuring jobs, and click the **Artifacts** tab (see Configuring a job’s build artifacts).
2. Either click Share for an existing artifact, or create a new artifact definition, as described above.
3. Navigate to the job in a subsequent stage that will consume the artifact, and click the Artifacts tab.
4. Click Create dependency, then:
   a. Choose from the Artifact list.
   b. Specify the Destination directory, then click Create.

### Edit artifact dependency

This will modify artifact dependency

- **Artifact**
  - Angry Nerds Site
    - Name of the shared artifact required by this job.
- **Destination directory**
  - target
    - The directory where the artifact will be available for your build, relative to the build's working directory.

---

1. The Artifact list only shows artifacts from jobs in previous stages that have been marked as shared. This is described in Configuring a job's build artifacts.
2. Destination directory is relative to the build directory. Do not use the absolute path to refer to the destination directory.
3. The artifact from the most recent successful build will be used. If there are no successful builds from the artifact-producing plan or the artifacts have expired, the artifact-consuming job will fail.

---

### Sharing artifacts between build plans

You can share artifacts between different build plans, however you need to use the 'Artifact downloader task' to do so. For example, you may want to run acceptance tests on a particular build from a different plan by sharing the same WAR from one plan to another without rebuilding it each time.

**To share an artifact between two build plans:**

1. Locate the build plan that you wish to associate an artifact with.
   a. Select Configure plan from the 'Actions' drop down menu.
   b. Click on Stages & jobs and select a job or create a new job if one does not already exist.
   c. Click on the Tasks tab for the selected job.
2. Click the Add task button. The 'Task types' window will appear. Select Artifact Downloader Task to open the 'Artifact downloader task' configuration pane:
Complete the configuration using the following options:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task description</td>
<td>A brief description of the artifact downloader task</td>
<td>✔️</td>
</tr>
<tr>
<td>Disable this task</td>
<td>Check this box to disable the task</td>
<td>-</td>
</tr>
<tr>
<td>Source Plan</td>
<td>The build plan that is the source of the artifact you need to download</td>
<td>✗</td>
</tr>
</tbody>
</table>

3. Click on Add another artifact to add another artifact to the download list. Alternatively, use the grey cross icon to delete an artifact from your configuration.

4. Click on Save to save your artifact download configuration.

1. The Artifact drop down menu only shows artifacts from jobs in previous stages that have been marked as shared. This is described in Configuring a job's build artifacts.

2. Destination directory is relative to the build directory. Do not use the absolute path to refer to the destination directory.

Sharing artifacts from a build plan to a deployment environment

You can also share artifacts from a build plan into a deployment environment. For example, you may wish to share a particular build result from a plan with a deployment environment. To do this, you need to add the 'Artifact downloader task' to a deployment environment during or after the environment creation process.

To share an artifact from a build plan to a deployment environment:

1. Open your deployment project and expand the relevant environment panel. In the Other settings section, click on the Tasks button. The 'Set up tasks' screen will display:

   ![Set up tasks](image)

   - Click Add task. The 'Task type' selection window will display. Select Artifact Downloader Task to open the 'Artifact downloader task configuration' pane:

2. Click Add task. The 'Task type' selection window will display. Select Artifact Downloader Task to open the 'Artifact downloader task configuration' pane:
Complete the configuration using the following options:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task description</td>
<td>A brief description of the artifact downloader task.</td>
<td>✓</td>
</tr>
<tr>
<td>Disable this task</td>
<td>Check this box to disable the task.</td>
<td>-</td>
</tr>
<tr>
<td>Artifact Name</td>
<td>Use the drop down menu to locate the name of the artifact that you want to download.</td>
<td>✗</td>
</tr>
<tr>
<td>Destination Path</td>
<td>The location of the working directory into which you want the artifact downloaded.</td>
<td>✓</td>
</tr>
</tbody>
</table>

3. Click **Add another artifact** to add another artifact to the download list.
4. Click **Save** to save your artifact download configuration.

1. The **Artifact** drop down menu only shows artifacts from jobs in previous stages that have been marked as shared. This is described in **Configuring a job's build artifacts**.
2. **Destination directory** is relative to the build directory. Do not use the absolute path to refer to the destination directory.

## Working with builds

The following pages contain information on working with your Bamboo builds:

- Working with build results
- Working with comments
- Working with labels
- Quarantining failing tests
- Setting up plan build dependencies
- Viewing test statistics for a job
- Reordering jobs in the build queue
- Stopping an active build

### Working with build results

**About builds**

A build is the execution of either a **plan** or a **job**. The execution of a plan is referred to as a 'plan build' and that of a job is a 'job build'.
### About build results

Every completed build has a **build result**:

- "Successful" — the code compiled, with or without errors, and all tests completed successfully.
- "Failed" — either the code did not compile, or at least one test failed.
- "Incomplete" — the build was not completed, e.g. it may have been stopped manually.

Additionally,

- if the build result is 'Failed', and the previous build result was 'Successful', the build is said to be 'Broken'.
- if the build result is 'Successful', and the previous build result was 'Failed', the build is said to be 'Fixed'.

The latest build result for every plan is listed on the Dashboard. Bamboo can also send notifications and generate RSS feeds about build results.

### Viewing a build result

The instructions on this page describe how to view the build results for a plan.

Every completed build has a **build result**:

- "Successful" — the code compiled, with or without errors, and all tests completed successfully.
- "Failed" — either the code did not compile, or at least one test failed.
- "Incomplete" — the build was not completed, e.g. it may have been stopped manually.

Additionally,

- if the build result is 'Failed', and the previous build result was 'Successful', the build is said to be 'Broken'.
- if the build result is 'Successful', and the previous build result was 'Failed', the build is said to be 'Fixed'.

### Viewing the most recent build result for a plan

To view the most recent job build result of a plan:

1. Click **Dashboard** in the top menu.
2. Locate the plan on the **All Plans** tab, then click the build number.

---

**On this page:**

- Viewing the most recent build result for a plan
- Viewing all build results for a plan
- Viewing all build results for a job

</tbody>
</table>
Tests | Provides details of the build's test results.
---|---
Changes | Provides details of the code changes that triggered this build (if applicable).
Artifacts | Shows any artifacts relating to this build.
Logs | Displays a complete build log.
Metadata | Displays any metadata that relates to this build.
Build Times | Displays a histogram of build times for jobs, and a list of which agents were used to build each job.
Issues | Provides details of the Jira issues linked to this build (if applicable). Availability depends on Bamboo's configuration.
Clover | Displays the Clover code-coverage that relates to this build (if applicable). The clover tab is located on the job level because a build can have more than one jobs, and each job might have different Clover results or not have clover tab at all. That's why in order to see the Clover tab, you need to drill down to the individual job that contains the clover report.

- You can assign responsibility for a broken build, either to yourself (click **Claim full responsibility**) or to someone else in your team (click **Assign responsibility**).

**Viewing all build results for a plan**

To view all build results for a plan:

1. Click **Dashboard** in the top menu.
2. Click the plan on the **All Plans** tab. The ten most recent builds will be displayed in the 'Recent History' section on the **Plan Summary** tab. See **Viewing a plan's build information**.
3. Click the **History** tab to view all builds for the plan.

**Viewing all build results for a job**

To view all build results for a job:

1. Navigate to the desired job, as described on **Configuring jobs**. The ten most recent builds will be displayed in the 'Recent History' section of the **Job Summary** tab.
2. Click the **History** tab to view all builds for the job.

**Viewing test results for a build**

Bamboo provides a convenient summary of all the tests that were run when a particular build was executed — as well as full details of any errors. This is useful when you are investigating what caused a build to fail.

Note that for more meaningful display of test names within Bamboo, the word 'test' is stripped out of test case name names if it occurs at the beginning, and capitals and underscores are treated as word separators.

**Related pages:**
- Viewing a test's history

**To view the test results for a particular build:**

1. Navigate to the build results for the plan or job, as described in **Viewing a build result**, and click the desired build result.
2. Click the **Tests** tab.
   - Click the test name to see a particular test's results for other builds.

**Screenshot: Test results for a build**
1. Viewing a test's history

A test's history shows you:

- The occasions when the test has failed. This can be useful when investigating what code changes were related to a failed test (see below).
- The test's average duration (running time), and whether the duration is increasing or decreasing across builds.

**Related pages:**

- Viewing test results for a build

**To view a test's history:**

1. Navigate to the build results for the Plan/Job, as described in Viewing a build result, and click the desired build result.
2. Click the Tests tab.
3. Click the name of the test in which you are interested. The test's latest result will be displayed.
4. Click View test case across builds. The 'Test History' will be displayed, as shown below.

**Screenshot: Test History**
Viewing the code changes that triggered a build

If a build was triggered by a code change, the updated files will be listed in the build result.

When Atlassian's Fisheye is connected to your Bamboo server, you can view the code changes that triggered a build. When a build fails due to a compilation error or failed test, you can explore the failed build in Fisheye and jump directly into the changeset that broke the build. You can view the history of that changeset to see what the author was trying to fix, take advantage of the side-by-side diff view to analyze the change and then open the correct files in your IDE.

**Related pages:**
- Linking to source code repositories
- Triggering builds

To view the code changes that triggered a particular build result:

1. Navigate to the build results for the plan, as described in Viewing a build result, and click the desired build result.
2. Click the Changes tab. A list of updated files will be shown.
   - Click the link to the source file to view the changes.
   - Click the version number to view the entire file.
   - Click the diffs link to view the differences between the current and previous version of each file.

Links to individual source-code files will only be available if your Bamboo administrator has connected the plan to the source repository, as specified in the 'Advanced Options' on the 'Source Repositories' tab for the plan. For details, see Integrating Bamboo with Fisheye.

Viewing a build's artifacts

After a build has run, you can view the artifacts that were produced by all of the jobs in the plan. You can also view the latest version of an artifact from the most recent build.

*Artifacts* are files created by a job build (e.g. JAR files). Artifact definitions are used to specify which artifacts to keep from a build and are configured for individual jobs.

Viewing the artifacts for a build

To view a build's artifacts:

1. Go to the build result. See Viewing a build result for instructions.
2. Click the Artifacts tab. The artifacts produced by the jobs in the plan will be displayed. The artifact definitions for a job determine which artifacts are kept and which artifacts are shared with other jobs in the plan.

**On this page:**
- Viewing the artifacts for a build
- Viewing the latest version of an artifact from the latest build

**Related pages:**
- Configuring a job's build artifacts
- Sharing artifacts

Viewing the latest version of an artifact from the latest build
To view the latest version of an artifact from the most recent build, you can manually edit the build artifact URL to retrieve it.

To view the latest version of an artifact from the most recent build:

1. Copy the URL for the build artifact.
2. Paste the URL for the build artifact in your browser and replace the build number in the URL with '/latest'.
   - If you need to log in to view the artifacts, you can append os_username and os_password parameters to the URL to access the files.

For example, if the URL for your artifact is:
http://server/bamboo/browse/MYBUILD-254/artifact/logs/sample-log.log
You would replace '-254' with /latest:
http://server/bamboo/browse/MYBUILD/latest/artifact/logs/sample-log.log

Artifacts
The following artifacts have been generated by the jobs in this plan.

Shared artifacts
You can share artifacts between jobs in different stages via artifact dependencies. Each time the artifact is shared with a subsequent job, it is copied to the job's agent.

<table>
<thead>
<tr>

Viewing a build log
Every build has a build log. A build log is a permanent record of all the output generated by compiling the job's source-code and executing the tests.

Related pages:
- Working with build results

To view a build log:

1. Navigate to the build results for the plan or job, as described in Viewing a build result, and click the desired build result.
2. Click the Logstab.
   - Click View for the desired log.
   - Click Download to download a text file of the log.

Screenshot: Build Log
Viewing the metadata for a build result

If your source-code repository provides metadata (i.e. key-value properties that are used to describe your build) for your build results, Bamboo will display it.

To view the metadata for a build result:

1. Navigate to the build results for the plan or job, as described in Viewing a build result, and click the desired build result.
2. Click the Metadata tab.

Screenshot: Metadata for a Build Result

The instructions on this page describe how to view the build results for a plan.
Every completed build has a **build result**:

- "Successful" — the code compiled, with or without errors, and all tests completed successfully.
- "Failed" — either the code did not compile, or at least one test failed.
- "Incomplete" — the build was not completed, e.g. it may have been stopped manually.

Additionally,

- if the build result is 'Failed', and the previous build result was 'Successful', the build is said to be 'Broken'.
- if the build result is 'Successful', and the previous build result was 'Failed', the build is said to be 'Fixed'.

### Viewing the most recent build result for a plan

**To view the most recent job build result of a plan:**

1. Click **Dashboard** in the top menu.
2. Locate the plan on the **All Plans** tab, then click the build number.

**On this page:**

- Viewing the most recent build result for a plan
- Viewing all build results for a plan
- Viewing all build results for a job

</table>

- You can assign responsibility for a broken build, either to yourself (click Claim full responsibility) or to someone else in your team (click Assign responsibility).

**Viewing all build results for a plan**

**To view all build results for a plan:**

1. Click Dashboard in the top menu.
2. Click the plan on the All Plans tab. The ten most recent builds will be displayed in the 'Recent History' section on the Plan Summary tab. See Viewing a plan's build information.
3. Click the History tab to view all builds for the plan.

**Viewing all build results for a job**

**To view all build results for a job:**

1. Navigate to the desired job, as described on Configuring jobs. The ten most recent builds will be displayed in the 'Recent History' section of the Job Summary tab.
2. Click the History tab to view all builds for the job.

**Assigning responsibility for build failures**

Bamboo automatically alerts the people who are assigned as responsible for a broken build, and lets other members of the team know that someone is looking at the problem. As you investigate the build failure, you can revise who is responsible, or claim all the responsibility for yourself!

**People are assigned as being responsible for fixing a broken build in two ways:**

- When a build fails, Bamboo automatically assigns all those who committed code to the failing build as responsible.
- You can manually assign people as being responsible.

Bamboo then sends notifications to whoever is assigned. Once the build is successful, Bamboo removes the responsible people from the build – they're off the hook!

**Note that notifications need to have been configured first, using the 'Change of Responsibilities' Event and the 'Responsible User' Recipient Type. See Configuring notifications for a plan and its jobs for more information.**

**Related pages:**

- Working with build results
- Working with comments
- Notifications

**To assign responsibility for a broken build manually:**

1. Go to the Build Result Summary for a plan.
2. Click Assign responsibility to make another member of your team responsible for fixing the build.
3. Click Claim full responsibility if you want to shoulder all the blame yourself.

People who are responsible for the broken build are displayed on the Build Result Summary.

Broken builds that are assigned to you are displayed on your My Bamboo page, available from the Dashboard.
Configuring build results expiry for a plan

By enabling build expiry for a particular plan (described below), you override the global expiry settings that affect all plans in Bamboo. If you disable build expiry for a plan, that plan's build result data will never be automatically deleted from your Bamboo server.

You can choose the build result data that will be kept for a plan and for how long this data will be kept (e.g. for reporting purposes), before Bamboo automatically deletes it.

Note that the build expiry event is a global event that runs periodically, regardless of whether you disable or enable build expiry in your plans. When this event occurs, the build results for your plan will be expired according to the settings below, or globally. To configure the global event and global build expiry settings, please refer to Configuring global expiry.

You can also delete the results of a plan build manually — see Deleting the results of a plan build.

**Configure the expiry of build results for a plan**

Ensure that you back up your build results data before its expiry date is reached.

Configure build expiry as follows:

1. Navigate to the configuration for the desired plan, as described on Configuring plans.
2. Click the Miscellaneous tab.
3. Select the Override global build expiry configuration checkbox. Configure expiry using the following settings:
   
   **Do not expire anything for this plan**
   Select to disable expiry for all build results and artifacts for this plan – these will never be deleted automatically.

   **Build results**
   All build results data (including artifacts and build logs) are deleted.

   **Build artifacts**
   Only user-defined artifacts are deleted from the build results.

   **Build logs**
   Only build logs are deleted from the build results.

   **Expiry after**
   Specifies the period (days, weeks or months) for which you want to keep build results.
   E.g. specify '24 months' to keep all build results for the last two years.

   **Minimum builds to keep**
   Specifies the minimum number of build results you want to keep.
   For example, specify '50' to keep the latest 50 build results, even if they are older than the period specified with Expiry period.

   **Keep builds with the following labels**
   Specifies the build labels (not plan labels or job labels) applied to builds for which you want to keep build results, regardless of the Expiry period and Minimum builds to keep settings. Note that builds can be labeled either manually or automatically.

4. Click Save.

**Screenshot: Configuring build expiry**
Configuring build results expiry for a plan v5.14

By enabling build expiry for a particular plan (described below), you override the global expiry settings that affect all plans in Bamboo. If you disable build expiry for a plan, that plan’s build result data will never be automatically deleted from your Bamboo server.

You can choose the build result data that will be kept for a plan and for how long this data will be kept (e.g. for reporting purposes), before Bamboo automatically deletes it.

Note that the build expiry event is a global event that runs periodically, regardless of whether you disable or enable build expiry in your plans. When this event occurs, the build results for your plan will be expired according to the settings below, or globally. To configure the global event and global build expiry settings, please refer to Configuring global expiry.

You can also delete the results of a plan build manually — see Deleting the results of a plan build.

Configure the expiry of build results for a plan

Ensure that you back up your build results data before its expiry date is reached.

Configure build expiry as follows:

1. Navigate to the configuration for the desired plan, as described on Configuring plans.
2. Click the Miscellaneous tab.
3. Select the Override global build expiry configuration checkbox. Configure expiry using the following settings:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

---

**Deleting the results of a plan build**

If the results of a plan builds are no longer required, you can completely remove them from your Bamboo system. The results include all the results of all job builds that were processed as part of an individual plan build (with a specific build number). Note that you can also remove job build result data that reaches a particular age. See Configuring global expiry or Configuring expiry of a plan’s job build results for more information.

**Related pages:**
- 2018-02-07_10-47-50_Deleting a job’s current working files

Before you begin:
- The ‘Admin’ global permission or ‘Admin’ plan permission is required to delete plan build results.
- The result of a plan build cannot be deleted if that plan is currently being built. If you need to delete the result of a plan build, stop the plan’s build first. Refer to Stopping an active job build for more information.

**To delete the result of a plan build:**
1. Click Dashboard and then the All Plans tab.
2. In the list of plans, click the name of the desired plan.
3. Click the History tab. A table of completed plan build results will be displayed, with the most recent builds at the top.
4. Locate the desired build result and click Delete. (see screenshot below).
5. Confirm the deletion. The plan build result and any artifacts generated as a result of the plan build’s execution will be deleted.

Working with comments

Comments are a useful way to record and share information about builds. There are two types of comments in Bamboo:
- Comments you make about a build result — these are comments that you make about a particular build result.
• Comments you make when you commit code — these comments are automatically copied into Bamboo from your source-code repository.

When you include Jira issue keys in your build and commit comments, Bamboo will automatically convert these into hyperlinks to the respective Jira issues, if Bamboo is integrated with Jira. The issue key must be of the default Jira issue key format (that is, two or more uppercase letters \([A-Z]\{2\} [A-Z]+\), followed by a hyphen and the issue number, for example BAM-123).

Comment on a build result

When you are logged in to Bamboo, you can comment on a build result to record relevant information for future reference, and to collaborate with your team. You can see other’s comments there too, of course.

Simply navigate to a build result and enter your comment on the 'Build summary' tab:

![Build result summary](image)

Commit comments

If a build was triggered by a code change, the commit comment (or check-in comment) will be shown on the ‘Build summary’ tab of the build result:

![Commit comments](image)

You can see more details of the commit on the Commits tab of the build summary.

Working with labels

A label is a convenient way to tag and group build results that are logically related to each other. Labels can also be used to define RSS feeds and to control build expiry. With Bamboo, you can label your build results in whatever way works best for your team. Labels are not restricted to a particular plan, so you can apply the same label to build results from different plans.

For example, it might not be practical for your QA team to review every build, and you need to know which builds they have reviewed. By using labels such as “qa_passed” and “qa_failed”, Bamboo allows them to simply indicate which builds have passed and failed QA.

You can include Jira a issue key in the label, as long as the key is of the default Jira issue key format (that is, two or more uppercase letters \([A-Z]\{2\} [A-Z]+\), followed by a hyphen and the issue number, for example BAM-123).

Bamboo administrators can also configure automatic labeling of job build results.

Label a build result

You must be logged in to Bamboo before you can label a build result.
To label a particular build result, simply click the pencil icon ( ), beside Labels in the 'Details' section of the 'Build summary' tab. You can also label a build result using Instant Messaging. Click the ‘x’ at the right of a label if you need to remove it.

Click Labels on the 'Build summary' tab to see the other labels that have been used for the plan's builds. Click a label there to see all the projects, plans and build results where that label is used.

Label a plan

Bamboo allows you to label plans. Labeling a plan allows you to filter the plans displayed on the Dashboard or Wallboard. You may want to do this if you have set up a large number of plans in your Bamboo instance and want to highlight specific plans for attention.

For example, you may want to label all builds related to the release with a 'release' label. You can then filter your wallboard during your release, to display only these builds.

You must be logged in to Bamboo before you can label a plan.

Simply go to the plan you want to label and choose Actions > Modify plan label.

Quarantining failing tests

There may be times when you want to prevent a failing test from causing the whole build to fail.

Possible scenarios where this may be useful include:
  - You want to build an artifact despite there being a failing test, but can't do this while the plan build is failing.
  - In test-driven development (TDD), a test will fail until the functionality is implemented - you want to quarantine all but the relevant tests.
  - A test may give unpredictable results, perhaps because of infrastructure issues or dependencies.
  - You want to remove a test from a build, but don't want to alter or delete the test source code because doing so could affect another Bamboo plan.

In Bamboo, you can temporarily disconnect any test's results from the plan build results by quarantining the test. The test is still run whenever the plan is built, but the test's results do not affect the plan's build results.

You can always restore a test's results to the build results when required, for example if the test is now passing.

All the quarantined tests for a plan are displayed on the Quarantined Tests tab of the plan summary. The status bar for each test shows the recent build history of the test.

On this page:
  - To quarantine a failing test
  - To restore a quarantined test to a build

To quarantine a failing test

You need plan administrator permission to quarantine a test.

1. Choose Dashboard > All Plans > #buildresult to go to the build result where the test is failing.
2. Click Quarantine for the failing test (in the 'Build Result Summary' screen).

To restore a quarantined test to a build

You need plan administrator permission to restore a test.

1. Choose Dashboard and click on a plan to go to the plan's summary.
2. Click the Quarantined Tests tab.
3. Click Unleash for the test to be restored.

Screenshot: The quarantined tests for a plan, showing the Status bar.
Quarantining failing tests v5.14

There may be times when you want to prevent a failing test from causing the whole build to fail.

Possible scenarios where this may be useful include:

- You want to build an artifact despite there being a failing test, but can't do this while the plan build is failing.
- In test-driven development (TDD), a test will fail until the functionality is implemented - you want to quarantine all but the relevant tests.
- A test may give unpredictable results, perhaps because of infrastructure issues or dependencies.
- You want to remove a test from a build, but don't want to alter or delete the test source code because doing so could affect another Bamboo plan.

In Bamboo, you can temporarily disconnect any test's results from the plan build results by quarantining the test. The test is still run whenever the plan is built, but the test's results do not affect the plan's build results.

You can always restore a test's results to the build results when required, for example if the test is now passing.

All the quarantined tests for a plan are displayed on the Quarantined Tests tab of the plan summary. The status bar for each test shows the recent build history of the test.

To quarantine a failing test

You need plan administrator or build permission to quarantine a test.

1. Choose Dashboard > All Plans > #buildresult to go to the build result where the test is failing.
2. Click Quarantine for the failing test (in the 'Build Result Summary' screen).

To restore a quarantined test to a build

You need plan administrator permission to restore a test.

1. Choose Dashboard and click on a plan to go to the plan's summary.
2. Click the Quarantined Tests tab.
3. Click Unleash for the test to be restored.

Screenshot: The quarantined tests for a plan, showing the Status bar.
Setting up plan build dependencies
You may want to trigger a plan build when another plan’s build has successfully completed. This ensures that changes to any job's source code associated with one plan does not break the build of another dependent plan (known in this context as a 'child' plan).

For example, there could be two plans in Bamboo:

1. Acme – Core — which contains the core code for an application.
2. Acme – Plugin — which contains code for a plugin to the application.

In this scenario, the Acme – Plugin plan is a child of Acme – Core. Any changes to source code associated with the Acme – Core plan should trigger a build of Acme – Plugin.

To trigger a child plan to build when this plan builds successfully:
1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon to display the plan's Configuration pages.
3. Click the Dependencies tab.
4. Under 'Child Plans', begin typing a plan name in Search for plan to select child plans to trigger. You can set multiple plans to be triggered.
5. Click Save.

Automatic dependency management with Maven 3

Automatic Dependency Management is a feature for users who use Maven 3 and wish for their parent and child dependencies to be set up according to the dependencies in the Maven pom.xml. Every time the plan is run, the Bamboo Automatic Dependencies are updated to reflect any additions or removals of Maven dependencies.

To setup automatic dependency management:
1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon to display the plan's configuration pages.
3. Locate the job that contains the pom.xml you wish to use to automatically update plan dependencies by analyzing a Maven pom file.
5. Click on the Tasks tab.
6. Click Add Task and add the Maven Dependency Processor task to the job. For best results, ensure that the task runs last by dragging it to the bottom of the task list. For more information on configuring tasks, see Configuring tasks.

Override Project File
Optional. The location relative to the working directory or sub-working directory where the project file (pom.xml) is located.

Working Sub Directory
Optional. The sub directory from which the Task should look for the project file (pom.xml)

Alternate location of settings.xml
Optional. Specify an alternate settings.xml to be used if the Task needs to resolve dependencies from specific Maven repositories.

Path to Maven local repository
Optional. Specify a full path to a local Maven repository for the Task to use to resolve dependencies.

7. Click Save.
8. Use the Plan Navigator to return to the plan.
9. Click the Dependencies tab.
10. Select Automatic Dependency Management. You should see the name of the job for which you configured the Maven Dependency Processor appear.
11. Click Save.

Dependency blocking

Dependency blocking is an advanced feature of dependent build triggering that can be used to manage plan builds with parent build dependencies. This ensures that a “tree” of dependent builds always runs in tree hierarchy order, even if child plan builds are triggered independently of their parents. For more information, see Dependency blocking strategies. Please note, dependency blocking only works when the plan build is triggered because of source repository code updates.

Notes

Build dependencies work together with the trigger configuration of plans to trigger builds of these plans. For example, you can set up Plan A to poll its repository for changes as well as to be dependent on a parent plan (Plan B). In this case, builds of Plan A will be triggered when code changes are detected in its repository and also when builds of Plan B complete successfully.

If you want your builds to only be triggered by successful parent builds from your build dependencies, don’t configure triggering for your child plans at all. See Running a plan build manually.

- If the child build uses the same source as the parent build (for example, the Subversion URL is the same), the child build will be forced to check out the same revision of source code as the parent build. This ensures that builds are consistent when triggering one build from another.
- Take care not to create circular dependencies, where your child build triggers one of its parent builds. Otherwise your plans may build continuously. See Running a plan build manually.

Dependency blocking strategies

Dependency blocking is an advanced feature of dependent build triggering that can be used to manage the builds of plans that have parent plans. This ensures that a ‘tree’ of dependent builds always runs in tree hierarchy order, even if child plan builds are triggered independently of their parents.

The three dependency blocking strategies are:

Do not block
When triggered by a source code update, the plan will always be built, regardless of any parent plan build dependencies.

Block build if parent builds are queued or in progress
When triggered by a source code update, the plan will not be built if its parent plans are building or are waiting in the build queue.

Block build if parent plans have unbuilt changes
When triggered by a source code update, the plan will not be built if its parent plans are building, are waiting in the build queue, or have changes.

When Bamboo finds parent plans with source repository changes, those plans will be triggered and your plan will be blocked.

Note that for the Block build if parent plans have unbuilt changes option, only the repositories of parent plans that are specified by triggers (that is, by the Polling the repository for changes or Repository triggers the build when changes are committed trigger types) are scanned for unbuilt changes; if there are repository changes (for parent plans), then the parent plans are triggered and the current plan is blocked.

⚠️ Dependency blocking only works when the plan uses a trigger configuration based on source code updates (i.e. Polling the repository for changes or Repository triggers the build when changes are committed). This feature will not work when a plan uses a trigger configuration based on a schedule or triggered via a parent build (when there are multiple parent plan builds in progress).

These dependency blocking strategies are illustrated in the flowchart below:
Dependency blocking strategies v5.14

Dependency blocking is an advanced feature of dependent build triggering that can be used to manage the builds of plans that have parent plans. This ensures that a 'tree' of dependent builds always runs in tree hierarchy order, even if child plan builds are triggered independently of their parents.

The three dependency blocking strategies are:

<table>
<thead>
<tr>
<th>Strategy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not block</td>
<td>When triggered by a source code update, the plan will always be built, regardless of any parent plan build dependencies.</td>
</tr>
<tr>
<td>Block build if parent builds are queued or in progress</td>
<td>When triggered by a source code update, the plan will not be built if its parent plans are building or are waiting in the build queue.</td>
</tr>
<tr>
<td>Block build if parent plans have unbuilt changes</td>
<td>When triggered by a source code update, the plan will not be built if its parent plans are building, are waiting in the build queue, or have changes. When Bamboo finds parent plans with source repository changes, those plans will be triggered and your plan will be blocked.</td>
</tr>
</tbody>
</table>

Note that for the Block build if parent plans have unbuilt changes option, only the repositories of parent plans that are specified by triggers (that is, by the Polling the repository for changes or Repository triggers the build when changes are committed trigger types) are scanned for unbuilt changes; if there are repository changes (for parent plans), then the parent plans are triggered and the current plan is blocked.

Dependency blocking only works when the plan uses a trigger configuration based on source code updates (i.e. Polling the repository for changes or Repository triggers the build when changes are committed). This feature will not work when a plan uses a trigger configuration based on a schedule or triggered via a parent build (when there are multiple parent plan builds in progress).

These dependence blocking strategies are illustrated in the flowchart below:
Dependency blocking is an advanced feature of dependent build triggering that can be used to manage the builds of plans that have parent plans. This ensures that a 'tree' of dependent builds always runs in tree hierarchy order, even if child plan builds are triggered independently of their parents.

The three dependency blocking strategies are:

- **Do not block**
  When triggered by a source code update, the plan will always be built, regardless of any parent plan build dependencies.

- **Block build if parent builds are queued or in progress**
  When triggered by a source code update, the plan will not be built if its parent plans are building or are waiting in the build queue.

- **Block build if parent plans have unbuilt changes**
  When triggered by a source code update, the plan will not be built if its parent plans are building, are waiting in the build queue, or have changes.

When Bamboo finds parent plans with source repository changes, those plans will be triggered and your plan will be blocked.

Note that for the Block build if parent plans have unbuilt changes option, only the repositories of parent plans that are specified by triggers (that is, by the Polling the repository for changes or Repository triggers the build when changes are committed trigger types) are scanned for unbuilt changes; if there are repository changes (for parent plans), then the parent plans are triggered and the current plan is blocked.

Dependency blocking only works when the plan uses a trigger configuration based on source code updates (i.e. Polling the repository for changes or Repository triggers the build when changes are committed). This feature will not work when a plan uses a trigger configuration based on a schedule or triggered via a parent build (when there are multiple parent plan builds in progress).

These dependence blocking strategies are illustrated in the flowchart below:

Setting up plan build dependencies v6.1

You may want to trigger a plan build when another plan's build has successfully completed. This ensures that changes to any job's source code associated with one plan does not break the build of another dependent plan (known in this context as a 'child' plan).

For example, there could be two plans in Bamboo:

1. **Acme – Core** — which contains the core code for an application.
2. **Acme – Plugin** — which contains code for a plugin to the application.

In this scenario, the Acme – Plugin plan is a child of Acme – Core. Any changes to source code associated with the Acme – Core plan should trigger a build of Acme – Plugin.

- Notes

#### Triggering dependent plans

To trigger a child plan to build when this plan builds successfully:

1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon to display the plan's Configuration pages.
3. Click the Dependencies tab
4. Under ‘Child Plans’, begin typing a plan name in Search for plan to select child plans to trigger. You can set multiple plans to be triggered.
5. Click Save.

**Automatic dependency management with Maven 3**

Automatic Dependency Management is a feature for users who use Maven 3 and wish for their parent and child dependencies to be set up according to the dependencies in the Maven pom.xml. Every time the plan is run, the Bamboo Automatic Dependencies are updated to reflect any additions or removals of Maven dependencies.

**To setup automatic dependency management:**

1. Click Dashboard and then the All Plans tab.
2. Locate the plan in the list and click the edit icon to display the plan’s configuration pages.
3. Locate the job that contains the pom.xml you wish to use to automatically update plan dependencies by analyzing a Maven pom file.
5. Click on the Tasks tab.
6. Click Add Task and add the Maven Dependency Processor task to the job. For best results, ensure that the task runs last by dragging it to the bottom of the task list. For more information on configuring tasks, see Configuring tasks.

**Override Project File**
Optional. The location relative to the working directory or sub-working directory where the project file (pom.xml) is located.

**Working Sub Directory**
Optional. The sub directory from which the Task should look for the project file (pom.xml)

**Alternate location of settings.xml**
Optional. Specify an alternate settings.xml to be used if the Task needs to resolve dependencies from specific Maven repositories.

**Path to Maven local repository**
Optional. Specify a full path to a local Maven repository for the Task to use to resolve dependencies.
7. Click Save.
8. Use the Plan Navigator to return to the plan.
9. Click the Dependencies tab.
10. Select Automatic Dependency Management. You should see the name of the job for which you configured the Maven Dependency Processor appear.
11. Click Save.

**Dependency blocking**

Dependency blocking is an advanced feature of dependent build triggering that can be used to manage plan builds with parent build dependencies. This ensures that a “tree” of dependent builds always runs in tree hierarchy order, even if child plan builds are triggered independently of their parents. For more information, see Dependency blocking strategies. Please note, dependency blocking only works when the plan build is triggered because of source repository code updates.

**Notes**

Build dependencies work together with the trigger configuration of plans to trigger builds of these plans. For example, you can set up Plan A to poll its repository for changes as well as to be dependent on a parent plan (Plan B). In this case, builds of Plan A will be triggered when code changes are detected in its repository and also when builds of Plan B complete successfully. If you want your builds to only be triggered by successful parent builds from your build dependencies, don’t configure triggering for your child plans at all. See Running a plan build manually.

- If the child build uses the same source as the parent build (for example, the Subversion URL is the same), the child build will be forced to check out the same revision of source code as the parent build. This ensures that builds are consistent when triggering one build from another.
- Take care not to create circular dependencies, where your child build triggers one of its parent builds. Otherwise your plans may build continuously. See Running a plan build manually.

**Setting up plan build dependencies v5.14**

You may want to trigger a plan build when another plan’s build has successfully completed. This ensures that changes to any job’s source code associated with one plan does not break the build of another dependent plan (known in this context as a ‘child’ plan).

For example, there could be two plans in Bamboo:

1. Acme – Core — which contains the core code for an application.
2. Acme – Plugin — which contains code for a plugin to the application.

In this scenario, the Acme – Plugin plan is a child of Acme – Core. Any changes to source code associated with the Acme – Core plan should trigger a build of Acme – Plugin.

</tbody>
</table>

7. Click **Save**.
8. Use the Plan Navigator to return to the plan.
9. Click the **Dependencies** tab.
10. Select **Automatic Dependency Management**. You should see the name of the job for which you configured the **Maven Dependency Processor** appear.
11. Click **Save**.

### Dependency blocking

Dependency blocking is an advanced feature of dependent build triggering that can be used to manage plan builds with parent build dependencies. This ensures that a "tree" of dependent builds always runs in tree hierarchy order, even if child plan builds are triggered independently of their parents. For more information, see **Dependency blocking strategies**. Please note, dependency blocking only works when the plan build is triggered because of source repository code updates.

### Notes

Build dependencies work together with the trigger configuration of plans to trigger builds of these plans. For example, you can set up Plan A to **poll its repository for changes** as well as to be dependent on a parent plan (Plan B). In this case, builds of Plan A will be triggered when code changes are detected in its repository and **also when** builds of Plan B complete successfully.

If you want your builds to **only** be triggered by successful parent builds from your build dependencies, don't configure triggering for your child plans at all. See **Running a plan build manually**.

- If the child build **uses the same source** as the parent build (for example, the Subversion URL is the same), the child build will be forced to check out the same revision of source code as the parent build. This ensures that builds are consistent when triggering one build from another.
- Take care not to create **circular dependencies**, where your child build triggers one of its parent builds. Otherwise your plans may build continuously. See **Running a plan build manually**.

### Viewing test statistics for a job

Bamboo provides a summary of test results across all of a job's builds. This helps you to:

- **Troubleshoot** by identifying which tests fail most frequently, and which tests take longest to fix.
- **Manage your build duration** by identifying the plan's slowest running tests.
- **Ensure quality** by monitoring the number of tests over time: are your test cases growing with your code base?
To view the test statistics for all of a job's builds:

1. Navigate to the desired build result page, as described in Viewing a build result.
2. Click the Tests tab.
3. Click the sub-tabs to filter the rest statistics (see screenshots below).
   - To view a test's history, click the test name.

**Screenshot: Test statistics for a job**

<table>
<thead>
<tr>
<th>Test</th>
<th>Time broken</th>
<th>Job</th>
<th>Most recent builds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Reordering jobs in the build queue**

Bamboo automatically assigns a plan's jobs to the build queue when the plan is triggered and no agents are available to run them. The build queue is displayed on the Build Activity tab of the Dashboard.

If you want to prioritize one job build over another in the build queue, you can manually reorder these jobs in the build queue. This will not force a job build to run immediately, but will promote it in the build queue. Your job build will still require an agent (which has the capabilities to meet the job's requirements) to become available. Similarly, you can demote a job build in the build queue if you do not need it to run urgently.

Bamboo administrators can reorder plans in the queue. To do this, use the icon to move the plan to its new position in the queue.

**Stopping an active build**

The instructions on this page describe how to stop a plan or job build that is running.

Note that if your Bamboo server runs on Windows, it may only be possible to stop an active build by going to the Windows Task Manager and ending the relevant processes.

To start a building a plan manually, see Running a plan build manually.
Stopping an active plan build

To prevent Bamboo submitting a plan to the build queue, refer to Disabling or deleting a plan.

To stop an active plan build:
1. Click Dashboard and then the All Plans tab.
2. Click the ‘Stop’ icon next to the active plan you want to stop.

Stopping an active job build

To prevent Bamboo submitting a job to the build queue, refer to Disabling or deleting a job.

To stop an active job build:
1. Click Dashboard and then the All Plans tab.
2. Click the name of the plan.
3. Click the ‘Stop’ icon next to the active job you want to stop (in the ‘Current Activity’ section).

Deployment projects

What are deployment projects?

A deployment project in Bamboo is a container for holding the software project you are deploying: releases that have been built and tested, and the environments to which releases are deployed. Teams typically have QA, staging and production environments.

Why use deployment projects?

Continuous Integration was not designed for Continuous Delivery. Continuous Integration is designed to keep developers informed about the state of the latest code changes.

In Continuous Integration, historical build results (along with information such as issue and commits) are de-emphasized as more changes are made, since only the latest build is important to the developer.

Using a traditional Continuous Integration server for Continuous Delivery is less than ideal because:

- **Deployed builds are difficult to find** – Builds that were deployed only a few days ago are de-emphasized by the system. While this is good for a Continuous Integration workflow, the behavior makes it difficult for team members to identify which builds have been deployed and when, versus which have not. Teams can work around this with a system that uses labeling but it’s not immediately obvious how it should work unless team members are trained to use it correctly.
- **Difficult to find what changes were made between deployments** – Build results report commit and issue data between a specific build result and the one immediately before it. There can be many build results between two different deployments. Often the entire history has to be navigated between the two deployments to build a complete view of the changes between them. Sometimes, even other tools have to be used, such as version control systems.

- **Difficult to know what was deployed, and when and where it was deployed** – Builds do not have visibility of where code is deployed or what was previously deployed to an environment.
- **Lack of insight into the QA process** – Given a list of deployment candidates, builds offer no clear way (other than commenting or labeling) for QA to ‘sign off’ on a tested release or mark a release as broken or unreleasable.
- **Poor control over who can deploy** – While it can be controlled by permissions who can run, view or edit a build, they do not give enough fine grained control over which people in the team can deploy to production or other sensitive environments. In essence, if someone has permission to run the build they can deploy the software any time they wish.

To solve these issues Bamboo provides the following concepts:

- **Deployment project** – Represents the software you are deploying (such as a web application), the releases of the software deployed and the environments that they will be deployed to throughout the lifecycle.
- **Environment** – Represents the servers or groups of servers where the software release has been deployed to, and the tasks that are needed for the deployment to work smoothly. Example environments could be named Development, QA, Staging or Production. Environments have permissions that allow fine grained control of who can deploy, edit or view an environment and record the full history of releases deployed to it.
- **Release** – Identifies a snapshot of artifacts and its associated data such as commits, Jira issues and the builds that were used to test it. As a release contains the information of the difference between itself and the release beforehand, it’s very easy to see the changes between releases or to show the difference between the software deployed on two different environments. Releases also track what environments they have been deployed to.
How do deployment projects work?

Consider the following diagram:

On this page:
- What are deployment projects?

What is Continuous Delivery?
Continuous Delivery is the practice where all changes made to a software project are automatically built, tested and made ready for deployment to users. In practice, once the project has been built and tested it is ‘staged’ somewhere where it can be manually verified and then made available to users.

Unlike Continuous Deployment (the process where code changes are automatically built, tested and deployed without human intervention), typically there is a decision made by a human being to whether or not the software is of sufficient quality or if it is the correct time for the business to make the software available to its users.

Artifacts

Create and test deployable artifacts with build plans. Ensure any artifacts you wish to deploy with Bamboo are flagged as "shared" to make them available to the deployment instructions of the environment.
Releases

Any artifact that has been successfully tested can be used to create a release; you can create as many releases as you like. Bamboo will add other metadata such as related commits and Jira issues to each release which enable reporting and tracking as it moves through your environments.

Environments

Environments in Bamboo reflect the development, testing and production environments in your IT infrastructure – hostnames and authentication credentials for each environment reside at the task level inside your deployment jobs. At any point in time, you will be able to see which release is running in each environment, which release it replaced, when it was deployed and who deployed it. You will also be able to see any associated Jira issues.

Understanding deployment releases

Key to getting the most out of deployment projects is understanding what releases are, and how you should be using them.

It is also important to understand the difference and relationship between ‘artifacts’ - the results of a build plan - and ‘releases’ - a snapshot of artifacts at a specific time that can be deployed somewhere.

On this page:

- What are artifacts?
- What are deployment releases?
- Why use releases?
- How artifacts and deployment releases work together
- The next step

What are artifacts?

When the continuous integration process is triggered by a developer committing code, the first stage of the process compiles the code, runs tests and then assembles the code into binaries. These assembled binaries are known as ‘artifacts’. The build process can produce build artifacts at any stage of the build that can then be shared with other builds or deployment projects.

Since Bamboo manages artifacts, any artifacts that are needed by builds or deployments are automatically transferred by Bamboo to a remote server as needed, so long as that build or deployment project declares that it needs the artifact to complete its work.

For more information, see Sharing artifacts.

What are deployment releases?

Releases are used to track exactly what software was deployed to an environment. In essence, a release is a snapshot of any number of artifacts that will be used in the deployment process and their associated metadata, such as Jira issues, code changes and any test metadata that might be relevant to what is being deployed.

A release is created from the result of a single build. When you view a release, you can see all the code changes, Jira issues and other metadata that were used when making the artifact for that build. This information can be used for purposes such as release notes, quality control and infrastructure planning, and allows you to compare any two releases to see the changes between them.

Why use releases?

In Bamboo, releases are tracked against environments, which represent a server or group of servers that you wish to deploy your software to. Because each environment can only host a single active release at any one time, Bamboo gives a unique release name to the software being deployed. By checking the environments for our project, we can quickly identify:

- Where releases have been deployed
- Which release is currently deployed
- The release deployment history
- The release deployment status.

Another key feature of releases is that as well as providing a deployable snapshot of your artifacts, they also collate the Jira issues, commit record and test & build metadata for the specific series of changes associated with the release. This enables much smoother reporting and tracking as the release moves through your environments, and allows you to easily track changes between releases.
How artifacts and deployment releases work together

The relationship between artifacts and releases shows the ‘hand-over point’ between Bamboo builds and Bamboo deployments.

As the diagram shows, a developer who is responding to Jira issues, commits a code change and triggers a build. This build produces a number of artifacts. In a deployment, these artifacts are assembled into a release, and the Jira issue, commits and test/build metadata are added. This release then gets a unique identification name which serves as an identifier throughout the system. You can define the unique identifier according to your needs using the release naming system.

Once a release has been created, it is now ready to be deployed to an environment.

The next step

The next step is to examine and understand the deployment project workflow. Learn more about the deployment project workflow.

Deployment projects workflow

Deployment projects are an important feature of the continuous deployment philosophy. Identifying and understanding the key configuration steps for a deployment project will help you to gain a better insight into how a deployment project functions.

On this page:

- Deployment project prerequisites
- Step 1: Create a new deployment project
- Step 2: Decide on a release naming scheme
- Step 3: Decide who can view and edit the project
- Step 4: Create a deployment environment
- Step 5: Customize your deployment environment
- Step 6: Start deploying!

Deployment project prerequisites

There are a number of prerequisites that must be in place before you can start using deployment projects. The prerequisites are:

1. A build plan
2. Artifacts to deploy (these are produced by the build plan and shared)

Step 1: Create a new deployment project

Creating the deployment project is the first step. Here we will give the project a name and a description, but most importantly we associate the deployment project with an existing Bamboo build plan. This is why we must have a build plan available to associate with our new deployment project.

Learn more about creating a deployment project here.
Step 2: Decide on a release naming scheme

The next step is to configure the release naming scheme for the deployment project. The release naming scheme will define how Bamboo names the releases that you create from your build artifacts for deployment. You can use either a simple release naming scheme, or a scheme that uses global or plan variables already defined in Bamboo.

Learn more about release naming schemes here.

Step 3: Decide who can view and edit the project

You need to decide who can view and edit the deployment project: This is done using the permission scheme. You can add or remove individuals or groups from the scheme, and give them access to either view and/or edit the project.

Learn more about the permissions scheme here.

Step 4: Create a deployment environment

The next step is to create a deployment environment. A deployment environment represents the servers or groups of servers where the software has been deployed, and any tasks needed for the deployment to go smoothly. You can call the deployment environment anything you like, though typical names are QA, Staging and Production.

Learn more about creating a deployment environment here.

Step 5: Customize your deployment environment

Once you have created your deployment environment, you need to set it up to reflect the needs of your project. You can control most aspects of the deployment environment, including:

- **Tasks** - Run executable tasks during the deployment process, for example downloading a needed artifact from a different plan
- **Triggers** - Decide which events or schedule points will trigger off deployment of your project to an environment
- **Permissions** - Decide who can view and edit your deployment environment
- **Agents** - Control which agents you will use to support your deployment process
- **Notifications** - Create a notification scheme to keep you informed about your deployment progress
- **Variables** - Assign variables for your deployment projects

Step 6: Start deploying!

Once you have set up your deployment project, you’re ready to start the deployment process.

A sample deployment project

On this page we will examine a sample deployment project, and work through the steps required to get a deployment project up and running.

On this page:

- Step 1: Create a deployment project
- Step 2: Define the release naming scheme
- Step 3: Create a deployment environment
- Step 4: Add some environment tasks
- Step 5: Let’s deploy!
- Step 7: Additional deployment environment options

Step 1: Create a deployment project

The first step in creating a deployment project is to associate the project with an existing build plan. This is done at the same time as creating the deployment project. To create a new deployment project, and associate an existing build plan with it:

1. Click Create > Create deployment project in the drop down menu from the header bar. The 'Set up deployment project' screen will appear.
2. Use the Source build plan to select an existing build plan. Bamboo will identify any relevant build plans in the menu:
In this example we can see that the associated build plan is the one for project Bonsai

3. Complete the Name and Description fields as required
4. Click Create deployment project. Your deployment project will be created, and will automatically be associated with the build plan you selected above.

Step 2: Define the release naming scheme

The next step is to provide a version naming strategy for the deployment project. This will define how the deployment project will ascribe names to current and subsequent artifact bundles that it generates. See Naming versions for deployment releases for more information. To configure your version naming scheme:

1. From the deployment project configuration screen, click Release versioning to display the deployment project release versioning screen:

   2. Complete the required fields according to your naming scheme. In this example we can see that a simple naming scheme has been adopted - the next name will be 1.0, and the subsequent 1.1 etc
   3. Click Save to save your naming scheme.

Step 3: Create a deployment environment

Once we have defined our naming scheme, we need to create a deployment environment for the artifact(s) to be deployed into. Typically, deployment environments include Test, Staging, QA and Production, however there's no limit to creating useful deployment environments. Let's look at how it's done:

1. From the deployment project configuration screen, click Add environment to open the Set up environment screen:
2. Enter the name of the deployment environment, and a brief description. In this example we will call our environment Dev Sandbox, and give it a suitable description.

3. Click either Create and back or Continue to task setup to create the environment. The next stage will be to add some tasks, so clicking Continue to task setup will take us straight to the next step.

Step 4: Add some environment tasks

Tasks are activities that the deployment project will perform in order to run. These could be checking out some code from a repository, downloading an artifact from a server or running a script. Let's have a look at how to add a couple of tasks to the deployment environment:

1. If you continued to task setup from the environment creation process, then you will already be at the Set up tasks screen. Alternatively, From the deployment project configuration screen, click Set up tasks:

2. Click Add task to display the list of tasks that are available to you:

In this example, we will add a simple script task to run as part of our build. Clicking on the task we wish to add adds it to the set up
tasks screen, and allows us to configure the individual task:

3. Click **Save** to save the individual task configuration, and then on **Finish deployment project** to complete configuration of the script task for the deployment environment. In reality, we would require a number of tasks, not least one to obtain an artifact for use in the deployment. The following task configuration for a production environment includes an artifact download, DB change script, a Tomcat deployment, source code checkout and a Maven 3.x task:

---

**Step 5: Let’s deploy!**

Our sample deployment project now has all of the elements required to run. We can trigger the deployment project manually by clicking on the appropriate deploy icon on the projects page:
Step 7: Additional deployment environment options

But deployments don’t end here. This simple example is just a snapshot of how a deployment project is configured and works. Bamboo deployment projects feature a host of additional features to help you manage your development and deployment processes. These include:

- **Automated triggering** - choose to automatically deploy after a successful build plan completes, or at a scheduled time
- **Agents** - Assign specific agents, elastic agents or image configurations to execute the deployment for the environment
- **Variables** - Incorporate variables for use when deploying versions to environments
- **Permissions** - Define what users are allowed to view, edit and deploy in the environment
- **Notifications** - Define who and how notifications about events for the environment are made.

Creating and configuring a deployment project

Creating a deployment project from a plan is easy with Bamboo. A deployment is a container that holds:

- Environments that represent the physical environments, such as QA, Staging and Production
- Releases which represent the actual software artifacts being deployed - these include the issues and commits which make up the release.

To create a new deployment project you must:

1. Provide a name and a description that represents your project
2. Associate the project with a build plan. The build plan will produce the artifacts you will snapshot into a release and deploy to the environment. Associating the deployment project with a build plan tells the deployment project which set of artifacts to use for the deployment.

If you are using plan branches, you will also need to associate the deployment with the plan branch. The plan branch represent a build for a branch within the version control system that inherits the configuration defined by the parent plan. Any new branch created is automatically built and tested using the same build configuration as the parent. When the plan branch build succeeds, it can be merged back into master.

Learn more about **Deployments from branches**.

**Creating a new deployment project**

**To create a new deployment project:**

1. Click **Create > Create deployment project** in the drop down menu from the header bar. The ‘Setup deployment project’ screen will appear:
If your build plan has a plan branch, Bamboo will detect it and offer an additional field for completion:

2. Complete the 'Setup deployment project' screen using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of your deployment project</td>
<td>✗</td>
</tr>
<tr>
<td>Description</td>
<td>A brief description of your deployment project</td>
<td>✓</td>
</tr>
<tr>
<td>Source Build Plan</td>
<td>The name of the plan you wish to associate with the deployment project</td>
<td>✗</td>
</tr>
<tr>
<td></td>
<td><em>Hint:</em> This field identifies the source of your deployment artifacts</td>
<td></td>
</tr>
<tr>
<td>Default plan branch</td>
<td>The plan branch that you wish to deploy. Bamboo will auto detect available plan branches for you. Choose a plan from the drop down menu.</td>
<td>✗</td>
</tr>
</tbody>
</table>

3. Click Create deployment project. The deployment project configuration screen will display:
Your deployment project has been created with the build plan relation, name and description you specified. It is now ready for configuration.

Editing the details of an existing deployment project

Bamboo allows you to edit the details of an existing deployment project.

To edit the details of an existing deployment project:

1. From the deployment project configuration screen, click the Edit details button. The Update deployment project screen will display:

   ![](update_deployment_project.png)

   - **Deployment project details**
     - **Name**: Deployment for Z Personal Branches
     - **Description**: DKText deployment project

   - **Source plan for releases**
     - **Source build plan**: Z Personal Branches - PW test

   - **Save deployment project**
     - **Cancel**

2. Complete the 'Update deployment project' screen using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Related Build Plan</td>
<td>The name of the plan you wish to associate with the deployment project. <strong>Hint</strong>: This field identifies the source of your deployment artifacts</td>
<td>✗</td>
</tr>
<tr>
<td>Name</td>
<td>The name of your deployment project</td>
<td>✗</td>
</tr>
<tr>
<td>Description</td>
<td>A brief description of your deployment project</td>
<td>✓</td>
</tr>
<tr>
<td>Default plan branch</td>
<td>The plan branch that you wish to deploy. This option will only display if your plan has a valid branch, as described above</td>
<td>✗</td>
</tr>
</tbody>
</table>

3. Click on **Save deployment project** to save your changes.

Configuring release naming

Bamboo's release naming configuration allows you to control:
What Bamboo will call the next release the deployment project generates
• Automatic incrementing of the release number each time a new release is created
• Automatic incrementing of the release number as specified by a global variable each time a new release is created.

See Naming versions for deployment releases for more information.

Configuring deployment project permissions

Bamboo gives you control over who has permission to View and Edit aspects of your deployment project.

To configure your permission strategy:

1. Click the Permissions button on the 'Deployment project configuration' screen to display the 'Edit permissions' screen:

   ![Permissions screen](image)

2. Click the Add User or Add Group button to search for and add, users or groups
3. Check the relevant 'View' and 'Edit' permission boxes to assign your desired permission scheme
4. Click Save to save your permission scheme.

Viewing a Bamboo deployment project in the YAML format

Bamboo instance administrators can view the deployment configuration in the YAML format in Deployment project configuration:

> Actions:

 Naming versions for deployment releases

Bamboo provides a range of options that allow you to control your release naming scheme. You can specify how Bamboo handles release versioning, and control automatic incrementing between releases.

Bamboo allows you to use:

• Simple incremental numbering
• Advanced numbering based upon Bamboo variables

Bamboo also allows you to manually override automatic release settings when you create a new release.

On this page:

• Simple release versioning
• Release versioning using variables

Simple release versioning

Simple release versioning allows you to specify a starting release number, for example, 1.0, which Bamboo will automatically increment. When using simple release versioning, Bamboo will increment the final number in the release name. For example:

<table>
<thead>
<tr>
<th>Release name</th>
<th>Incremented release name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1.1</td>
<td>1.2</td>
</tr>
</tbody>
</table>
To configure simple release naming:

1. Click the **Release versioning** button on the 'Deployment project configuration' screen to display the 'Release versioning' screen:

   ![Release versioning screen](image)

   - **Next release**
     - The identification for the next release name that Bamboo will create. In simple release naming, you should use something straightforward like 1.0.
     - If you want the naming scheme for the release to be applied to branches, select 'Apply the same naming scheme to versions created from branches'.

   - **Automatically increment with each new release**
     - Check the 'Numbers' checkbox to automatically increment the release number according to the 'Next release' field, as defined above. If you leave this box unchecked, no release number incrementing will occur.

   - **Preview**
     - This field allows you to preview what the next release name will look like. To view the preview, click on the **Generate preview** button next to the 'Create release name' field.
     - **Note:** In some cases, a preview may not be available.

2. Complete the 'Release versioning' screen using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Next release</strong></td>
<td>The identification for the next release name that Bamboo will create. In simple release naming, you should use something straightforward like 1.0.</td>
<td>❌</td>
</tr>
<tr>
<td></td>
<td>If you want the naming scheme for the release to be applied to branches, select 'Apply the same naming scheme to versions created from branches'.</td>
<td>✓</td>
</tr>
<tr>
<td><strong>Automatically increment with each new release</strong></td>
<td>Check the 'Numbers' checkbox to automatically increment the release number according to the 'Next release' field, as defined above. If you leave this box unchecked, no release number incrementing will occur.</td>
<td>✓</td>
</tr>
<tr>
<td><strong>Preview</strong></td>
<td>This field allows you to preview what the next release name will look like. To view the preview, click on the <strong>Generate preview</strong> button next to the 'Create release name' field. <strong>Note:</strong> In some cases, a preview may not be available.</td>
<td>-</td>
</tr>
</tbody>
</table>

3. Click **Save** to save your changes.

**Release versioning using variables**

Release versioning using variables allows you to develop more complex naming schemes, based upon variables set up within Bamboo. You
can use global, plan and build variables in your releasing scheme.

For security reasons, you can't use password variables in version names.

**Example**

You may have a plan variable called 'planvar' with a value of 'm6'. By including this variable key within the 'Next release' field, Bamboo will automatically add the variable value to the next release name, and increment it accordingly:

<table>
<thead>
<tr>
<th>Variable key</th>
<th>Variable value</th>
<th>Next release</th>
<th>Next release version</th>
<th>Subsequent Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>planvar</td>
<td>m6</td>
<td>1.0-${bamboo.planvar}$</td>
<td>1.0-m6</td>
<td>1.1-m7</td>
</tr>
</tbody>
</table>

To configure release naming using variables:

1. Click the **Release versioning** button on the 'Deployment project configuration' screen to display the 'Release naming' screen:

2. Complete the 'Create release name' field using the following data:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>The identification for the next release name that Bamboo will create. In simple release versioning, you should use something straightforward like 1.0.</td>
<td>x</td>
</tr>
</tbody>
</table>

3. Click on the **Add variable to release name** link to display the Variables selection screen:
4. Click **Add variable** to include the variable in your release naming scheme. Click on **Close** to return to the 'Release naming' screen.

5. Complete the 'Release name' field using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
</table>
| Automatically increment with each new release | 1. Check the 'Numbers' checkbox to automatically increment the release number according to the 'Next release' field, as defined above. If you leave this box unchecked, then no release number incrementing will occur.  
2. Check the 'Variables' checkbox to automatically increment selected variable(s) when a new release is created. If matching plan variable exists, its value is incremented, otherwise matching global variable is incremented. Additionally, if a release is created from a branch while 'Apply the same naming scheme to versions create from branches' option is on, the branch variable is incremented (as long as it exists) | ✔️        |
| Preview                              | This field allows you to preview what the next release name will look like. To view the preview, click on the **Generate preview** button next to the 'Create release name' field.  
**Note:** In some cases, a preview may not be available.                                                   | -         |

6. Click **Save** to save your changes.

**Example release versioning schemes**

Bamboo also allows you to use combinations of simple and variable release naming. The following table provides examples of combined naming schemes and demonstrates how careful control of the Numbers and Variables checkboxes can be used to customize your scheme.

<table>
<thead>
<tr>
<th>Naming scheme</th>
<th>Next release field</th>
<th>Numbers checkbox</th>
<th>Variables checkbox</th>
<th>Variable value</th>
<th>Next release name</th>
<th>Subsequent release name</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>
### Naming versions for deployment releases v5.14

Bamboo provides a range of options that allow you to control your release naming scheme. You can specify how Bamboo handles release versioning, and control automatic incrementing between releases.

Bamboo allows you to use:

- Simple incremental numbering
- Advanced numbering based upon Bamboo variables

Bamboo also allows you to manually override automatic release settings when you create a new release.

#### On this page:

- Simple release versioning
- Release versioning using variables

#### Simple release versioning

Simple release versioning allows you to specify a starting release number, for example 1.0, which Bamboo will automatically increment. When using simple release versioning, Bamboo will increment the final number in the release name. For example:

<table>
<thead>
<tr>
<th>Release name</th>
<th>Incremented release name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>1.11</td>
<td>1.12</td>
</tr>
<tr>
<td>1.0.1</td>
<td>1.0.2</td>
</tr>
</tbody>
</table>

**To configure simple release naming:**

1. Click the **Release versioning** button on the 'Deployment project configuration' screen to display the 'Release versioning' screen:
2. Complete the ‘Release versioning’ screen using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create release name</td>
<td>The identification for the next release name that Bamboo will create. In simple release naming, you should use something straightforward like 1.0.</td>
<td>X</td>
</tr>
<tr>
<td>Automatically increment with each new release</td>
<td>Check the ‘Numbers’ check box to automatically increment the release number according to the ‘Next release name’ field, as defined above. If you leave this box unchecked, then no release number incrementing will occur.</td>
<td>✓</td>
</tr>
<tr>
<td>Preview</td>
<td>This field allows you to preview what the next release name will look like. To view the preview, click on the <strong>Generate preview</strong> button next to the ‘Create release name’ field. <strong>Note:</strong> In some cases a preview may not be available.</td>
<td>-</td>
</tr>
</tbody>
</table>

3. Click **Save** to save your changes.

**Release versioning using variables**

Release versioning using variables allows you to develop more complex naming schemes, based upon variables set up within Bamboo. You can use global, plan and build variables in your releasing scheme.

For security reasons, you can't use password variables in version names.

**Example**

You may have a plan variable called ‘planvar’ with a value of ‘m6’. By including this variable key within the ‘Next release name’ field, Bamboo will automatically add the variable value to the next release name, and increment it accordingly:

<table>
<thead>
<tr>
<th>Variable Key</th>
<th>Variable Value</th>
<th>Next Release Name</th>
<th>Next Release</th>
<th>Subsequent Release</th>
</tr>
</thead>
<tbody>
<tr>
<td>planvar</td>
<td>m6</td>
<td>1.0-{$(bamboo.planvar)}</td>
<td>1.0-m6</td>
<td>1.1-m7</td>
</tr>
</tbody>
</table>
To configure release naming using variables:

1. Click the **Release versioning** button on the 'Deployment project configuration' screen to display the 'Release naming' screen:

![Release versioning screenshot]

2. Complete the 'Create release name' field using the following data:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>The identification for the next release name that Bamboo will create. In simple release versioning, you should use something straightforward like 1.0.</td>
<td>![X]</td>
</tr>
</tbody>
</table>

3. Click on the **Add variable to release name** link to display the Variables selection screen:

![Variables selection screenshot]

4. Click **Add variable** to include the variable in your release naming scheme. Click on **Close** to return to the 'Release naming' screen.

5. Complete the 'Release name' field using the following fields:
Bamboo also allows you to use combinations of simple and variable release naming. The following table provides examples of combined naming schemes, and demonstrates how careful control of the Numbers and Variables checkboxes can be used to customize your scheme.

**Naming versions for deployment releases v6.0**

Bamboo provides a range of options that allow you to control your release naming scheme. You can specify how Bamboo handles release versioning, and control automatic incrementing between releases.

Bamboo allows you to use:

- Simple incremental numbering
- Advanced numbering based upon Bamboo variables

Bamboo also allows you to manually override automatic release settings when you create a new release.

**On this page:**

- Simple release versioning
- Release versioning using variables

**Simple release versioning**

Simple release versioning allows you to specify a starting release number, for example, 1.0, which Bamboo will automatically increment. When using simple release versioning, Bamboo will increment the final number in the release name. For example:

<table>
<thead>
<tr>
<th>Release name</th>
<th>Incremented release name</th>
</tr>
</thead>
</table>

- **Example release Save to save your changes.**

**Example release versioning schemes**
To configure simple release naming:

1. Click the **Release versioning** button on the 'Deployment project configuration' screen to display the 'Release versioning' screen:

2. Complete the 'Release versioning' screen using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Next release</strong></td>

</tr>
<tr>
<td></td>
<td><strong>Note:</strong> In some cases, a preview may not be available.</td>
<td></td>
</tr>
</tbody>
</table>

3. Click **Save** to save your changes.

**Release versioning using variables**

Release versioning using variables allows you to develop more complex naming schemes, based upon variables set up within Bamboo. You can use global, plan and build variables in your releasing scheme.

For security reasons, you can't use password variables in version names.

**Example**

You may have a plan variable called 'planvar' with a value of 'm6'. By including this variable key within the 'Next release' field, Bamboo will automatically add the variable value to the next release name, and increment it accordingly:

<table>
<thead>
<tr>
<th>Variable key</th>
<th>Variable value</th>
<th>Next release</th>
<th>Next release version</th>
<th>Subsequent Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>planvar</td>
<td>m6</td>
<td>1.0-{$bamboo.planvar}</td>
<td>1.0-m6</td>
<td>1.1-m7</td>
</tr>
</tbody>
</table>

To configure release naming using variables:

1. Click the **Release versioning** button on the 'Deployment project configuration' screen to display the 'Release naming' screen:

For security reasons, you can't use password variables in version names.
2. Complete the 'Create release name' field using the following data:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>The identification for the next release name that Bamboo will create. In simple release versioning, you should use something straightforward like 1.0.</td>
<td></td>
</tr>
</tbody>
</table>

3. Click on the Add variable to release name link to display the Variables selection screen:

- Incrementable Variables:
  - myvar
  - zip
  - planvar

- Build Variables:
  - planKey
  - planName
  - buildNumber
  - shortPlanKey
  - buildResultKey

4. Click Add variable to include the variable in your release naming scheme. Click on Close to return to the 'Release naming' screen.

5. Complete the 'Release name' field using the following fields:
Automatically increment with each new release

1. Check the 'Numbers' checkbox to automatically increment the release number according to the 'Next release' field, as defined above. If you leave this box unchecked, then no release number incrementing will occur.
2. Check the 'Variables' checkbox to automatically increment selected variable(s) when a new release is created. If matching plan variable exists, its value is incremented, otherwise matching global variable is incremented. Additionally, if a release is created from a branch while 'Apply the same naming scheme to versions create from branches' option is on, the branch variable is incremented (as long as it exists).

Preview

This field allows you to preview what the next release name will look like. To view the preview, click on the Generate preview button next to the 'Create release name' field.

Note: In some cases, a preview may not be available.

6. Click Save to save your changes.

Example release versioning schemes

Bamboo also allows you to use combinations of simple and variable release naming. The following table provides examples of combined naming schemes and demonstrates how careful control of the Numbers and Variables checkboxes can be used to customize your scheme.

<table>
<thead>
<tr>
<th>Naming scheme</th>
<th>Next release field</th>
<th>Numbers checkbox</th>
<th>Variables checkbox</th>
<th>Variable value</th>
<th>Next release name</th>
<th>Subsequent release name</th>
</tr>
</thead>
<tbody>
<tr>

<td>1.0</td>
<td>❌</td>
<td>❌</td>
<td>-</td>
<td>1.0</td>
<td>1.0</td>
</tr>
<tr>
<td>Naturally unique variable</td>
<td>1.0-${bamboo.build Number}$</td>
<td>❌</td>
<td>❌</td>
<td>13</td>
<td>1.0-13</td>
<td>1.0-13</td>
</tr>
<tr>
<td>Number incrementing</td>
<td>1.0</td>
<td>✓</td>
<td>❌</td>
<td>-</td>
<td>1.0</td>
<td>1.1</td>
</tr>
<tr>
<td>Number incrementing + static variable</td>
<td>1.0-${bamboo.app Name}$</td>
<td>✓</td>
<td>❌</td>
<td>${bamboo.appName}$ Plan or Global variable: Awesome</td>
<td>1.0-Awesome</td>
<td>1.1-Awesome</td>
</tr>
<tr>
<td>Variable incrementing</td>
<td>1.0-${bamboo.milestone}$</td>
<td>❌</td>
<td>✓</td>
<td>${bamboo.milestone}$ Plan or Global variable: m6</td>
<td>1.0-m6</td>
<td>1.0-m7</td>
</tr>
<tr>
<td>Number and variable incrementing</td>
<td>1.0-${bamboo.app pNumber}$</td>
<td>✓</td>
<td>✓</td>
<td>${bamboo.appNumber}$ User defined variable: 1567</td>
<td>1.0-b1567</td>
<td>1.1-b1568</td>
</tr>
</tbody>
</table>

Six. Naming versions for deployment releases v6.2

Bamboo provides a range of options that allow you to control your release naming scheme. You can specify how Bamboo handles release versioning, and control automatic incrementing between releases.

Bamboo allows you to use:

- Simple incremental numbering
- Advanced numbering based upon Bamboo variables

Bamboo also allows you to manually override automatic release settings when you create a new release.

On this page:

- Simple release versioning
- Release versioning using variables
Simple release versioning

Simple release versioning allows you to specify a starting release number, for example, 1.0, which Bamboo will automatically increment. When using simple release versioning, Bamboo will increment the final number in the release name. For example:

<table>
<thead>
<tr>
<th>Release name</th>
<th>Incremented release name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>1.11</td>
<td>1.12</td>
</tr>
<tr>
<td>1.0.1</td>
<td>1.0.2</td>
</tr>
</tbody>
</table>

To configure simple release naming:

1. Click the **Release versioning** button on the 'Deployment project configuration' screen to display the 'Release versioning' screen:

![Release versioning screenshot]

2. Complete the 'Release versioning' screen using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Next release</strong></td>
<td>The identification for the next release name that Bamboo will create. In simple release naming, you should use something straightforward like 1.0.</td>
<td>✗</td>
</tr>
<tr>
<td></td>
<td>If you want the naming scheme for the release to be applied to branches, select 'Apply the same naming scheme to versions created from branches'.</td>
<td>✓</td>
</tr>
<tr>
<td><strong>Automatically increment with each new release</strong></td>
<td>Check the 'Numbers' checkbox to automatically increment the release number according to the 'Next release' field, as defined above. If you leave this box unchecked, no release number incrementing will occur.</td>
<td>✓</td>
</tr>
</tbody>
</table>
3. Click **Save** to save your changes.

**Release versioning using variables**

Release versioning using variables allows you to develop more complex naming schemes, based upon variables set up within Bamboo. You can use global, plan and build variables in your releasing scheme.

For security reasons, you can't use password variables in version names.

**Example**

You may have a plan variable called 'planvar' with a value of 'm6'. By including this variable key within the 'Next release' field, Bamboo will automatically add the variable value to the next release name, and increment it accordingly:

<table>
<thead>
<tr>
<th>Variable key</th>
<th>Variable value</th>
<th>Next release</th>
<th>Next release version</th>
<th>Subsequent Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>planvar</td>
<td>m6</td>
<td>1.0-${bamboo.planvar}</td>
<td>1.0-m6</td>
<td>1.1-m7</td>
</tr>
</tbody>
</table>

To configure release naming using variables:

1. Click the **Release versioning** button on the 'Deployment project configuration' screen to display the 'Release naming' screen:

2. Complete the 'Create release name' field using the following data:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>The identification for the next release name that Bamboo will create. In simple release versioning, you should use something straightforward like 1.0.</td>
<td>X</td>
</tr>
</tbody>
</table>

3. Click on the **Add variable to release name** link to display the Variables selection screen:
4. Click **Add variable** to include the variable in your release naming scheme. Click on **Close** to return to the ‘Release naming’ screen.

5. Complete the ‘Release name’ field using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
</table>
| **Automatically increment with each new release** | 1. Check the ‘Numbers’ checkbox to automatically increment the release number according to the ‘Next release’ field, as defined above. If you leave this box unchecked, then no release number incrementing will occur.  
2. Check the ‘Variables’ checkbox to automatically increment selected variable(s) when a new release is created. If matching plan variable exists, its value is incremented, otherwise matching global variable is incremented. Additionally, if a release is created from a branch while ‘Apply the same naming scheme to versions create from branches’ option is on, the branch variable is incremented (as long as it exists) | ✔️ |

**Preview**

This field allows you to preview what the next release name will look like. To view the preview, click on the **Generate preview** button next to the ‘Create release name’ field.

**Note:** In some cases, a preview may not be available.

6. Click **Save** to save your changes.

### Example release versioning schemes

Bamboo also allows you to use combinations of simple and variable release naming. The following table provides examples of combined naming schemes and demonstrates how careful control of the Numbers and Variables checkboxes can be used to customize your scheme.

<table>
<thead>
<tr>
<th>Naming scheme</th>
<th>Next release name</th>
<th>Numbers checkbox</th>
<th>Variables checkbox</th>
<th>Variable value</th>
<th>Next release name</th>
<th>Subsequent release name</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Static naming</strong></td>
<td>1.0</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>1.0</td>
<td>1.0</td>
</tr>
<tr>
<td><strong>Naturally unique variable</strong></td>
<td>1.0-${\text{bamboo.build Number}}$</td>
<td>-</td>
<td>-</td>
<td>13</td>
<td>1.0-13</td>
<td>1.0-13</td>
</tr>
<tr>
<td><strong>Number incrementing</strong></td>
<td>1.0</td>
<td>✔️</td>
<td>-</td>
<td>-</td>
<td>1.0</td>
<td>1.1</td>
</tr>
</tbody>
</table>
Naming versions for deployment releases v6.3

Bamboo provides a range of options that allow you to control your release naming scheme. You can specify how Bamboo handles release versioning, and control automatic incrementing between releases.

Bamboo allows you to use:

- Simple incremental numbering
- Advanced numbering based upon Bamboo variables

Bamboo also allows you to manually override automatic release settings when you create a new release.

On this page:

- Simple release versioning
- Release versioning using variables

Simple release versioning

Simple release versioning allows you to specify a starting release number, for example, 1.0, which Bamboo will automatically increment. When using simple release versioning, Bamboo will increment the final number in the release name. For example:

<table>
<thead>
<tr>
<th>Release name</th>
<th>Incremented release name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>1.11</td>
<td>1.12</td>
</tr>
<tr>
<td>1.0.1</td>
<td>1.0.2</td>
</tr>
</tbody>
</table>

To configure simple release naming:

1. Click the Release versioning button on the 'Deployment project configuration' screen to display the 'Release versioning' screen:
2. Complete the 'Release versioning' screen using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Next release</td>
<td>The identification for the next release name that Bamboo will create. In simple release naming, you should use something straightforward like 1.0. If you want the naming scheme for the release to be applied to branches, select 'Apply the same naming scheme to versions create from branches'.</td>
<td>❌</td>
</tr>
<tr>
<td>Automatically increment with each new release</td>
<td>Check the 'Numbers' checkbox to automatically increment the release number according to the 'Next release' field, as defined above. If you leave this box unchecked, no release number incrementing will occur.</td>
<td>✓</td>
</tr>
<tr>
<td>Preview</td>
<td>This field allows you to preview what the next release name will look like. To view the preview, click on the Generate preview button next to the 'Create release name' field. Note: In some cases, a preview may not be available.</td>
<td>-</td>
</tr>
</tbody>
</table>

3. Click Save to save your changes.

**Release versioning using variables**

Release versioning using variables allows you to develop more complex naming schemes, based upon variables set up within Bamboo. You can use global, plan and build variables in your releasing scheme.

For security reasons, you can't use password variables in version names.

**Example**
You may have a plan variable called 'planvar' with a value of 'm6'. By including this variable key within the 'Next release' field, Bamboo will automatically add the variable value to the next release name, and increment it accordingly:

<table>
<thead>
<tr>
<th>Variable key</th>
<th>Variable value</th>
<th>Next release</th>
<th>Next release version</th>
<th>Subsequent Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>planvar</td>
<td>m6</td>
<td>1.0-${bamboo.planvar}</td>
<td>1.0-m6</td>
<td>1.1-m7</td>
</tr>
</tbody>
</table>

To configure release naming using variables:

1. Click the **Release versioning** button on the 'Deployment project configuration' screen to display the 'Release naming' screen:

![Release versioning: Deployment for Project Bonsai](image)

2. Complete the 'Create release name' field using the following data:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>The identification for the next release name that Bamboo will create. In simple release versioning, you should use something straightforward like 1.0.</td>
<td>✗</td>
</tr>
</tbody>
</table>

3. Click on the **Add variable to release name** link to display the Variables selection screen:
Click to include the variable in your release naming scheme. Click on Close to return to the 'Release naming' screen.

Complete the 'Release name' field using the following fields:

**Automatically increment with each new release**
- Check the 'Numbers' checkbox to automatically increment the release number according to the 'Next release' field, as defined above. If you leave this box unchecked, then no release number incrementing will occur.
- Check the 'Variables' checkbox to automatically increment selected variable(s) when a new release is created. If matching plan variable exists, its value is incremented, otherwise matching global variable is incremented. Additionally, if a release is created from a branch while 'Apply the same naming scheme to versions create from branches' option is on, the branch variable is incremented (as long as it exists).

**Preview**
This field allows you to preview what the next release name will look like. To view the preview, click on the Generate preview button next to the 'Create release name' field.

**Note:** In some cases, a preview may not be available.

Click Save to save your changes.

**Example release versioning schemes**

Bamboo also allows you to use combinations of simple and variable release naming. The following table provides examples of combined naming schemes and demonstrates how careful control of the Numbers and Variables checkboxes can be used to customize your scheme.
Creating a deployment environment

Once you have created and configured your new deployment project, you can create environments for it to deploy to. Bamboo allows you to create multiple deployment environments and also allows you to manage:

- Environment details such as name and description
- Tasks
- Triggers
- Permissions
- Agents
- Notifications
- Variables

To create a new deployment environment you will need to:

1. Provide a name that represents your environment e.g. Test or Production
2. Provide a description that describes the function of your environment.

On this page:

- Creating a new deployment environment
- Using the deployment environment panel
- Editing the environment details

Related pages:

- Tasks for deployment environments
- Triggers for deployment environments
- Agents for deployment environments
- Notifications for deployment environments
- Variables for deployment environments
- Permissions for deployment environments
- Requirements for deployment environments

Deployment environments are added from the Deployment project configuration screen:

Creating a new deployment environment

To create a new deployment environment:

1. Click the blue Add environment button from the 'Deployment project configuration' screen. The 'Set up environment' screen will display:
2. Complete the 'Set up deployment project' screen using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment name</td>
<td>The name of the environment</td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td>A brief description of your deployment project</td>
<td></td>
</tr>
</tbody>
</table>

Click on **Create and back** to create the environment and return to the 'Deployment project configuration' screen.

**Note:** Because no tasks have been defined for this environment, it will appear with a red exclamation mark:

Alternatively, click on **Continue to task setup** to continue to task setup for your new environment:
See Tasks for deployment environments for more information on task configuration.

Using the deployment environment panel

All deployment environments are managed from the Deployment project configuration screen. By default, when the screen loads, each environment panel is displayed in its collapsed state. Click Edit to expand the deployment environment panel:

When expanded, the environment panel shows three separate sub-panels:

The three sub-panels provide the following functionality:

<table>
<thead>
<tr>
<th>Sub-panel</th>
<th>Functionality</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment</td>
<td>• Deploy</td>
<td>• Manually deploys to the environment</td>
</tr>
<tr>
<td></td>
<td>• Actions</td>
<td>• Allows the user to View, Delete or Move down the environment</td>
</tr>
<tr>
<td></td>
<td>• Minimize</td>
<td>• Minimize the environment panel back to its collapsed state</td>
</tr>
<tr>
<td>How you want to deploy</td>
<td>• Edit tasks</td>
<td>• Allows the user to edit the tasks associated with the environment</td>
</tr>
<tr>
<td>Other settings</td>
<td>• Triggers</td>
<td>A set of optional settings that make your Bamboo deployments run more smoothly</td>
</tr>
<tr>
<td></td>
<td>• Environment permissions</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Agents assignment</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Notifications</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Variables</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Environment permissions</td>
<td></td>
</tr>
</tbody>
</table>

Editing the environment details

Bamboo allows you to change both the environment name and the description. To edit these details:

1. Expand the environment panel and click the pencil icon next to the environment name. The 'Update environment' screen will display:

2. Complete the 'Update deployment project' screen using the following fields:
3. Click **Save environment** to save your changes.

### Tasks for deployment environments

Once you have created and configured your new deployment project and deployment environments, you can set up associated tasks for the deployment process. Bamboo allows you to execute a range of different tasks upon deployment including:

- Bash and other shell commands
- Bespoke written scripts
- SCP, SSH and Artifact handler tasks
- Ant executables
- Maven 1.x, 2.x & 3.x executables
- Tomcat executables
- Heroku deployments

**On this page:**

- Add an environment task
- Some useful deployment tasks
  - Deploying with Tomcat
  - Copying and moving files with SCP
  - Integrating with Heroku
  - Deploying ASP.NET applications with MSDeploy
- Assign a final task

---

### Add an environment task

You can add tasks to a deployment environment either while you create the environment or afterwards. You can modify tasks any time after creating them.

1. Open your deployment project and expand the relevant environment panel.
2. Click **Edit tasks** (under 'How you want to deploy').
   The 'Clean working directory' and 'Artifact download' tasks are included by default:

   ![Deployment tasks](image)

   - [Clean working directory task](#)
   - [Artifact download](#)
   - [Download release contents](#)
   - [Final tasks](#)

   **Set up tasks: Dev Sandbox 2**

   - Select a task from the list on the left to configure it.

3. Click **Add task** and choose a task. Only tasks applicable to the deployment environment will be available for selection.
4. Configure the task according to the needs of your deployment project. Different tasks will have different requirements.

   Remember that capability and requirement matching is still in effect for deployment environments. If your task does not have the right capabilities it will not be executed, even if the relationship has been defined.

5. Click **Save** when you have finished.
6. Click **Back to deployment project** to return to the deployment project page.

**Some useful deployment tasks**

**Deploying with Tomcat**

You can use Bamboo to deploy and manage your Java web application with Tomcat 6 or 7, without having to directly interact with Maven, Ant or write special scripts.

See [Using Tomcat with Bamboo for continuous deployment](#).

**Copying and moving files with SCP**

You can use the Bamboo SCP task to upload files from Bamboo directly to a remote server as part of a Bamboo job. The SCP task is able to copy multiple files and preserves the directory structure for the copied files.

See [Using the SCP task in Bamboo](#).

**Integrating with Heroku**

You can use Bamboo to deploy your Java web application to the [Heroku cloud platform](#).

See [Using the Heroku task in Bamboo](#).

**Deploying ASP.NET applications with MSDeploy**

You can use Bamboo to deploy your ASP.NET web application by using a **Script** task to run `msdeploy.exe`. The MSDeploy command-line syntax is available at: [http://technet.microsoft.com/en-us/library/dd569106(v=ws.10).aspx](http://technet.microsoft.com/en-us/library/dd569106(v=ws.10).aspx)

**Assign a final task**

Once all of your tasks have been configured, you may assign some or all of them to be Final Tasks. Final Tasks are always executed at the end of the build.

1. Open your deployment project and expand the relevant environment panel.
2. Click **Edit tasks** (under ‘How you want to deploy’).
3. To make a task final, simply drag the task below the ‘Final tasks’ bar:
Triggers for deployment environments

Use deployment triggers for automatic management of how and when Bamboo starts deployment projects.

Deployments can be triggered automatically based on:

- a successful build of a plan branch
- a successful deployment to some other environment
- a successful build of a plan stage
- a schedule (specific time and date, at an interval, or Crone-based)

**Note:** You can also start deployments manually.

When an automatic deployment starts, Bamboo creates a new release based on the latest successful build of the plan branch that is defined in the deployment trigger. If there is only one branch in the plan, it is selected by default.

### On this page:

- Configuring Bamboo deployment triggers
  - Common parameters
  - Trigger-specific parameters
    - After successful build plan
    - After successful deployment
    - After successful stage
    - Scheduled
  - How to find deployment triggers configuration in Bamboo

### Configuring Bamboo deployment triggers

You can customize the deployment by specifying the details of each trigger. Triggers configuration lives in the environment settings of a deployment project.

If you don’t know where to find the trigger configuration in Bamboo, see How to find deployment triggers configuration in Bamboo.

#### Common parameters

The list of parameters that are the same for all deployment triggers.

**Trigger description** (Optional)

A meaningful name of a trigger by which you can identify the trigger in the GUI.

**Disable this trigger** (Optional)

Select the check box to ignore the trigger in deployments.

#### Trigger-specific parameters

The list of parameters that are specific for each deployment trigger type.

**After successful build plan**
The trigger starts a deployment after a successful build of the specified plan branch. If there is only one existing plan branch, it is selected by default and the branch selection options are hidden.

**Branch to trigger this deployment** *(Required)*  
Specifies the branch that must be successfully built before the deployment.

You can specify the following:

- **use main plan branch**: displays the name of the plan branch set as the main plan branch
- **use a custom plan branch**: displays a selection list that is pre-filled with all branches in the deployment project

**After successful deployment**  
Starts a deployment after a successful deployment on another environment.

**Triggering environment** *(Required)*  
Specifies the environment on which a successful deployment must be performed to start the new deployment.

**After successful stage**  
Starts a deployment after a successful build of the specified stage of a plan. If there is only one existing stage, it is selected by default.

**Plan stage to trigger this deployment** *(Required)*  
Specifies the stage on which a successful deployment must be performed to start the new deployment.

**Scheduled**  
Starts a deployment according to a customized schedule with artifacts from a specific branch.

**Schedule** *(Required)*  
Click the pencil icon to open the schedule editor. You can select from:

- Daily
- Days per week
- Days per month
- Cron expression

and provide the further details in the fields displayed following to the selection.

**Branch to provide artifacts for this deployment** *(Required)*  
Specifies the branch from which Bamboo provides artifacts for the deployment.

You can specify the following:

- **use main plan branch**: displays the name of the plan branch set as the main plan branch
- **use a custom plan branch**: displays a selection list that is pre-filled with all branches in the deployment project

**How to find deployment triggers configuration in Bamboo**  
Deployment triggers are set as part of the of the environment configuration for a deployment project.

To get to the environment configuration details view:

1. Click **Deploy** in the top main Bamboo menu and select All deployment projects.
2. Click the name of an environment to display the environment details view.
3. Click the ellipsis (...) in the upper right corner of the view and select **Edit environment**:

![Edit environment](image)

4. Once you are in the environment edit view, a list of all existing environments is displayed with expanded information about the environment that you want to edit.

   If you want to edit an environment that is different from the expanded one, you can click **Edit** next to the name of the environment:
5. In the **Other environment settings** section, click **Triggers**:

6. In the **Edit triggers** you can add, remove, or configure triggers.

### Triggers for deployment environments v5.14

Use deployment triggers for automatic management of how and when Bamboo starts deployment projects.

Deployments can be triggered automatically based on:

- a successful build of a plan branch
- a successful deployment to some other environment
- a successful build of a plan stage
- a schedule (specific time and date, at an interval, or Crone-based)

**Note:** You can also start deployments manually.

When an automatic deployment starts, Bamboo creates a new release based on the latest successful build of the plan branch that is defined in the deployment trigger. If there is only one branch in the plan, it is selected by default.

## Configuring Bamboo deployment triggers

You can customize the deployment by specifying the details of each trigger. Triggers configuration lives in the environment settings of a deployment project.

If you don’t know where to find the trigger configuration in Bamboo, see How to find deployment triggers configuration in Bamboo.

### Common parameters

The list of parameters that are the same for all deployment triggers.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trigger description</td>
<td>no</td>
<td>A meaningful name of a trigger by which you can identify the trigger in the GUI.</td>
</tr>
<tr>
<td>Disable this trigger</td>
<td>no</td>
<td>Select the check box to ignore the trigger in deployments.</td>
</tr>
</tbody>
</table>

**Trigger-specific parameters**

The list of parameters that are specific for each deployment trigger type.

### After successful build plan

The trigger starts a deployment after a successful build of the specified plan branch. If there is only one existing plan branch, it is selected by default and the branch selection options are hidden.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Branch to trigger this deployment</td>
<td>yes</td>
<td>Specifies the branch that must be successfully built before the deployment. You can specify the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• use main plan branch: displays the name of the plan branch set as the main plan branch</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• use a custom plan branch: displays a selection list that is pre-filled with all branches in the deployment project</td>
</tr>
</tbody>
</table>

### After successful deployment

Starts a deployment after a successful deployment on another environment.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Triggering environment</td>
<td>yes</td>
<td>Specifies the environment on which a successful deployment must be performed to start the new deployment.</td>
</tr>
</tbody>
</table>

### After successful stage

Starts a deployment after a successful build of the specified stage of a plan. If there is only one existing stage, it is selected by default.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plan stage to trigger this deployment</td>
<td>yes</td>
<td>Specifies the stage on which a successful deployment must be performed to start the new deployment.</td>
</tr>
</tbody>
</table>

### Scheduled

Starts a deployment according to a customized schedule with artifacts from a specific branch.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schedule</td>
<td>yes</td>

</tbody>
</table>
### Branch to provide artifacts for this deployment

<table>
<thead>
<tr>
<th>yes</th>
</tr>
</thead>
</table>

Specifies the branch from which Bamboo provides artifacts for the deployment.

You can specify the following:

- **use main plan branch**: displays the name of the plan branch set as the main plan branch
- **use a custom plan branch**: displays a selection list that is pre-filled with all branches in the deployment project

---

### How to find deployment triggers configuration in Bamboo

Deployment triggers are set as part of the of the environment configuration for a deployment project.

To get to the environment configuration details view:

1. Click **Deploy** in the top main Bamboo menu and select **All deployment projects**.
2. Click the name of an environment to display the environment details view.
3. Click the ellipsis (…) in the upper right corner of the view and select **Edit environment**:

![Edit environment button](image)

4. Once you are in the environment edit view, a list of all existing environments is displayed with expanded information about the environment that you want to edit.

   If you want to edit an environment that is different from the expanded one, you can click **Edit** next to the name of the environment:

![Edit button](image)

5. In the **Other environment settings** section, click **Triggers**:

![Triggers section](image)

6. In the **Edit triggers** you can add, remove, or configure triggers.

---

### Triggers for deployment environments v6.1

Use deployment triggers for automatic management of how and when Bamboo starts deployment projects.

Deploymnts can be triggered automatically based on:

- a successful build of a plan branch
- a successful deployment to some other environment
- a successful build of a plan stage
• a schedule (specific time and date, at an interval, or Crone-based)

Note: You can also start deployments manually.

When an automatic deployment starts, Bamboo creates a new release based on the latest successful build of the plan branch that is defined in the deployment trigger. If there is only one branch in the plan, it is selected by default.

On this page:
• Configuring Bamboo deployment triggers
  • Common parameters
  • Trigger-specific parameters
    • After successful build plan
    • After successful deployment
    • After successful stage
    • Scheduled
  • How to find deployment triggers configuration in Bamboo

Configuring Bamboo deployment triggers

You can customize the deployment by specifying the details of each trigger. Triggers configuration lives in the environment settings of a deployment project.

If you don't know where to find the trigger configuration in Bamboo, see How to find deployment triggers configuration in Bamboo.

Common parameters

The list of parameters that are the same for all deployment triggers.

Trigger description (Optional)

A meaningful name of a trigger by which you can identify the trigger in the GUI.

Disable this trigger (Optional)

Select the check box to ignore the trigger in deployments.

Trigger-specific parameters

The list of parameters that are specific for each deployment trigger type.

After successful build plan

The trigger starts a deployment after a successful build of the specified plan branch. If there is only one existing plan branch, it is selected by default and the branch selection options are hidden.

Branch to trigger this deployment (Required)

Specifies the branch that must be successfully built before the deployment.

You can specify the following:
• use main plan branch: displays the name of the plan branch set as the main plan branch
• use a custom plan branch: displays a selection list that is pre-filled with all branches in the deployment project

After successful deployment

Starts a deployment after a successful deployment on another environment.

Triggering environment (Required)

Specifies the environment on which a successful deployment must be performed to start the new deployment.

After successful stage

Starts a deployment after a successful build of the specified stage of a plan. If there is only one existing stage, it is selected by default.

Plan stage to trigger this deployment (Required)

Specifies the stage on which a successful deployment must be performed to start the new deployment.

Scheduled

Starts a deployment according to a customized schedule with artifacts from a specific branch.

Schedule (Required)

Click the pencil icon to open the schedule editor. You can select from:

• Daily
• Days per week
• Days per month
• Cron expression

and provide the further details in the fields displayed following to the selection.
Branch to provide artifacts for this deployment (Required)

Specifies the branch from which Bamboo provides artifacts for the deployment.

You can specify the following:

- use main plan branch: displays the name of the plan branch set as the main plan branch
- use a custom plan branch: displays a selection list that is pre-filled with all branches in the deployment project

How to find deployment triggers configuration in Bamboo

Deployment triggers are set as part of the the environment configuration for a deployment project.

To get to the environment configuration details view:

1. Click Deploy in the top main Bamboo menu and select All deployment projects.
2. Click the name of an environment to display the environment details view.
3. Click the ellipsis (…) in the upper right corner of the view and select Edit environment:

4. Once you are in the environment edit view, a list of all existing environments is displayed with expanded information about the environment that you want to edit.

If you want to edit an environment that is different from the expanded one, you can click Edit next to the name of the environment:

5. In the Other environment settings section, click Triggers:

6. In the Edit triggers you can add, remove, or configure triggers.

Agents for deployment environments

Bamboo offers a range of optional settings to make your deployment project function more smoothly. Bamboo allows you to assign specific agents, elastic agents or image configurations to execute the deployment for the environment.

Important Note
Assigning agents to deployment tasks may reduce your build capacity. When an agent is assigned, no other builds or deployments can run on it unless they are also explicitly assigned to use that agent or image configuration.
Configuring deployment agents

Deployment environment agents are configured as part of the Other settings section of the environment panel.

To configure your deployment agent:

1. Open your deployment project and expand the relevant environment panel. In the Other settings section, click on the Agents button. The ‘Assigned agents’ screen will display:

   ![Agent Configuration Screen]

2. Enter an agent name, or use the drop down menu to select an appropriate agent:

   ![Agent Selection Screen]

   Only agents applicable to the deployment environment will be available for selection.

   Remember that capability and requirement matching still applies for deployment environments. If your agent does not have the right capabilities it will not be assigned at runtime even if the relationship has been defined.

3. Click on Save to save your agent scheme

4. You can remove an unwanted agent by clicking the associated cross on the right hand side of the screen.

Notifications for deployment environments

Bamboo offers a range of optional settings to make your deployment project function more smoothly. Notifications allow you to assign a specific notification scheme to events triggered by the deployment environment. Notification events include start and finish of a deployment, and may be delivered by any of:

- User or group notification
- Email
- Hipchat
- Instant Messaging

To set up a notification you will need to:

1. Select a triggering event
2. Configure a mechanism for delivering notifications
Configuring deployment notifications

Deployment environment notifications are configured as part of the Other settings section of the environment panel.

To configure your deployment notifications:

1. Open your deployment project and expand the relevant environment panel. In the Other settings section, click on the Notifications button. The 'Edit notifications' screen will display:

```
Edit environment notifications: Dev Sandbox

Define who receives notifications about deployment events for this environment.

- There is currently no instant messaging server configured for Bamboo. Instant message notifications will not be sent.

Add an instant messaging server now.

Add notification

There are currently no notifications set up for this plan.

Back to deployment project
```

2. Click the Add notification button. The 'Add a new notification' window will display:

```
Add a new notification

Add notification

Event
- Deployment Started and Finished

Notifications sent when a deployment is started or finished.

Recipient type
- User

User
- Start typing to select

User to receive notification

Add Cancel
```

3. Complete the 'Edit notifications' screen by selecting the event to trigger the notification:

**Deployment started and finished**
Notification is issued when a deployment is started and finished

**Deployment finished**
Notification is issued only when deployment is finished

And configuring the notification delivery system:

<table>
<thead>
<tr>
<th>Recipient Type</th>
<th>Data requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>User</td>
<td>Username of the user</td>
</tr>
<tr>
<td>Hipchat</td>
<td>Hipchat API token, Hipchat room name, Room participants notification</td>
</tr>
<tr>
<td>Group</td>
<td>Groupname</td>
</tr>
</tbody>
</table>
Email Address | Email address
---|---
IM Address | Instant messaging address

**Note:** If you have not done so, you may need to set up an IM server for IM notifications to work correctly.

4. **Click the Add button to add your notification**
5. **You can edit or remove notifications by clicking on the associated Edit or Remove link on the right hand side of the screen.**

### Notifications for deployment environments v5.14

Bamboo offers a range of optional settings to make your deployment project function more smoothly. Notifications allow you to assign a specific notification scheme to events triggered by the deployment environment. Notification events include start and finish of a deployment, and may be delivered by any of:

- User or group notification
- Email
- Hipchat
- Instant Messaging

To set up a notification you will need to:

1. Select a triggering event
2. Configure a mechanism for delivering notifications

**On this page:**

- Configuring deployment notifications

**Configuring deployment notifications**

Deployment environment notifications are configured as part of the Other settings section of the environment panel.

**To configure your deployment notifications:**

1. **Open your deployment project and expand the relevant environment panel. In the Other settings section, click on the Notifications button.** The 'Edit notifications' screen will display:

   ![Edit environment notifications: Dev Sandbox](image)

Variables for deployment environments

**Deployment variables**

Bamboo manages a number of standard reserved variables that are available when deploying a project.

Variables later in the following list override the previous ones in case of repeating names:

- global variables
- release variables as defined below
- user variables defined at environment level
- the autogenerated variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.agentId</td>
<td>The id of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td>bamboo.agentWorkingDirectory</td>
<td>The path to the working directory on the agent. This is not the same as the Bamboo working directory.</td>
</tr>
<tr>
<td>bamboo.build.working.directory</td>
<td>The path to the working directory for Bamboo. This is used by both the build plan and the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.environment</td>
<td>The name of the environment that the release is to be deployed to.</td>
</tr>
<tr>
<td>bamboo.deploy.project</td>
<td>The name of the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.rollback</td>
<td>True if the release being deployed is older than the release being replaced.</td>
</tr>
<tr>
<td>bamboo.deploy.release</td>
<td>The name of the release that is being deployed. Either .release or .version can be used - both return the name of the release being deployed.</td>
</tr>
<tr>
<td>bamboo.deploy.version</td>
<td></td>
</tr>
</tbody>
</table>

For Bamboo variables to do with build plans, and releases, see Bamboo variables.

**Configuring variables for deployment environments**

Deployment environment variables are configured as part of the Other settings section of the environment panel.

**On this page:**
- Deployment variables
- Configuring variables for deployment environments

**Related pages:**
- Bamboo variables
- Defining global variables
- Defining plan variables
- Running a plan build manually

To configure an environment variable:

1. Open your deployment project and expand the relevant environment panel. In the Other settings section, click **Variables**:
2. Enter a valid key and value into the relevant fields in the Variables screen.
3. Click on Add to add the variable scheme.

   **Edit variables: bdog.atlassian.net**

   Define variables to be used by your deployment tasks. You can use any of the keys below in your task configuration or scripts and it will be automatically substituted with the value. You can override global variables by using the same key.

   For task configuration fields, use the syntax `$(bamboo.myvariablename)`. For inline scripts, variables are exposed as shell environment variables which can be accessed using the syntax `$BAMBOO_MY_VARIABLE_NAME` (Linux/Mac OS X) or `%BAMBOO_MY_VARIABLE_NAME%` (Windows).

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Choose from global variables or type in your own</td>
<td>Add</td>
</tr>
</tbody>
</table>

4. You can remove unwanted variables by clicking the relevant cross icon on the right of the Variables screen.
5. Click **Back to deployment project** to return.

**Permissions for deployment environments**

Bamboo offers a range of optional settings to make your deployment project function more smoothly. Deployment environment permissions allow you to configure which groups or individuals can view, edit or deploy a project.

Note that the global Bamboo permissions still take precedence. Where a user has environment permissions enabled but project permissions disabled, they will still be unable to access a deployment environment. Please see Bamboo permissions and Creating and configuring a deployment project for more information on managing deployment project permissions.

**On this page:**
- Configuring deployment environment permissions

**Configuring deployment environment permissions**

Deployment environment permissions are configured as part of the Other settings section of the environment panel.

To configure your permission strategy:

1. Open your deployment project and expand the relevant environment panel. In the Other settings section, click on the **Permissions** button.
utton. The ‘Edit permissions’ screen will display:

![Edit environment permission](image)

1. Click the **Add User** or **Add Group** button to search for and add, users or groups.
2. Check the relevant ‘View’, ‘Edit’ or ‘Deploy’ permission boxes to assign your desired permission scheme.
3. Click **Save** to save your permission scheme.

### Requirements for deployment environments

Specify requirements for deployment environments to route the deployment plan execution to agents with matching capabilities. This way, agents that aren’t executing dedicated deployments will be available for other jobs.

To view and manage requirements for deployment environments:

1. Click **Deploy** in the top main Bamboo menu and select **All deployment projects**.
2. Click the name of an environment to display the environment details view.
3. Click the ellipsis (…) in the upper right corner of the view and select **Edit environment**:

   ![Edit environment](image)

4. Once you are in the environment edit view, a list of all existing environments is displayed with expanded information about the environment that you want to edit.

   If you want to edit an environment that is different from the expanded one, you can click **Edit** next to the name of the environment.

5. To manage and view existing requirements, click **Agents assignment**:

   ![Agents assignment](image)

   In the **Agents assignment** view you can:
   
   - add and remove capabilities required from an agent to deploy an environment
   - check which agents and/or elastic images meet the requirements of your deployment environment
   - view capabilities that are required based on the requirements of the deployment tasks specified for the environment
Specify requirements for deployment environments to route the deployment plan execution to agents with matching capabilities. This way, agents that aren’t executing dedicated deployments will be available for other jobs.

To view and manage requirements for deployment environments:

1. Click **Deploy** in the top main Bamboo menu and select **All deployment projects**.
2. Click the name of an environment to display the environment details view.
3. Click the ellipsis (…) in the upper right corner of the view and select **Edit environment**.

4. Once you are in the environment edit view, a list of all existing environments is displayed with expanded information about the environment that you want to edit.

If you want to edit an environment that is different from the expanded one, you can click **Edit** next to the name of the environment.

5. To manage and view existing requirements, click **Agents assignment**:

In the **Agents assignment** view you can:

- add and remove capabilities required from an agent to deploy an environment
- check which agents and/or elastic images meet the requirements of your deployment environment
- view capabilities that are required based on the requirements of the deployment tasks specified for the environment
Requirements for deployment environments v6.0

Specify requirements for deployment environments to route the deployment plan execution to agents with matching capabilities. This way, agents that aren’t executing dedicated deployments will be available for other jobs.

To view and manage requirements for deployment environments:

1. Click **Deploy** in the top main Bamboo menu and select **All deployment projects**.
2. Click the name of an environment to display the environment details view.
3. Click the ellipsis (…) in the upper right corner of the view and select **Edit environment**:

   ![Edit environment button]

4. Once you are in the environment edit view, a list of all existing environments is displayed with expanded information about the environment that you want to edit.

   If you want to edit an environment that is different from the expanded one, you can click **Edit** next to the name of the environment.

5. To manage and view existing requirements, click **Agents assignment**:

   ![Agents assignment view]

   In the **Agents assignment** view you can:
   - add and remove capabilities required from an agent to deploy an environment
   - check which agents and/or elastic images meet the requirements of your deployment environment
view capabilities that are required based on the requirements of the deployment tasks specified for the environment

Agents assignment: QA

This environment can only be deployed by agents whose capabilities meet the 2 requirements below.

Can be deployed by 1 agent (none online)
3 elastic images

<table>
<thead>
<tr>
<th>Required capability</th>
<th>Required by task</th>
<th>Agents</th>
<th>Images</th>
</tr>
</thead>
<tbody>
<tr>
<td>JDK 1.8</td>
<td>exists</td>
<td>Maven 3</td>
<td>1</td>
</tr>
<tr>
<td>Maven 3</td>
<td>exists</td>
<td>Maven 3</td>
<td>1</td>
</tr>
</tbody>
</table>

Dedicated agents and images

You can dedicate specific agents or images to execute all deployments for this environment. For more information, see Agents for deployment environments.

Creating a deployment environment v6.4

Once you have created and configured your new deployment project, you can create environments for it to deploy to. Bamboo allows you to create multiple deployment environments and also allows you to manage:

- Environment details such as name and description
- Tasks
- Triggers
- Permissions
- Agents
- Notifications
- Variables

To create a new deployment environment you will need to:

1. Provide a name that represents your environment e.g. Test or Production
2. Provide a description that describes the function of your environment.

On this page:

- Creating a new deployment environment
- Using the deployment environment panel
- Editing the environment details

Related pages:

- Tasks for deployment environments
- Triggers for deployment environments
- Agents for deployment environments
- Notifications for deployment environments
- Variables for deployment environments
- Permissions for deployment environments
- Requirements for deployment environments

Deployment environments are added from the Deployment project configuration screen.
Creating a new deployment environment

1. From the Bamboo menu bar, click Deploy > All Deployment Projects.
2. Click the edit icon ( ) for the deployment project you want to edit.
3. In the "Deployment project configuration" screen, click Add environment.
4. Provide your deployment environment details.
5. Select if you want to run your deployment in the agent environment or in a docker container. See Docker Runner.
6. Click on Create.

Your newly created environment appears with a red exclamation mark because no tasks have been defined for this environment yet.
See Tasks for deployment environments for more information on task configuration.

**Using the deployment environment panel**

All deployment environments are managed from the Deployment project configuration screen. By default, when the screen loads, each environment panel is displayed in its collapsed state. Click **Edit** to expand the deployment environment panel:

When expanded, the environment panel shows three separate sub-panels:

The three sub-panels provide the following functionality:

<table>
<thead>
<tr>
<th>Sub-panel</th>
<th>Functionality</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment</td>
<td>• Deploy&lt;br&gt;• Actions&lt;br&gt;• Minimize</td>
<td>• Manually deploys to the environment&lt;br&gt;• Allows the user to View, Delete or Move down the environment&lt;br&gt;• Minimize the environment panel back to its collapsed state</td>
</tr>
<tr>
<td>How you want to deploy</td>
<td>• Edit tasks</td>
<td>• Allows the user to edit the tasks associated with the environment</td>
</tr>
<tr>
<td>Other settings</td>
<td>• Triggers&lt;br&gt;• Environment permissions&lt;br&gt;• Agents assignment&lt;br&gt;• Notifications&lt;br&gt;• Variables</td>
<td>A set of optional settings that make your Bamboo deployments run more smoothly</td>
</tr>
</tbody>
</table>

**Editing the environment details**

Bamboo allows you to change both the environment name and the description. To edit these details:

1. Expand the environment panel and click the pencil icon next to the environment name. The 'Update environment' screen will display:

2. Complete the 'Update deployment project' screen using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment name</td>
<td>Dev Sandbox</td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td>Sandboxed development environment</td>
<td></td>
</tr>
</tbody>
</table>
3. Click **Save environment** to save your changes.

### Creating a deployment environment v5.14

Once you have created and configured your new deployment project, you can create environments for it to deploy to. Bamboo allows you to create multiple deployment environments and also allows you to manage:

- Environment details such as name and description
- Tasks
- Triggers
- Permissions
- Agents
- Notifications
- Variables

To create a new deployment environment you will need to:

1. Provide a name that represents your environment e.g. Test or Production
2. Provide a description that describes the function of your environment.

#### On this page:

- Creating a new deployment environment
- Using the deployment environment panel
- Editing the environment details

#### Related pages:

- Tasks for deployment environments
- Triggers for deployment environments
- Agents for deployment environments
- Notifications for deployment environments
- Variables for deployment environments
- Permissions for deployment environments
- Requirements for deployment environments

Deployment environments are added from the Deployment project configuration screen:

![Deployment project configuration screen](image)

### Creating a new deployment environment

To create a new deployment environment:

1. Click the blue **Add environment** button from the ‘Deployment project configuration’ screen. The ‘Set up environment’ screen will display:
1. Complete the 'Set up deployment project' screen using the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Optional?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment name</td>
<td>The name of the environment</td>
<td>✗</td>
</tr>
<tr>
<td>Description</td>
<td>A brief description of your deployment project</td>
<td>🟢</td>
</tr>
</tbody>
</table>

2. Click on Create and back to create the environment and return to the 'Deployment project configuration' screen.

Note: Because no tasks have been defined for this environment, it will appear with a red exclamation mark:

3. Alternatively, click on Continue to task setup to continue to task setup for your new environment:
Using the deployment environment panel

All deployment environments are managed from the Deployment project configuration screen. By default, when the screen loads, each environment panel is displayed in its collapsed state. Click **Edit** to expand the deployment environment panel:

When expanded, the environment panel shows three separate sub-panels:

The three sub-panels provide the following functionality:

<table>
<thead>
<tr>
<th>Sub-panel</th>
<th>Functionality</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment</td>
<td>• Deploy&lt;br&gt;• Actions&lt;br&gt;• Minimize</td>
<td>• Manually deploys to the environment&lt;br&gt;• Allows the user to View, Delete or Move down the environment&lt;br&gt;• Minimize the environment panel back to its collapsed state</td>
</tr>
<tr>
<td>How you want to deploy</td>
<td>• Edit tasks</td>
<td>• Allows the user to edit the tasks associated with the environment</td>
</tr>
<tr>
<td>Other settings</td>
<td>• Triggers&lt;br&gt;• Environment permissions&lt;br&gt;• Agents assignment&lt;br&gt;• Notifications&lt;br&gt;• Variables</td>
<td>A set of optional settings that make your Bamboo deployments run more smoothly</td>
</tr>
</tbody>
</table>

Editing the environment details

Bamboo allows you to change both the environment name and the description. To edit these details:

1. Expand the environment panel and click the pencil icon next to the environment name. The 'Update environment' screen will display:

   **Field**
   
   **Description**
   
   **Optional?**

2. Complete the 'Update deployment project' screen using the following fields:

See Tasks for deployment environments for more information on task configuration.
Managing deployment projects

Bamboo makes it easy to monitor and manage your deployment projects.

A single dashboard allows you to monitor deployment environments, deployment status, releases and time/date stamps. It also allows you to edit and deploy your projects.

On this page:
- Manage deployment projects
- View a particular deployment project
  - Project summary
  - Releases

Manage deployment projects

Deployment projects are viewed and managed from the 'All deployment projects' screen. Think of this as a dashboard for all your deployment projects.

Choose Deploy > All deployment projects from the Bamboo header:

The project list includes the following useful information:

Name
The name of the deployment project.

Environment
The environment the release was deployed to.

Release
The release artifact that Bamboo deployed, or attempted to deploy, to that environment.

Result
The result of the deployment, and a link to the associated logs.

Completed
The time and date stamp of the deployment, or the time spent deploying so far.

Actions
Actions you can perform: Edit and Deploy

Broken deployments are indicated by a vertical red line beside the environment name and a red deployment icon.

View a particular deployment project

You can drill down into an individual deployment project from the 'All deployment projects' screen (described above) by clicking on the name.
of a project. You can check on the following:

- Associated environments
- Release history
- Project artifacts details

**Project summary**

The **Project summary** tab shows the status of the environments associated with the deployment project:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Release branch</th>
<th>Result</th>
<th>Completed</th>
<th>Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dogfooding 2.12 branch</td>
<td>atlassian-plugins-release-5.7</td>
<td>Logs</td>
<td>25 Sep 2013 07:07 AM</td>
<td></td>
</tr>
<tr>
<td>Dogfooding 2.13 branch</td>
<td>Atlassian Plugins 2.13-3_(108)</td>
<td>Logs</td>

</tr>
</tbody>
</table>

The project list includes the following useful information:

**Name**
The name of the deployment project.

**Environment**
The environment the release was deployed to.

**Release**
The release artifact that Bamboo deployed, or attempted to deploy, to that environment.

**Result**
The result of the deployment, and a link to the associated logs.

**Completed**
The time and date stamp of the deployment, or the time spent deploying so far.

**Actions**
Actions you can perform: Edit and Deploy

Broken deployments are indicated by a vertical red line beside the environment name and a red deployment icon.

View a particular deployment project

You can drill down into an individual deployment project from the 'All deployment projects' screen (described above) by clicking on the name of a project. You can check on the following:

- Associated environments
- Release history
- Project artifacts details
## Project summary

The **Project summary** tab shows the status of the environments associated with the deployment project:

### Details include:

- **Environment**
  The environment the release was deployed to.

- **Release**
  The release artifact that Bamboo deployed, or attempted to deploy, to that environment.

- **Result**
  The result of the deployment, and a link to the associated logs.

- **Completed**
  The time and date stamp for the deployment, or the time spent deploying so far.

- **Actions**
  Actions you can perform: **Edit** and **Deploy**

### Releases

The **Releases** tab provides details of the currently deployed release and the history of previous releases associated with the deployment project:

#### Currently deployed

</tr>
</tbody>
</table>

#### Release details include:

- **Version**
  The name of the release artifact.

- **Release branch**
  The branch the release was derived from.

- **Flagged**
  Any flags that have been applied to the release. Values are *Broken* and *Approved*. Neutral flags remain blank.

- **Created**
  The time and date stamp for when the release was created.
Manually starting a deployment

Bamboo can start deployments either by automated triggers, or by starting the process manually. Manually executing the deployment gives you the ability to start the process at your convenience, without having to wait for a scheduled event or trigger to take place.

On this page:

- Manually starting a deployment

Manually starting a deployment

Deployment projects can be viewed and managed from the ‘All deployment projects’ screen. Think of this as a dashboard view of all of your deployment projects. You can also start deployments from this screen.

To manually start a deployment

1. From the ‘All deployment projects’ screen, click on the associated Deploy icon:

   The ‘Deployment preview’ screen will display:

   ![Deployment preview screen](image)

   The deployment preview screen comprises a left hand ‘settings’ side and a right hand preview and information side. Bamboo will attempt to display a preview or information to reflect the choices made on the settings side.

2. Using the radio buttons, decide if you wish to create a new release from a build result or promote an existing release to the deployment environment.
3. If creating a new release from a build result:
   a. Check the Create new release from build result radio button
   b. Select the Plan branch you wish to use:

   ![Create new release screen](image)

   c. Select the Build result you wish to use:
You can only choose results from successful builds, and since (and including) the last release created on this particular branch.

d. Check that the name of your release is correct:

If you need more information about where the default name comes from, click on the ‘i’ icon.

e. Click Start deployment

4. If promoting an existing release:
   a. Check the Promote existing release to this environment radio button
   b. Select the Plan branch you wish to promote (optional):

   c. Select the release that you wish to promote:
d. Click **Start deployment**

### Deployments from branches

**What are branch deployments?**

Branching is an important tool in your development process, as it offers a very powerful way to let developers work in isolation on different aspects of a software project.

**Plan branches** represent a build for a branch in the version control system. The plan branch inherits all of the configuration defined by the parent plan, and any new branch created is automatically built and tested using the same build configuration as the parent. When the plan branch build succeeds, it can be automatically or manually merged back into master.

Branch deployments extend plan branches by allowing users to create a deployment release from any plan branch. Learn more about branching strategies: [Bamboo Best Practice - Branching and DVCS](#)

#### On this page:

- What are branch deployments?
- Why should we use branch deployments?
- Branch deployment use cases
  - Manual branch deployment
  - Automated branch deployment

#### Related pages:

- Understanding deployment releases

- Triggers for deployment environments

**Why should we use branch deployments?**

Bamboo deployments allow a plan branch to be deployed to a non-critical test environment before the feature code is merged back to master. This means that the feature code can be thoroughly tested and evaluated in a real server environment before the developer merges back the changes to master.

Developers should consider using branch deployments whenever they want to keep their in-progress development code separate from the master code, but want to test it within a deployable environment.

Learn more about [deployment releases](#) and how [deployment releases work](#).

The following diagram shows a typical deployment branch example.

1. The developer creates a new branch off of the master and a plan branch is automatically created for the new branch in Bamboo
2. The developer commits code against the branch and the plan branch automatically builds the changes
3. Following a successful build, they then deploy the results of builds #3 and #4 into a test environment for thorough testing
4. When satisfied that all of the tests have been passed, the developer manually merges their feature branch back into master
5. Now that the changes are in master – sporting the new feature – a new release can be created and deployed to the mainline environments (e.g. QA, Staging and Production).
Branch deployment use cases

Branch deployments should only ever be triggered into safe testing environments - they should never be triggered into production-like environments such as Staging, QA or Production.

Learn more about Creating and configuring a deployment project.

There are two typical strategies for managing branch deployments:

1. Manual branch deployment
2. Automated branch deployment

Let's examine each strategy in more detail.

**Manual branch deployment**

Let's assume a developer is using a plan branch to work on a new feature for a product. They reach a point in development where the new code needs testing in a server environment.

1. The developer successfully builds and tests the code using Bamboo. Let's call this Build #1
2. When a successful build occurs, it's ready to deploy by creating a new release for Build #1 and deploying it to the testing environment

Execute deployment: Regula 1

Release details

Please select a release to deploy

Current release on Regula 1

never been deployed to

Execution

Tasks to run

1. Artifact downloaded - Download release contents
2. Script

Estimated time

unknown

Eligible agents

34 agents and 18 elastic images

Start deployment  Cancel
3. When deployed, the developer thoroughly tests their new code. When satisfied that all of the tests have been passed, the developer can merge the changes back into master.

Learn more about Manually starting a deployment.

**Automated branch deployment**

Let's consider another developer who is also using a plan branch to work on a new feature for the product. They decide to automate the branch deployment so that it isn't triggered manually.

1. The developer successfully builds the code, including the new code they have been working on. Let's call this Build #2
2. The developer doesn't want to deploy manually, so uses Bamboo's automated triggering to set up a strategy to deploy the plan branch into a deployment test environment. Two options are available:
   a. use Bamboo's cron based scheduling to deploy at a specified time and date:

   ![Trigger configuration](image)

   b. use Bamboo to trigger a deployment upon the successful completion of a build plan:

   ![Trigger configuration](image)

3. The developer sets up the triggering strategy to best match working practices. Once the trigger is reached, the plan branch build is deployed to the test environment
4. When deployed, the developer thoroughly tests their new code. When satisfied that all of the tests have been passed, the developer can merge the changes back into master.

**Remember**: Plan branch code should only be merged back to master AFTER testing of the branch feature code is complete AND successful.

Learn more about Triggers for deployment environments.

**Configuring project permissions**
Starting from version 6.2, Bamboo allows you to set up permission on the project-level.

You must be an **Administrator** or **Project administrator** to be able to edit permissions on the project-level.

---

**To change project permissions:**

1. From the header bar, click **Projects**.
2. Click on the project you want to set permissions for.
3. In the upper-right corner, click **Project settings > Project permissions**.
4. Search for a user or a group you want to grant permissions.
5. From the **Select permissions** drop-down, select the permission type and click **Add**.

---

### Configuring project permissions v6.2

Starting from version 6.2, Bamboo allows you to set up permission on the project-level.

You must be an **Administrator** or **Project administrator** to be able to edit permissions on the project-level.

---

**To change project permissions:**

1. From the header bar, click **Projects**.
2. Click on the project you want to set permissions for.
3. In the upper-right corner, click **Project settings > Project permissions**.
4. Search for a user or a group you want to grant permissions.
5. From the **Select permissions** drop-down, select the permission type and click **Add**.
Getting feedback

Getting immediate feedback about build results is the essence of continuous integration. Furthermore, getting reports on activity of your development team can give you deep insights into your process efficiencies and schedule risks.

Notifications

Bamboo can send notifications to your team about the success or failure of their builds in a number of ways:

- The Wallboard
- Email
- RSS feeds
- Instant messaging

Reports

Bamboo provides various reports about the build activity of your development team:

- Summary statistics for all users
- Build results for an author
- Comparison charts for authors
- Comparison charts for plans
- Clover code-coverage for a job
- Clover code-coverage for a build

Notifications

Bamboo can send notifications about build results so that you can find out immediately about the success or failure of your builds.

You can get notifications in different ways:

- **Bamboo Wallboard**
  Show build results on a dedicated monitor.
  See Displaying the wallboard.

- **Email (e.g. GMail)**
  Get build results in your inbox.
  See Configuring notifications.

- **Instant messaging (e.g. Hipchat, Google Talk)**
  Send notifications to your dev chat room.
See Configuring notifications.

**RSS feeds**
Get aggregated key information about your builds.

See Subscribing to RSS feeds.

See also Changing your notification preferences.

### Displaying the wallboard

A development team can benefit from setting up a dedicated monitor to display Bamboo’s latest build results using the Bamboo wallboard.

The Bamboo wallboard can display the latest results for:

- all plans that you have permission to see.
- just your favorite plans.
- plans filtered by plan label.

The **branches wallboard** displays the status of all the branches and the plan that the branches belong to.

![Bamboo wallboard](image)

**On this page:**
- How do I do that?
- Notes

**Related pages:**
- Getting feedback
- Using the Bamboo Dashboard

#### How do I do that?

Log in to Bamboo, if necessary.

Go to the Dashboard.

<table>
<thead>
<tr>
<th>Task</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>All plans</td>
<td>Wallboard &gt; All Plans</td>
<td>Alternatively, use the following URL in your browser, replacing 'bambooserver' with the real name of your Bamboo server:  <a href="http://bambooserver:8080/bamboo/telemetry.action">http://bambooserver:8080/bamboo/telemetry.action</a></td>
</tr>
<tr>
<td>Favorite plans</td>
<td>Wallboard &gt; Favorite Plans</td>
<td>Only users who have logged in to Bamboo can specify and access favorites. Alternatively, use the following URL in your browser, replacing 'bambooserver' with the real name of your Bamboo server:  <a href="http://bambooserver:8080/bamboo/telemetry.action?filter=favorites">http://bambooserver:8080/bamboo/telemetry.action?filter=favorites</a></td>
</tr>
<tr>
<td>Filtered plans</td>
<td>Wallboard &gt; Filtered Plans</td>
<td>You need to have set up a plan filter first. See Using the Bamboo Dashboard.</td>
</tr>
</tbody>
</table>
Notes

- You will only be able to display those plans that you have permission to see.
- Once you are viewing the wallboard in your browser window, set your browser to 'full screen' mode to make the wallboard fill your entire screen. (Use F11 for common browsers on Windows and UNIX/Linux-based systems and Shift+Cmd+F for Firefox on Mac OS X.)
- If you are going to display the wallboard permanently, you may want to ask your Bamboo administrator to create a user who has only a limited set of permissions.
- If your wallboard is displayed on a touchscreen (such as an iPad) or its content can be accessed with a 'human interface device', such as a mouse, then touching or clicking a build result on the wallboard shows more information about that build.

Screenshot: More information from a build result on the wallboard

✅ Acceptance Test JDK 1.6

Bamboo
12 hours ago

Tests: 203 passed
Duration: 71 minutes
Changes:
Who: Marcin Gardias
Why: BAM-7227 - Not Built Chains should be shown on the build history tab

Who: Przemyslaw Bruski
Why: BAM-6835 - Performance degradation with EC2 agents

Configuring notifications for a plan and its jobs

Notifications in Bamboo are triggered by a range of events involving a plan and its jobs, including build completion, build outcomes and comments being posted against build results. You can configure whether notifications are sent for a particular event for each plan and job, and who they are sent to.

Bamboo users can choose whether to receive their notifications via email, IM, both or neither. In general, recipients do not require Bamboo user accounts.

Adding notifications for a plan or job

Before you begin:

- You must have the 'Edit' permission for a plan, to add or remove notifications for it.

- You need to configure Bamboo’s SMTP email and/or instant messaging capabilities before Bamboo can send notifications. If you have not configured either or both of these, a note will display on the page prompting you to set up the appropriate server(s):
  - To configure an email server for Bamboo, click Add an Email Server in the note and enter the email server details in the window that displays. See Configuring Bamboo to send SMTP Email for more information.
  - To configure an instant messaging server for Bamboo, click Add an Instant Messaging Server in the note and enter the instant messaging server details in the window that displays. See Configuring Bamboo to use Instant Messaging for more information.
To add a notification for a plan or its jobs:

1. Navigate to the configuration for the desired plan, as described on Configuring plans.
2. Click the Notifications tab.
3. Set up a new notification in the 'Add Build Notification' section as follows:
   a. Event
      Select the event type you want to be notified about. Refer to the list of events (below) for details.
   b. Recipient Type
      i. User — Enter the username of the appropriate Bamboo user, or click the icon to select from a list of users.
      ii. Hipchat — Enter the Hipchat API Token and Room Name. See Integrating Bamboo with Hipchat for more information.
      iii. Group — Enter the name of the appropriate Bamboo group(s).
      iv. Email Address — You can use email to send notifications to a person who is not a Bamboo user. Type the appropriate email address. Note that:
         • If you specify the email address of an existing Bamboo user, the user will receive notifications even if they have elected not to receive notifications in their user preferences.
      v. IM Address — This is useful if you need to send Instant Messenger (IM) notifications to a person who is not a Bamboo user. Type the appropriate IM address. Note that:
         • If you specify a broadcast address (eg. 'project-x@broadcast.chat.mycompany.com'), Bamboo will not know the context of related IM responses.
         • If you specify the IM address of an existing Bamboo user, the user will receive notifications even if they have elected not to receive notifications in their user preferences.
      vi. Responsible Users — The Bamboo users who have been assigned as being responsible for a broken build. See Assigning responsibility for build failures.
      vii. Committers — The Bamboo users who have committed code to a particular build since build was last checked out by Bamboo.
         Committers are notified based on the notification preferences of a Bamboo user associated with the commit's author and email, also known as source repository alias. If there's no user linked to the source repository alias, Bamboo will not be able to send notifications.
      viii. Watchers — The Bamboo users who have marked this plan as one of their favorites.
4. Click Add, then configure further notifications if required.
5. Click Save when you have finished.

Screenshot: Plan build notifications

Notification events

Plan Events

All Builds Completed
Bamboo will send a notification whenever the plan build finishes, regardless of the plan build's result. This notification is recommended for any plans whose latest build activity is critical for people to be informed about.

This is a good plan-based notification to use if you are new to Bamboo. You can change it to a less obtrusive notification option as you become more confident with continuous integration and Bamboo's build processes.

Change of Build Status
Bamboo will send a notification only when there has been a change in status of the plan's build activity over consecutive plan builds — for example, only whenever a plan's latest build changes from successful to failed or vice versa (i.e. 'fixed').

This notification option is less obtrusive than the other plan notifications mentioned above.

Failed Builds And First Successful
Bamboo will send a notification whenever:
- a build of this plan fails.
- the plan is 'fixed' (that is, the plan's latest build is successful and the previous plan build failed).

This notification is generally suitable for the majority of plans.

**After X Failed Builds**
This notification allows you to specify the Number Of Failures (i.e. number of failed builds of this plan), after which Bamboo will send a notification.

This notification option minimizes the number of messages sent by Bamboo if the plan's builds fail on a frequent basis. You can also use this event to escalate plan build problems, for example, to notify a manager when a plan build fails five times.

**Comment Added**
Bamboo will send a notification whenever a comment is added to a build result. The email notification will contain all comments against the plan build, whereas IM notifications will only contain the comment that triggered this notification event.

This notification can help improve collaboration between team members. Be aware that you will not receive notifications for any comments which you post yourself.

**Change of Responsibilities**
Bamboo will send a notification whenever someone is added to, or removed from, the list of those responsible for a broken build.

This notification can help improve collaboration between team members.

**Job Events**

**All Jobs Completed**
Bamboo will send a notification whenever a job build of the plan finishes, regardless of the job build's result. This notification is recommended if the latest build activity of all jobs in this plan are critical for people to be informed about.

This is a good job-based notification to use if you are new to Bamboo. You can change it to a less obtrusive notification option as you become more confident with continuous integration and Bamboo's build processes.

**Change of Job Status**
Bamboo will send a notification only when there has been a change in build activity status of the jobs within this plan over consecutive plan builds — for example, only whenever the latest build of any job in this plan changes from successful to failed or vice versa (i.e. 'fixed').

This notification option is less obtrusive than the other job notifications mentioned above.

**Failed Jobs And First Successful**
Bamboo will send a notification whenever:
- a build of this job fails.
- the job is 'fixed' (that is, the job's latest build is successful and the previous job build failed).

**First Failed Job For Plan**
If multiple jobs fail in a plan, Bamboo will only send a notification for the first failing job detected by the Bamboo system.

This is a less obtrusive notification option that informs about a failing job (and hence, plan) in the shortest possible time.

**Job Error**
Bamboo will send a notification whenever an error occurs in one of the plan's job build processes (i.e. the activities that Bamboo performs to run a job build). This event is not related to failures of the actual build itself (see the Failed Jobs And First Successful and Failed Builds And First Successful events above). For example, a notification will be sent if Bamboo encounters an error when connecting to the repository, or detecting changes.

**Job Hung**
Bamboo will send a notification whenever it determines that one of the plan's job builds has hung, according to the hung job build criteria (read more about configuring your hung job build settings).

Use this notification to ensure that the relevant people are informed when a job build becomes unresponsive.

**Job Queue Timeout**
Bamboo will send a notification whenever one of the plan's job builds has been waiting in the queue for longer than the build queue timeout criteria (read more about configuring your job's Build Queue Timeout settings).

Use this notification to ensure that the relevant people are informed when a job build is stuck in the build queue for too long.

**Job Queued Without Capable Agents**
Bamboo will send a notification whenever one of the plan's job builds is queued and there are no agents capable of building it.

Use this notification to ensure that people are notified when changes to agents adversely affect your job's builds.

Removing notifications from a plan or job
You must have the 'Edit' permission for a plan, to add or remove notifications for it.

1. Navigate to the configuration for the desired Plan, as described on Configuring plans.
2. Click the Notifications tab.
3. Click Remove for each of the notifications that you wish to remove.

Configuring Bamboo to send SMTP Email
Bamboo can send email notifications about its build results. There are two steps to setting this up:

1. Configure Bamboo to send SMTP email (see below).
2. Configure a plan to send SMTP email notifications about build results (see Configuring notifications for a plan and its jobs).
Configuring Bamboo to send SMTP email

To configure Bamboo to send SMTP email:

1. Click the [icon] in the Bamboo header and choose Overview.

2. Click Mail Server in the left navigation column (under 'Communication'). This will display the 'Mail Server Details' page (see screenshot below).

3. Edit the mail server settings as necessary:

   **Name**
   A display-name for the email address e.g. ‘SMTP Server’

   **From Address**
   The email address from which Bamboo notifications will be sent.

   **Subject Prefix**
   The text (if any) which will be added to the start of the email subject line. For example '[Bamboo]' will result in emails with subjects like:
   - [Bamboo] TEST build 1,001 has FAILED (77 tests failed, no failures were new) : Change made by jsmith
   - [Bamboo] TEST build 1,002 was SUCCESSFUL (with 77 tests) : Change made by jsmith

   **Email Settings**
   Choose either SMTP or JNDI. See the Notes about JNDI below.

   **SMTP Server**
   The address of the email server that Bamboo will use to send notifications e.g. 'mail.myserver.com'.

   **Username**
   The login name of the account that Bamboo will use to login to the SMTP server.

   **JNDI Location**
   Depends on your application server, and on the location of the 'mail' resource within the JNDI tree you specify. E.g. 'java:comp/env/mail/BambooMailServer'.

4. Type a test email address in the [Test Recipient Address] box.
5. Click Test, and verify that a test email is received.
6. Click Save.

Screenshot: Email Server Details
1. Install Bamboo.
2. Make sure that the following files are copied to and exists only in `<Bamboo-Install>/lib`:
   - `javax.mail-X.X.X.jar`
   - `javax.mail-api-X.X.X.jar` (only if you're using Bamboo 6.0 or later)

   • If the `javax.mail-X.X.X.jar` and `javax.mail-api-X.X.X.jar` files don't exist in the `<Bamboo-Install>/lib` directory, you must move the `javax` files installed at `<Bamboo-Install>/atlassian-bamboo/WEB-INF/lib` to `<Bamboo-Install>/lib`.
   • If the `javax.mail-X.X.X.jar` and `javax.mail-api-X.X.X.jar` files already exist in the `<Bamboo-Install>/lib` directory, simply delete the `javax` files shipped with Bamboo in `<Bamboo-Install>/atlassian-bamboo/WEB-INF/lib`.

   In Bamboo 5.9 the `mail-X.X.jar` and `activation-X.X.jar` files were included in the download archive. Starting with Bamboo 5.10:
   • The `mail-X.X.jar` file has been renamed to `javax.mail-X.X.X.jar` and must be moved to `<Bamboo-Install>/lib`
   • The `activation.jar` file is not required

3. Add the following configuration to your `BambooInstall/conf/server.xml` file:
Configure Bamboo to use a JNDI Location of `java:comp/env/mail/GmailSmtpServer`. Note that the JNDI Location is case sensitive and must match the resource name specified in `server.xml`.

**Notes**

You can use a mail session as an alternative to specifying mail details directly in Bamboo. You configure the mail session in your application server (e.g. in the `server.xml` file — see Locating important directories and files), and then use JNDI to look up the preconfigured mail session. JNDI has the following advantages:

- **Centralized management** - mail details are configured in the same place as database details, and may be configured through your application server administration tools.
- **Better security** - mail details are not available to Bamboo administrators through the Bamboo interface, and aren’t stored in Bamboo backup files.
- **More SMTP options** - e.g. SSL. If you want to use SMTP over SSL you will need to use JNDI.

**Configuring Bamboo to send SMTP Email v5.14**

Bamboo can send email notifications about its build results. There are two steps to setting this up:

1. Configure Bamboo to send SMTP email (see below).
2. Configure a plan to send SMTP email notifications about build results (see Configuring notifications for a plan and its jobs).

On this page:

- Configuring Bamboo to send SMTP email
- Configuring email notifications for Gmail

**To configure Bamboo to send SMTP email:**

1. Click the ![icon](icon) icon in the Bamboo header and choose **Overview**.
2. Click **Mail Server** in the left navigation column (under ‘Communication’). This will display the ‘Mail Server Details’ page (see screenshot below).
3. Edit the mail server settings as necessary:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A display-name for the email address e.g. ‘SMTP Server’</td>
</tr>
<tr>
<td>From Address</td>
<td>The email address from which Bamboo notifications will be sent.</td>
</tr>
</tbody>
</table>
Subject Prefix | The text (if any) which will be added to the start of the email subject line. For example '[Bamboo]' will result in emails with subjects like:
- [Bamboo] TEST build 1,001 has FAILED (77 tests failed, no failures were new) : Change made by jsmith
- [Bamboo] TEST build 1,002 was SUCCESSFUL (with 77 tests) : Change made by jsmith

Email Settings | Choose either SMTP or JNDI. See the Notes about JNDI below.

SMTP Server | The address of the email server that Bamboo will use to send notifications e.g. 'mail.myserver.com'.

Username | The login name of the account that Bamboo will use to login to the SMTP server.

Password | The password of the account that Bamboo will use to login to the SMTP server.

JNDI Location | Depends on your application server, and on the location of the 'mail' resource within the JNDI tree you specify. E.g. 'java:comp/env/mail/BambooMailServer'.

4. Type a test email address in the Test Recipient Address box.
5. Click Test, and verify that a test email is received.
6. Click Save.

Screenshot: Email Server Details

Configuring email notifications for Gmail
Gmail.com uses TLS (SSL). A JNDI connector needs to be configured. Unfortunately Bamboo does not yet support JNDI with TLS.

**To enable Gmail as your mail server:**

1. Install Bamboo.
2. Add the following configuration to your BambooInstall/conf/server.xml file:

   ```xml
   <Context path="/bamboo" docBase="${catalina.base}/atlassian-bamboo" reloadable="true">
     <Resource name="mail/GmailSmtpServer" auth="Container"
       type="javax.mail.Session"
       mail.smtp.host="smtp.gmail.com"
       mail.smtp.port="465"
       mail.smtp.auth="true"
       mail.smtp.user="<your-name>@gmail.com"
       mail.smtp.starttls.enable="true"
       mail.smtp.socketFactory.class="javax.net.ssl.SSLSocketFactory"
     />
   </Context>
   ``

Make sure that the `javax.mail-X.X.X.jar` file exists only in `<Bamboo-Install>/lib`.  

- If the `javax.mail-X.X.X.jar` file doesn't exist in the `<Bamboo-Install>/lib` directory, you must move the `javax` file installed at `<Bamboo-Install>/atlassian-bamboo/WEB-INF/lib` to `<Bamboo-Install>/lib`.
- If the `javax.mail-X.X.X.jar` file already exists in the `<Bamboo-Install>/lib` directory, simply delete the `javax` file shipped with Bamboo in `<Bamboo-Install>/atlassian-bamboo/WEB-INF/lib`.

In Bamboo 5.9 the `mail-X.X.jar` and `activation-X.X.jar` files were included in the download archive. Starting with Bamboo 5.10:

- the `mail-X.X.jar` file has been renamed to `javax.mail-X.X.X.jar` and must be moved to `<Bamboo-Install>/lib`  
- the `activation.jar` file is not required

Configure Bamboo to use a JNDI Location of `java:comp/env/mail/GmailSmtpServer`. Note that the JNDI Location is case sensitive and must match the resource name specified in server.xml.

**Notes**

You can use a mail session as an alternative to specifying mail details directly in Bamboo. You configure the mail session in your application server (e.g. in the server.xml file — see Locating important directories and files), and then use JNDI to look up the preconfigured mail session. JNDI has the following advantages:

- **Centralized management** - mail details are configured in the same place as database details, and may be configured through your application server administration tools.
- **Better security** - mail details are not available to Bamboo administrators through the Bamboo interface, and aren’t stored in Bamboo backup files.
- **More SMTP options** - e.g. SSL. If you want to use SMTP over SSL you will need to use JNDI.

**Configuring Bamboo to send SMTP Email v6.0**

Bamboo can send email notifications about its build results. There are two steps to setting this up:

1. Configure Bamboo to send SMTP email (see below).
2. Configure a plan to send SMTP email notifications about build results (see Configuring notifications for a plan and its jobs).

**On this page:**

password="<your-pw>"
mail.smtp.starttls.enable="true"
  
  mail.smtp.socketFactory.class="javax.net.ssl.SSLSocketFactory"
  
</Context>

Configure Bamboo to use a JNDI Location of java:comp/env/mail/GmailSmtpServer. Note that the JNDI Location is case sensitive and must match the resource name specified in server.xml.

Notes
You can use a mail session as an alternative to specifying mail details directly in Bamboo. You configure the mail session in your application server (e.g. in the server.xml file — see Locating important directories and files), and then use JNDI to look up the preconfigured mail session. JNDI has the following advantages:

- **Centralized management** - mail details are configured in the same place as database details, and may be configured through your application server administration tools.
- **Better security** - mail details are not available to Bamboo administrators through the Bamboo interface, and aren't stored in Bamboo backup files.
- **More SMTP options** - e.g. SSL. If you want to use SMTP over SSL you will need to use JNDI.

### Configuring Bamboo to send SMTP Email v6.1

Bamboo can send email notifications about its build results. There are two steps to setting this up:

1. Configure Bamboo to send SMTP email (see below).
2. Configure a plan to send SMTP email notifications about build results (see Configuring notifications for a plan and its jobs).

#### On this page:
- Configuring Bamboo to send SMTP email
- Configuring email notifications for Gmail
- Notes

#### Related pages:
- Configuring notifications for a plan and its jobs

### Configuring Bamboo to send SMTP email

To configure Bamboo to send SMTP email:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Mail Server in the left navigation column (under 'Communication'). This will display the 'Mail Server Details' page (see screenshot below).
3. Edit the mail server settings as necessary:

   **Name**
   A display-name for the email address e.g. 'SMTP Server'

   **From Address**
   The email address from which Bamboo notifications will be sent.

   **Subject Prefix**
   The text (if any) which will be added to the start of the email subject line. For example "[Bamboo]" will result in emails with subjects like:
[Bamboo] TEST build 1,001 has FAILED (77 tests failed, no failures were new) : Change made by jsmith
[Bamboo] TEST build 1,002 was SUCCESSFUL (with 77 tests) : Change made by jsmith

**Email Settings**
Choose either **SMTP** or **JNDI**. See the Notes about JNDI below.

**SMTP Server**
The address of the email server that Bamboo will use to send notifications e.g. `mail.myserver.com`.

**Username**
The login name of the account that Bamboo will use to login to the SMTP server.

**JNDI Location**
Depends on your application server, and on the location of the 'mail' resource within the JNDI tree you specify. E.g. `java:comp/env/mail/BambooMailServer`.

1. Type a test email address in the **Test Recipient Address** box.
2. Click **Test**, and verify that a test email is received.
3. Click **Save**.

*Screenshot: Email Server Details*

**Configure mail server details**

**Configure mail server details**
What email settings should Bamboo use? Please enter either a SMTP server hostname, or the JNDI location of a javax.mail.Session object to use.

- **Name**: tardigrade-bamboo
  - Provide a name for this email server (this will be displayed on notification emails).
- **From address**: noreply@atlassian.com
  - This is the email address Bamboo-generated emails are sent from.
- **Subject prefix**: [Bamboo]
  - This is the tag added to the start of the subject line to identify Bamboo-generated email, e.g. [Bamboo].

- **Email settings**:
  - **SMTP**: Choose either a SMTP server or a JNDI location
  - **SMTP server**: smtpmyprod.prod.in.atlassian.com
    - Specify the email server used to send out the builds results. For example "mail.myserver.com".
  - **SMTP port**: 25
    - Specify the SMTP port (default to 25).
  - **Username**
  - **Password**

- **Use TLS**

**Test email configuration**

You can enter a test recipient email address below and click **Test**. Bamboo will test whether this email setting is valid by sending a test email to the specified address(es).

- **Test recipient address**
  - You can enter one (or more, comma separated) email address to which Bamboo will send a test email.
  - Click **Save**

*Configuring email notifications for Gmail*

Gmail.com uses TLS (SSL). A JNDI connector needs to be configured. Unfortunately Bamboo does not yet support JNDI with TLS.

**To enable Gmail as your mail server:**

1. Install Bamboo.
2. Make sure that the following files are copied to and exists only in `<Bamboo-Install>/lib`:
   - `javax.mail-X.X.X.jar`
   - `javax.mail-api-X.X.X.jar` (only if you're using Bamboo 6.0 or later)
3. Add the following configuration to your BambooInstall/conf/server.xml file:

```xml
<Context path="/bamboo" docBase="${catalina.base}/atlassian-bamboo"
    reloadable="true">
    <Resource name="mail/GmailSmtpServer" 
        auth="Container" 
        type="javax.mail.Session" 
        mail.smtp.host="smtp.gmail.com" 
        mail.smtp.port="465" 
        mail.smtp.auth="true" 
        mail.smtp.user="<your-name>@gmail.com" 
        password="<your-pw>" 
        mail.smtp.starttls.enable="true" 
        mail.smtp.socketFactory.class="javax.net.ssl.SSLSocketFactory"
    />
</Context>
```

Configure Bamboo to use a JNDI Location of `java:comp/env/mail/GmailSmtpServer`. Note that the JNDI Location is case sensitive and must match the resource name specified in server.xml.

**Notes**

You can use a mail session as an alternative to specifying mail details directly in Bamboo. You configure the mail session in your application server (e.g. in the server.xml file — see Locating important directories and files), and then use JNDI to look up the preconfigured mail session. JNDI has the following advantages:

- **Centralized management** - mail details are configured in the same place as database details, and may be configured through your application server administration tools.
- **Better security** - mail details are not available to Bamboo administrators through the Bamboo interface, and aren't stored in Bamboo backup files.
- **More SMTP options** - e.g. SSL. If you want to use SMTP over SSL you will need to use JNDI.

**Configuring Bamboo to use Instant Messaging**

Bamboo can send Instant Messaging (IM) notifications about its build results. There are two steps to setting this up:

1. Configure Bamboo to use Instant Messaging (see below).
2. Configure a plan to send IM notifications about its build results (see Configuring notifications for a plan and its jobs).

Please note, Bamboo supports XMPP protocol for messaging. This means Bamboo can be used with Gtalk or your enterprise XMPP server.

4. Click **Save**.

**Screenshot: Instant Messaging server details**

**Configuring Bamboo to use Google Talk for Instant Messaging**

If your Bamboo server has access to the internet, it can use **Google Talk** to send IM notifications about build results.

**Related pages:**
- Configuring notifications for a plan and its jobs
- Working with Instant Messenger (IM) Notifications

Before you begin:
- Google Talk does not allow IM messages to be received unless the receiver has approved the sender. Please ensure that the Gmail
user specified below is approved by each Google Talk recipient. That is, ensure that the 'Host' and 'Username' have previously sent messages to each other via Google Talk.

- The Google Talk service is hosted at talk.google.com. The default port is 5222. (Note: be aware that your firewall might be blocking traffic to this port.)
- TLS is required.
- The only supported authentication mechanism is SASL PLAIN. For additional information, please see: http://code.google.com/apis/talk/open_communications.html

To configure Bamboo to use Google Talk for Instant Messaging:

1. Click the icon in the Bamboo header and choose Overview.
2. Click IM Server in the left navigation panel (under 'Communication').
3. Click Edit. Modify the settings as required.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Type 'talk.google.com'. (If your IM Server uses an '@googlemail.com' account, type 'googlemail.com'.)</td>
</tr>
<tr>
<td>Port</td>
<td>Leave blank. Bamboo will perform a DNS lookup to figure out which port to use.</td>
</tr>
<tr>
<td>Username</td>
<td>Type the login name of the Google account from which IM notifications will be sent. Starting with Bamboo 3.4, you need to include the domain name, e.g. <a href="mailto:atlassianbamboo@gmail.com">atlassianbamboo@gmail.com</a> NOT atlassianbamboo.</td>
</tr>
<tr>
<td>Change password</td>
<td>Select this if you have specified a username different from the currently logged-in user.</td>
</tr>
<tr>
<td>Resource</td>
<td>An identifying name for the connection if multiple clients use the same jabber account.</td>
</tr>
<tr>
<td>Requires a TLS/SSL connection</td>
<td>Select this.</td>
</tr>
<tr>
<td>Force legacy SSL</td>
<td>test Recipient Address. You can test this configuration by entering an address and clicking Test.</td>

- TLS is required.
- The only supported authentication mechanism is SASL PLAIN. For additional information, please see: http://code.google.com/apis/talk/open_communications.html
If your Bamboo server has access to the internet, it can use Google Talk to send IM notifications about build results.

To configure Bamboo to use Google Talk for Instant Messaging:

1. Click the icon in the Bamboo header and choose Overview.
2. Click IM Server in the left navigation panel (under 'Communication').
3. Click Edit. Modify the settings as required.

   **Host**
   Type 'talk.google.com'. (If your IM Server uses an '@googlemail.com' account, type 'googlemail.com'.)

   **Port**
   Leave blank. Bamboo will perform a DNS lookup to figure out which port to use.

   **Username**
   Type the login name of the Google account from which IM notifications will be sent. Starting with Bamboo 3.4, you need to include the domain name, e.g. `atlassianbamboo@gmail.com` NOT `atlassianbamboo`.

   **Change password**
   Select this if you have specified a username different from the currently logged-in user.

   **Resource**
   An identifying name for the connection if multiple clients use the same jabber account.

   **Requires a TLS/SSL connection**
   Select this.

   **Force legacy SSL**
   Select this.

   **Test Recipient Address**
   You can test this configuration by entering an address and clicking Test.

4. Click Save.
Modifying notification templates

If you want to customize the layout and content of your Bamboo notifications, you can customize the templates for each of the notification types (i.e. HTML email, text email, instant message) and events (e.g. Build Commented). The notification templates are written in Freemarker:

Some content in notifications can also be configured via system properties, such as the number of log lines to include in email notifications that display log information.

Changes to notification templates only take effect after a Bamboo restart.

On this page:
- Modifying a notification template
- Configuring notifications content via system properties
- Notes

Related pages:
- Configuring Bamboo to use Instant Messaging

Modifying a notification template

To modify a notification template:

1. Locate the default notification templates in WEB-INF/classes/notification-templates/
2. Copy the notification template that you wish to modify into the templates/notification-templates folder of your Bamboo home directory, e.g. HOME/templates/notification-templates
3. Modify the copied template, as desired. Please see the section on Working with Freemarker below for tips on updating templates.
4. Save your changes to the template. You need to restart your Bamboo server for the template changes to take effect.

Working with Freemarker

The Bamboo notification templates are written in Freemarker. The Freemarker engine allows for dynamic content generation based on the Freemarker markup tags that are used in templates. This document does not describe the Freemarker language in detail. Please see the Freemarker Online Manual for full information on using this markup language.

Generating content via Freemarker involves merging a template (*.ftl file) with a context map. You can access any data in the context map from within the template using the Freemarker markup. For the notifications we have provided a specific subset of Bamboo objects that you can access. For example,

```
[#if buildSummary.successful]
${buildSummary.buildResultKey} was successful.
[/if]
```

If you had a successful Bamboo build with build result, BAM-1234-1, the above markup would return the following text in your notification:

BAM-1234-1 was successful.

You can find more information on working with Freemarker, including Bamboo objects available from Freemarker templates, tips on writing Freemarker templates and examples in the Freemarker and notification templates document.

Configuring notifications content via system properties

The following system properties can be configured to control some of the content that is included in notifications (e.g. the number of log lines to include in email notifications that display log information). For instructions on how to configure a system property, please refer to the Starting Bamboo page.

Before you begin:

The system properties below do not add content to notifications. You still need to ensure that your notification templates contain the relevant entities to display the content. For example, changing the bamboo.notifications.logLinesToInclude property will not add log information to your notifications. It only modifies the number of log lines displayed in notification templates that already include logs.

<table>
<thead>
<tr>
<th>System Property</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.notifications.logLinesToInclude</td>
<td>Specifies the number of log lines to include in email notifications that display log information.</td>
<td>100</td>
</tr>
</tbody>
</table>

Notes

- **Bamboo does not validate notification templates.** If you have incorrectly formatted the markup text in the template, Bamboo will still use the template to send out notifications. If this happens, your users may receive notifications with unreadable or missing information, as well as error messages. Errors will also be posted to your logs.

Freemarker and notification templates

Notification templates in Bamboo can be modified to customize the format and content of your notifications. The templates are written in Free.
Changes to notification templates only take effect after a Bamboo restart.

On this page:
- Accessing Bamboo data
- Special considerations when working with Freemarker
- Freemarker examples

Related pages:
- Configuring Bamboo to use Instant Messaging
- Modifying notification templates

Accessing Bamboo data

Each individual notification has a different subset of data that can be accessed from the Freemarker templates. You can find information on the objects available in our javadocs below.

- Build Completed Notification ("All Completed Builds" and "Failed and First Success")
- After X Failed Builds Notification
- Build Commented Notification
- Build Hung Notification
- Build Error Notification

Special considerations when working with Freemarker

Never assume data exists

Unfortunately Freemarker is not very forgiving if data does not exist or is null. Hence, you will need to check whether information exists before adding it to a page. The sample code below shows how you can validate for non-existent data.

```
[#if issue.jiraIssueDetails.summary?has_content] [/#if]
[#if issue.jiraIssueDetails.summary??] [/#if]
${issue.jiraIssueDetails.summary?if_exists}
${issue.jiraIssueDetails.summary!}
```

Check the encoding of your information

Freemarker has built-in utilities for escaping special characters. These could be characters that you deliberately do not want to be interpreted as HTML, or data that could potentially contain malicious content. The sample code below shows how you can escape characters in Freemarker.

```
${commit.comment?html} // for data to be encoded to be displayed as html
${commit.author?url} // for data to be encoded for a url
```

You can find more information on these utilities in the official Freemarker documentation.

Use white space carefully

When editing text email content and instant message content, you need to be very careful with spacing and line breaks. Any spaces and line breaks that you have entered in the Freemarker template will also exist in the evaluated content. Freemarker provides you with some utilities to remove white space, so that you can still retain some formatting in the templates.

More information can be found the official Freemarker documentation.

Freemarker examples

Below are some raw examples of additional information that you can add to your emails.

Please note, these examples are intended to demonstrate the use of Freemarker and how to access Bamboo objects. You will need to modify these examples to include your desired formatting and make it work with your data.

List files in a commit
Provide test error details

```text
[#if buildSummary.commits.size() > 0]
  [#list buildSummary.commits as commit]
    [#if commit_index gte 3][#break][#/if] //only shows 3 commits
    Author: <a href="[@ui.displayAuthorOrProfileLink commit.author/]">
      ${commit.author.fullName?html}
    </a>
    Comment: ${commit.comment?html}
    <br/>
    [#if commit.guessChangeSetId()?has_content]
    Revision: ${commit.guessChangeSetId()?html}
    <br/>
    [#if]
    [#if commit.files?has_content]
    Files:
      [#list commit.files as file]
        ${file.cleanName}    [#if file.revision?has_content](${file.revision})
      </a>
      </a>
      <a href="${baseUrl}${fn.getViewTestClassResultUrl(build.key, buildResults.buildNumber, testResultClass.name)}">
        ${testResultClass.shortName?html}
      </a> :
      <a href="${baseUrl}${fn.getViewTestCaseHistoryUrl(buildSummary.buildResultKey, testResult.className, testResult.actualMethodName)}">
        ${testResult.methodName?html}
      </a>:
      [#if testResult.errors?has_content]
        [#list testResult.errors as error]
          <pre>${error.errorMessage}</pre>  // a <pre/> tag is required to reserve formatting of error
        </pre>
      </list>
      [#list]
      [#list]
  [#else]
    This build does not have any commits.

```

1. Configuring notifications for a plan and its jobs v5.14

Notifications in Bamboo are triggered by a range of events involving a plan and its jobs, including build completion, build outcomes and comments being posted against build results. You can configure whether notifications are sent for a particular event for each plan and job, and who they are sent to.

Bamboo users can choose whether to receive their notifications via email, IM, both or neither. In general, recipients do not require Bamboo user accounts.

Adding notifications for a plan or job

Before you begin:

- You must have the ‘Edit’ permission for a plan, to add or remove notifications for it.

- You need to configure Bamboo’s SMTP email and/or instant messaging capabilities before Bamboo can send notifications. If you have not configured either or both of these, a note will display on the page prompting you to set up the appropriate server(s):
  - To configure an email server for Bamboo, click Add an Email Server in the note and enter the email server details in the window that displays. See Configuring Bamboo to send SMTP Email for more information.
  - To configure an instant messaging server for Bamboo, click Add an Instant Messaging Server in the note and enter the instant messaging server details in the window that displays. See Configuring Bamboo to use Instant Messaging for more information.

To add a notification for a plan or its jobs:

1. Navigate to the configuration for the desired plan, as described on Configuring plans.
2. Click the Notifications tab.
3. Set up a new notification in the ‘Add Build Notification’ section as follows:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event</td>
<td>Select the event type you want to be notified about. Refer to the list of events (below) for details.</td>
</tr>
</tbody>
</table>
| Recipient Type| **User** — Enter the username of the appropriate Bamboo user, or click the icon to select from a list of users.  
**Hipchat** — Enter the Hipchat API Token and Room Name. See Integrating Bamboo with Hipchat for more information.  
**Group** — Enter the name of the appropriate Bamboo group(s)  
**Email Address** — You can use email to send notifications to a person who is not a Bamboo user. Type the appropriate email address. Note that:  
- If you specify the email address of an existing Bamboo user, the user will receive notifications even if they have elected not to receive notifications in their user preferences. |

Related pages:
- Notifications
- Configuring plans
- Changing your notification preferences
- Granting plan permissions in bulk
IM Address—This is useful if you need to send Instant Messenger (IM) notifications to a person who is not a Bamboo user. Type the appropriate IM address. Note that:

- If you specify a broadcast address (e.g., 'project-x@broadcast.chat.mycompany.com'), Bamboo will not know the context of related IM responses.
- If you specify the IM address of an existing Bamboo user, the user will receive notifications even if they have elected not to receive notifications in their user preferences.

Responsible Users—The Bamboo users who have been assigned as being responsible for a broken build. See Assigning responsibility for build failures.

Committers—The Bamboo users who have committed code to a particular build since build was last checked out by Bamboo.

Committers are notified based on the notification preferences of a Bamboo user associated with the commit's author and email, also known as source repository alias. If there's no user linked to the source repository alias, Bamboo will not be able to send notifications.

Watchers—The Bamboo users who have marked this plan as one of their favorites.

4. Click Add, then configure further notifications if required.
5. Click Save when you have finished.

Screenshot: Plan build notifications

### Notification events

<table>
<thead>
<tr>
<th>Plan Events</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Builds Completed</td>
<td>Bamboo will send a notification whenever the plan build finishes, regardless of the plan build's result. This notification is recommended for any plans whose latest build activity is critical for people to be informed about. This is a good plan-based notification to use if you are new to Bamboo. You can change it to a less obtrusive notification option as you become more confident with continuous integration and Bamboo’s build processes.</td>
</tr>
<tr>
<td>Change of Build Status</td>
<td>Bamboo will send a notification only when there has been a change in status of the plan’s build activity over consecutive plan builds — for example, only whenever a plan's latest build changes from successful to failed or vice versa (i.e. “fixed”). This notification option is less obtrusive than the other plan notifications mentioned above.</td>
</tr>
<tr>
<td>Event Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Failed Builds And First Successful** | Bamboo will send a notification whenever:  
- a build of this plan fails.  
- the plan is 'fixed' (that is, the plan's latest build is successful and the previous plan build failed).  
✔️ This notification is generally suitable for the majority of plans. |
| **After X Failed Builds**          | This notification allows you to specify the Number Of Failures (i.e., number of failed builds of this plan), after which Bamboo will send a notification.  
✔️ This notification option minimizes the number of messages sent by Bamboo if the plan's builds fail on a frequent basis. You can also use this event to escalate plan build problems, for example, to notify a manager when a plan build fails five times. |
| **Comment Added**                  | Bamboo will send a notification whenever a comment is added to a build result. The email notification will contain all comments against the plan build, whereas IM notifications will only contain the comment that triggered this notification event.  
✔️ This notification can help improve collaboration between team members. Be aware that you will not receive notifications for any comments which you post yourself. |
| **Change of Responsibilities**    | Bamboo will send a notification whenever someone is added to, or removed from, the list of those responsible for a broken build.  
✔️ This notification can help improve collaboration between team members. |
| **Job Events**                     |                                                                                                                                                                                                        |
| **All Jobs Completed**             | Bamboo will send a notification whenever a job build of the plan finishes, regardless of the job build's result. This notification is recommended if the latest build activity of all jobs in this plan are critical for people to be informed about.  
✔️ This is a good job-based notification to use if you are new to Bamboo. You can change it to a less obtrusive notification option as you become more confident with continuous integration and Bamboo's build processes. |
| **Change of Job Status**           | Bamboo will send a notification only when there has been a change in build activity status of the jobs within this plan over consecutive plan builds — for example, only whenever the latest build of any job in this plan changes from successful to failed or vice versa (i.e., 'fixed').  
✔️ This notification option is less obtrusive than the other job notifications mentioned above. |
| **Failed Jobs And First Successful** | Bamboo will send a notification whenever:  
- a build of this job fails.  
- the job is 'fixed' (that is, the job's latest build is successful and the previous job build failed). |
| **First Failed Job For plan**      | If multiple jobs fail in a plan, Bamboo will only send a notification for the first failing job detected by the Bamboo system.  
✔️ This is a less obtrusive notification option that informs about a failing job (and hence, plan) in the shortest possible time. |
| **Job Error**                      | Bamboo will send a notification whenever an error occurs in one of the plan's job build processes (i.e., the activities that Bamboo performs to run a job build). This event is not related to failures of the actual build itself (see the Failed Jobs And First Successful and Failed Builds And First Successful events above). For example, a notification will be sent if Bamboo encounters an error when connecting to the repository, or detecting changes. |
| **Job Hung**                       | Bamboo will send a notification whenever it determines that one of the plan's job builds has hung, according to the hung job build criteria (read more about configuring your hung job build settings).  
✔️ Use this notification to ensure that the relevant people are informed when a job build becomes unresponsive. |
Job Queue Timeout

Bamboo will send a notification whenever one of the plan’s job builds has been waiting in the queue for longer than the build queue timeout criteria (read more about configuring your job’s Build Queue Timeout settings).

Use this notification to ensure that the relevant people are informed when a job build is stuck in the build queue for too long.

Job Queued Without Capable Agents

Bamboo will send a notification whenever one of the plan’s job builds is queued and there are no agents capable of building it.

Use this notification to ensure that people are notified when changes to agents adversely affect your job’s builds.

Removing notifications from a plan or job

You must have the ‘Edit’ permission for a plan, to add or remove notifications for it.

1. Navigate to the configuration for the desired Plan, as described on Configuring plans.
2. Click the Notifications tab.
3. Click Remove for each of the notifications that you wish to remove.

Configuring notifications for a plan and its jobs v6.1

Notifications in Bamboo are triggered by a range of events involving a plan and its jobs, including build completion, build outcomes and comments being posted against build results. You can configure whether notifications are sent for a particular event for each plan and job, and who they are sent to.

Bamboo users can choose whether to receive their notifications via email, IM, both or neither. In general, recipients do not require Bamboo user accounts.

Adding notifications for a plan or job

Before you begin:

On this page:
• Adding notifications for a plan or job
• Notification events
• Removing notifications from a plan or job

Related pages:
• Notifications
• Configuring plans
• Changing your notification preferences
• Granting plan permissions in bulk

You must have the ‘Edit’ permission for a plan, to add or remove notifications for it.

You need to configure Bamboo’s SMTP email and/or instant messaging capabilities before Bamboo can send notifications. If you have not configured either or both of these, a note will display on the page prompting you to set up the appropriate server(s):

• To configure an email server for Bamboo, click Add an Email Server in the note and enter the email server details in the window that displays. See Configuring Bamboo to send SMTP Email for more information.
• To configure an instant messaging server for Bamboo, click Add an Instant Messaging Server in the note and enter the instant messaging server details in the window that displays. See Configuring Bamboo to use Instant Messaging for more information.

To add a notification for a plan or its jobs:

1. Navigate to the configuration for the desired plan, as described on Configuring plans.
2. Click the Notifications tab.
3. Set up a new notification in the ‘Add Build Notification’ section as follows:
   a. Event
      Select the event type you want to be notified about. Refer to the list of events (below) for details.
   b. Recipient Type
      i. User — Enter the username of the appropriate Bamboo user, or click the icon to select from a list of users.
      ii. Hipchat — Enter the Hipchat API Token and Room Name. See Integrating Bamboo with Hipchat for more information.
      iii. Group — Enter the name of the appropriate Bamboo group(s).
      iv. Email Address — You can use email to send notifications to a person who is not a Bamboo user. Type the appropriate email address. Note that:
         • If you specify the email address of an existing Bamboo user, the user will receive notifications even if they have elected not to receive notifications in their user preferences.
v. **IM Address** — This is useful if you need to send Instant Messenger (IM) notifications to a person who is not a Bamboo user. Type the appropriate IM address. Note that:
   - If you specify a broadcast address (e.g. `project-x@broadcast.chat.mycompany.com`), Bamboo will not know the context of related IM responses.
   - If you specify the IM address of an existing Bamboo user, the user will receive notifications even if they have elected not to receive notifications in their user preferences.

vi. **Responsible Users** — The Bamboo users who have been assigned as being responsible for a broken build. See [Assigning responsibility for build failures](#).

vii. **Commiters** — The Bamboo users who have committed code to a particular build since build was last checked out by Bamboo.

Commiters are notified based on the notification preferences of a Bamboo user associated with the commit's author and email, also known as source repository alias. If there's no user linked to the source repository alias, Bamboo will not be able to send notifications.

viii. **Watchers** — The Bamboo users who have marked this plan as one of their favorites.

4. Click **Add**, then configure further notifications if required.
5. Click **Save** when you have finished.

**Notification events**

**Plan Events**

**All Builds Completed**
Bamboo will send a notification whenever the plan build finishes, regardless of the plan build's result. This notification is recommended for any plans whose latest build activity is critical for people to be informed about.

- This is a good plan-based notification to use if you are new to Bamboo. You can change it to a less obtrusive notification option as you become more confident with continuous integration and Bamboo's build processes.

**Change of Build Status**
Bamboo will send a notification only when there has been a change in status of the plan's build activity over consecutive plan builds — for example, only whenever a plan's latest build changes from successful to failed or vice versa (i.e. 'fixed').

- This notification option is less obtrusive than the other plan notifications mentioned above.

**Failed Builds And First Successful**
Bamboo will send a notification whenever:
- a build of this plan fails.
- the plan is 'fixed' (that is, the plan's latest build is successful and the previous plan build failed).

- This notification is generally suitable for the majority of plans.

**After X Failed Builds**
This notification allows you to specify the **Number Of Failures** (i.e. number of failed builds of this plan), after which Bamboo will send a notification.

- This notification option minimizes the number of messages sent by Bamboo if the plan's builds fail on a frequent basis. You can also use this event to escalate plan build problems, for example, to notify a manager when a plan build fails five times.

**Comment Added**
Bamboo will send a notification whenever a comment is added to a build result. The email notification will contain all comments against the plan build, whereas IM notifications will only contain the comment that triggered this notification event.

- This notification can help improve collaboration between team members. Be aware that you will not receive notifications for any comments which you post yourself.

**Change of Responsibilities**
Bamboo will send a notification whenever someone is added to, or removed from, the list of those responsible for a broken build.
This notification can help improve collaboration between team members.

**Job Events**

**All Jobs Completed**
Bamboo will send a notification whenever a job build of the plan finishes, regardless of the job build's result. This notification is recommended if the latest build activity of all jobs in this plan are critical for people to be informed about.

This is a good job-based notification to use if you are new to Bamboo. You can change it to a less obtrusive notification option as you become more confident with continuous integration and Bamboo's build processes.

**Change of Job Status**
Bamboo will send a notification only when there has been a change in build activity status of the jobs within this plan over consecutive plan builds — for example, only whenever the latest build of any job in this plan changes from successful to failed or vice versa (i.e. 'fixed').

This notification option is less obtrusive than the other job notifications mentioned above.

**Failed Jobs And First Successful**
Bamboo will send a notification whenever:
- a build of this job fails.
- the job is 'fixed' (that is, the job's latest build is successful and the previous job build failed).

**First Failed Job For Plan**
If multiple jobs fail in a plan, Bamboo will only send a notification for the first failing job detected by the Bamboo system.

This is a less obtrusive notification option that informs about a failing job (and hence, plan) in the shortest possible time.

**Job Error**
Bamboo will send a notification whenever an error occurs in one of the plan's job build processes (i.e. the activities that Bamboo performs to run a job build). This event is not related to failures of the actual build itself (see the Failed Jobs And First Successful and Failed Builds And First Successful events above). For example, a notification will be sent if Bamboo encounters an error when connecting to the repository, or detecting changes.

**Job Hung**
Bamboo will send a notification whenever it determines that one of the plan's job builds has hung, according to the hung job build criteria (read more about configuring your hung job build settings).

Use this notification to ensure that the relevant people are informed when a job build becomes unresponsive.

**Job Queue Timeout**
Bamboo will send a notification whenever one of the plan's job builds has been waiting in the queue for longer than the build queue timeout criteria (read more about configuring your job's Build Queue Timeout settings).

Use this notification to ensure that the relevant people are informed when a job build is stuck in the build queue for too long.

**Job Queued Without Capable Agents**
Bamboo will send a notification whenever one of the plan's job builds is queued and there are no agents capable of building it.

Use this notification to ensure that people are notified when changes to agents adversely affect your job's builds.

**Removing notifications from a plan or job**

You must have the 'Edit' permission for a plan, to add or remove notifications for it.

1. Navigate to the configuration for the desired Plan, as described on Configuring plans.
2. Click the Notifications tab.
3. Click Remove for each of the notifications that you wish to remove.

**Working with Instant Messenger (IM) notifications**

Bamboo can send you notifications about build results for a particular plan. Each plan's recipients are specified by a Bamboo administrator, but you can choose whether you would like to receive your Bamboo notifications via email and/or an instant messenger (IM) service such as Atlassian's Hipchat. See Integrating Bamboo with Hipchat.

As well as receiving IM notifications, you can interact with Bamboo using IM, as described on this page.

On this page:
- Labeling a build result using IM
- Commenting about a build result using IM

Related pages:
- Changing your notification preferences
- Configuring Bamboo to use Instant Messaging
- Getting feedback

**Labeling a build result using IM**

To label a build result using IM:
In your Instant Messenger client, type your comment in the following format:
Entering a build key is optional. If none is specified, Bamboo will look up the last time it corresponded with you and the build that was in context. The context gets updated when you specify a build key in your command, and when Bamboo sends you a notification about a particular build.

Commenting about a build result using IM

To comment on a build result using IM:
In your Instant Messenger client, type your comment in the following format:

```
comment [build key] <comment message>
```

Entering a build key is optional. If none is specified, Bamboo will look up the last time it corresponded with you and the build that was in context. The context gets updated when you specify a build key in your command, and when Bamboo sends you a notification about a particular build.

Screenshot: Interacting with Bamboo using IM

Subscribing to RSS feeds

Bamboo aggregates key information about your builds into RSS feeds. You can subscribe to these feeds using any feed reader.

System level notifications

System level notifications in Bamboo are triggered by a small range of system level events. This means that you don't need to configure these notifications for each plan you are running, as they are applied globally across the Bamboo platform.

Bamboo users can choose whether to receive their notifications via email, IM, both or neither. In general, recipients do not require Bamboo user accounts.

On this page:
- Add system level notifications
- Change system notifications

<td><strong>User</strong> — Enter the username of the appropriate Bamboo user, or click the icon to select from a list of users.</td>
</tr>
<tr>
<td></td>
<td><strong>Hipchat</strong> — Enter the Hipchat API Token and Room Name. See Integrating Bamboo with Hipchat for more information.</td>
</tr>
<tr>
<td></td>
<td><strong>Group</strong> — Enter the name of the appropriate Bamboo group(s).</td>
</tr>
<tr>
<td></td>
<td><strong>Email Address</strong> — You can use email to send notifications to a person who is not a Bamboo user. Type the appropriate email address. Note that:</td>
</tr>
<tr>
<td></td>
<td>• If you specify the email address of an existing Bamboo user, the user will receive notifications even if they have elected not to receive notifications in their user preferences.</td>
</tr>
</tbody>
</table>
IM Address—This is useful if you need to send Instant Messenger (IM) notifications to a person who is not a Bamboo user. Type the appropriate IM address. Note that:

- If you specify a broadcast address (e.g., 'project-x@broadcast.chat.mycompany.com'), Bamboo will not know the context of related IM responses.
- If you specify the IM address of an existing Bamboo user, the user will receive notifications even if they have elected not to receive notifications in their user preferences.

Responsible Users—The Bamboo users who have been assigned as being responsible for a broken build. See Assigning responsibility for build failures.

Committees—The Bamboo users who have committed code to a particular build since build was last checked out by Bamboo.

Watchers—The Bamboo users who have marked this plan as one of their favorites.

5. Click Add to confirm your configuration.

**Change system notifications**

1. Click the icon in the Bamboo header and choose Overview.
2. Select System notifications:
   - Click the pencil symbol in the Actions column to edit the notification.
   - Click the cross symbol in the Actions column to remove the notification.

**Notifications v6.1**

Bamboo can send notifications about build results so that you can find out immediately about the success or failure of your builds.

You can get notifications in different ways:

**Bamboo Wallboard**
Show build results on a dedicated monitor.
See Displaying the wallboard.

**Email (e.g. GMail)**
Get build results in your inbox.
See Configuring notifications.

**Instant messaging (e.g. Hipchat, Google Talk)**
Send notifications to your dev chat room.
See Configuring notifications.

**RSS feeds**
Get aggregated key information about your builds.
See Subscribing to RSS feeds.

See also Changing your notification preferences.

**Notifications v5.14**

Bamboo can send notifications about build results so that you can find out immediately about the success or failure of your builds.

You can get notifications in different ways:

<table>
<thead>
<tr>
<th>Bamboo Wallboard</th>
<th>Show build results on a dedicated monitor.</th>
</tr>
</thead>
<tbody>
<tr>
<td>See Displaying the wallboard.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Email (e.g. GMail)</th>
<th>Get build results in your inbox.</th>
</tr>
</thead>
<tbody>
<tr>
<td>See Configuring notifications.</td>
<td></td>
</tr>
</tbody>
</table>
### Instant messaging (e.g. Hipchat, Google Talk)
Send notifications to your dev chat room.
See Configuring notifications.

### RSS feeds
Get aggregated key information about your builds.
See Subscribing to RSS feeds.

See also Changing your notification preferences.

### Reporting
You are able to get reports about various kinds of activity in Bamboo:

- **Summary statistics for all users**
  A list of summary build statistics for all Bamboo users, showing such things as the number of builds triggered, broken and fixed.
  See Viewing build statistics for all users.

- **Build results for an author**
  Build results summaries for someone who has committed code to projects in Bamboo, including the last 10 builds, the last 10 broken and the last 10 fixed.
  See Viewing build results for an author.

- **Comparison charts for authors**
  Create comparison charts of build activity for selected authors.
  See Generating reports on selected authors.

- **Comparison charts for plans**
  Create comparison charts of build results for selected plans.
  See Generating reports across multiple plans.

- **Clover code-coverage reports**
  See Viewing the Clover code-coverage for a plan.
  See Viewing the Clover code-coverage for a build.

### Viewing build statistics for all users
The build statistics summary gives you an overview of the activity of Bamboo users.

**To view summary statistics for all users:**

1. Click Reports > Authors in the top menu bar
2. Click the List Users tab.

**Related pages:**

**Plan report types**
Some of the standard plan report types are illustrated below.

### Build activity

**Build Activity**

How many builds are triggered in a given time period? This indicates the level of activity for the plan.

<table>
<thead>
<tr>
<th>Chart</th>
<th>Data Table</th>
<th>Builds</th>
</tr>
</thead>
</table>

![Build Activity Chart](chart.png)

**Build duration**
**Build Duration**

The report shows how long your build takes over time. Is it getting slower or faster?

<table>
<thead>
<tr>
<th>Chart</th>
<th>Data Table</th>
<th>Builds</th>
</tr>
</thead>
</table>

**Percentage of Successful Builds**

Comparing success percentages gives you an idea of how stable a plan is compared to one another. 100% means your plan is always rock solid. 0% means something is seriously wrong.

<table>
<thead>
<tr>
<th>Chart</th>
<th>Data Table</th>
<th>Builds</th>
</tr>
</thead>
</table>

*Time to fix*
### Time to Fix

How long does it take on average to fix problems? This provides an indication of how quickly breakages are resolved for the plan.

![Time to Fix Chart](chart)

#### Number of tests

How many tests does your build have? This provides a rough indication of the level of testing over time for the plan.

![Number of Tests Chart](chart)
Number of Build Failures

How many builds are being broken? A high value indicates a relatively unstable plan that tends to be broken often.

**Clover code coverage**

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Viewing the Clover code-coverage for a plan

If you use Atlassian’s Clover and your job specifies a Clover directory (see Enabling the Clover add-on), you will be able to view the Clover code-coverage summary for the plan.

To view the Clover coverage summary for a plan:

1. Locate the plan summary on the Bamboo Dashboard.
2. Click the Clover tab. The Code Coverage Summary information includes:
   - Latest coverage from the most recent build as a percentage and bar representation (aggregated results from all Clover-enabled jobs).
   - A link to detailed HTML reports.
   - Coverage History chart showing changes in percentage Code Coverage over time.
   - Lines of Code History chart showing changes in LOC over time.

Screenshot: the Clover tab for Bamboo 5.6.1 and later.
**Code Coverage Summary**

65% Latest coverage

View latest Clover HTML report from #51 (12:26 AM, Wed, 14 Mar 2012)

**Coverage History**

**Lines of Code History**

Note:
1. Charts are only generated when build results from at least a 2-day span are available. Where shorter time spans are available, the user will receive a warning stating "Insufficient data in range to draw the chart."

2. Where your plan contains multiple jobs with Clover, then Code Coverage and Lines of Code values are aggregated from all these jobs.

3. **Bamboo 5.6.0 and older:** If your plan contains multiple jobs with Clover, the [View latest Clover HTML report](#) link will point to the default job only. In order to see other reports, you must go to the specific job summary, as described in [Viewing the Clover code-coverage for a build](#).

### Viewing the Clover code-coverage for a build

If your organization uses the [Atlassian Clover](#) code-coverage tool, Bamboo can record code-coverage details (i.e. the percentage of code covered by tests) for each build result.

This is only available if the build's plan specifies a Clover directory (for details please refer to the [Enabling the Clover add-on](#)).

Bamboo also provides data on code-coverage trends for a plan over a period of time. For details see the Related pages at right.

**Related pages:**

- Working with build results
- Enabling the Clover add-on
- Generating reports across multiple plans

---

**Clover HTML report for a job**

Where Clover generates an HTML report (created by default in automatic integration), you can examine the report in the build job summary page. To view the report:

1. Go to the plan summary.
2. Select the relevant build number.
3. Select the appropriate job.
4. Click the Clover tab to open the report. If a job produces more than one report, a list is shown and you can switch between them.

**Screen shot: the Clover tab for Bamboo 5.6.1 and later.**

![Clover tab for Bamboo 5.6.1 and later. Only one report is shown. You can access other reports using the Artifacts tab.](#)
Clover statistics report for a job

If your build generates a Clover XML report but not the HTML report, then the Clover Report artifact is not available on the Artifacts tab, however the build job summary page will contain a few code coverage statistics:

1. Go to the plan summary.
2. Select the relevant build number.
3. Select the appropriate job.
4. Click the Clover tab to open the report:

TIP: This usually happens for manual Clover integration. In case you want to see full Clover report, configure it as described on Enabling the Clover add-on page.

References

The content of the Clover HTML report is discussed in detail on the Clover Documentation Home - 4. Understanding Reports page. For completeness, an example Clover Code Coverage HTML report is shown below.
Troubleshooting

The Clover tab shows the directory listing instead of the HTML report

Please check which artifact handler you use. The Amazon S3 Artifact Handler serves files on a one-by-one basis, instead of exposing all files as a static web site. To change this, open Configure plan and on the Miscellaneous tab select the Use custom artifact handler settings check-box. Then select Server-Local Artifact Handler for shared and non-shared artifacts and finally re-run the build. See this bug report: CL OV-1560.

Viewing the Clover code-coverage for a build v5.14

If your organization uses the Atlassian Clover code-coverage tool, Bamboo can record code-coverage details (i.e. the percentage of code covered by tests) for each build result.

This is only available if the build's plan specifies a Clover directory (for details please refer to the Enabling the Clover add-on).

Bamboo also provides data on code-coverage trends for a plan over a period of time. For details see the Related pages at right.

Integrating Bamboo with Atlassian applications

You can integrate Bamboo with the following Atlassian applications:
When Bamboo is integrated with a Jira application, you can:

- See Bamboo development activity in Jira applications. Learn more...
- View detailed Bamboo build result information
- View detailed Bamboo deployment information
- Run a Bamboo build when releasing a Jira Software Server version
- Have Bamboo automatically link a plan branch with an issue
- View the Jira application issues linked to a build result
- View the Bamboo builds that relate to a Jira application project or version

When Bamboo is integrated with Hipchat, you can get notifications from Bamboo for things like:

- when a build passes or fails
- when you are assigned responsibility for a breaking build
- when a build you are responsible for has been fixed
- when a manual stage of a build is ready to be run
- when a deployment starts, and completes

...and many other notification events.

When Bamboo is integrated with Bitbucket, Bamboo will automatically run a build when changes are pushed to the Bitbucket repository, without needing to configure polling.

- Bamboo will automatically update plan branches when a developer pushes a new branch to the repository (or deletes a branch).
- You can click through to Bitbucket to see the commit diff for all files that are part of the changeset.
- Bitbucket commits that are part of a build are displayed in Bamboo.
- Build results are notified to Bitbucket (and displayed for the associated commits and pull requests).

When Bamboo is integrated with Confluence, you can add the following Bamboo gadgets to a Confluence wiki page:

- Bamboo Charts
- Bamboo Plan Summary Chart
- Bamboo Plan Status

When Bamboo is integrated with Fisheye, you can:

- view the code changes that triggered a build
- explore a failed build in Fisheye and jump directly into the changeset that broke the build
- view the history of the changeset to see what the author was trying to fix
- analyze the change using the side-by-side diff view
- open the relevant files in your IDE.

When Bamboo is integrated with Clover, you can:

- View code-coverage details (i.e. the percentage of code covered by tests) for each build result
- View code-coverage trends for a job over a period of time
- View the code-coverage summary for the job.

See The big list of Atlassian gadgets.

**Linking to another application**

Application Links (sometimes called "app links") is a bundled app that allows you to set up links, share information, and provide access to certain resources or functionality across multiple Atlassian products. We recommend using OAuth authentication for application links because of the greater security inherent with that protocol. We no longer recommend the Trusted Applications and Basic authentication types.
Linking Bamboo to other applications allows you to include information from other applications in Bamboo builds. For example, if you link Jira and Bamboo, you can create actionable Jira issues from a Bamboo build, view the Jira issues linked to a build result, and add Bamboo gadgets to a Jira dashboard.

Create an application link

1. Click the icon in the Bamboo header and choose Overview.

2. Choose Application Links in the left navigation bar. You'll see any application links that have already been set up.

3. Enter the URL of the application you want to link to, then click Create new link.
   - If you check The servers have the same set of users... then this link will be configured using OAuth (with impersonation) authentication.
   - If you are not an admin on both servers you won't be able to set up a 2-way (reciprocal) application link. If you want to go ahead and create a 1-way link anyway, clear the I am an administrator on both instances checkbox.

4. Use the wizard to finish configuring the link. If the application you are linking to does not have the Application Links plugin, you must supply additional information to set up a link with OAuth authentication.

When you complete the wizard, the Application Links plugin will create the link between your applications using the most secure authentication method that is supported between the two applications. See the Application Links User Guide for more information.

The new link will appear on the "Configure Application Links" page, where you can:

- Edit the settings of the application link (for example, to change the authentication type of the link) using the Edit icon.
- Specify the default instance if you have multiple links to the same type of application (for example, to multiple Jira servers) using the Make Primary link. See Making a primary link for links to the same application type for more information.

Impersonating and non-impersonating authentication types

OAuth authentication

OAuth authentication redirects a user to log in to the remote application, after which tokens generated on their behalf are used to authorize requests made from the local application. The remote application handling the request uses the access permissions of the account with which the user logged in on that remote application.

Typical scenarios include:

- You are setting up an application link between two applications that do not share the same set of users.
- You want to continue using a link to an application that now allows public sign-on and the link was previously configured with a shared userbase. You can update your application link by changing OAuth (impersonation) to OAuth when editing the application link.

See OAuth security for application links for more information.

OAuth with impersonation

Atlassian OAuth with impersonation makes it easy for your users to benefit from the deep integrations between Atlassian applications:

- they're automatically authenticated on the other application and don't get asked to authorize requests.
- they'll only see the information that they have permission to see.

Impersonating authentication makes requests on behalf of the user who is currently logged in.

Note that Atlassian OAuth with impersonation can only be used for application links between Atlassian applications. Furthermore, it should only be used when the two applications share the same userbase, typically managed with an external directory using LDAP.

A typical scenario is:

- You've set up an application link but your users still have to authenticate regularly. This can occur when the application link has been configured to not share the same userbase. If those applications do share the same userbase, you can update your application link by selecting OAuth (impersonation) when editing the application link.

See OAuth security for application links for more information.

Troubleshooting

Having trouble integrating your Atlassian products with application links?
We've developed a guide to troubleshooting application links, to help you out. Take a look at it if you need a hand getting around any errors or roadblocks with setting up application links.
Integrating Bamboo with Jira applications

Integrating Bamboo with Atlassian’s Jira applications combines Bamboo’s continuous integration capabilities with your issue tracker to give you a unified view of your software development project.

Configuring Bamboo and Jira applications to work together simply requires you to set up an application link (two-way) between a Jira application and Bamboo.

Note that application links have nothing to do with using a Jira application as a user directory for Bamboo; these 2 configurations can exist separately. See also Linking to another application.

On this page:
- Benefits
- Requirements
- Configuration
- Notes

Benefits

See Viewing Bamboo activity in a Jira application for a full description of the benefits of integrating Jira applications with Bamboo.

Briefly, these are:

<table>
<thead>
<tr>
<th>Integration feature</th>
<th>Description</th>
<th>Compatibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Development panel</td>
<td>See Bamboo development activity</td>
<td>6.2 + 5.4 +</td>
</tr>
<tr>
<td>Build result dialog</td>
<td>View detailed Bamboo build result information</td>
<td>6.2 + 5.4 +</td>
</tr>
<tr>
<td>Deployment dialog</td>
<td>View detailed Bamboo deployment information</td>
<td>6.2 + 5.4 +</td>
</tr>
<tr>
<td>Run Bamboo builds</td>
<td>Run a Bamboo build when releasing a Jira application version</td>
<td>4.4 + 3.0 +</td>
</tr>
<tr>
<td>Linked plan branches</td>
<td>Have Bamboo automatically link a plan branch with an issue</td>
<td>4.4 + 3.0 +</td>
</tr>
<tr>
<td>Jira issues view</td>
<td>View the issues linked to a build result</td>
<td>4.4 + 3.0 +</td>
</tr>
<tr>
<td>Jira Projects</td>
<td>View the Bamboo builds that relate to a Jira application project or version</td>
<td>4.4 + 3.0 +</td>
</tr>
</tbody>
</table>

If you are using an earlier version of Bamboo and/or a Jira application, you can also download an older version of the Jira Bamboo plugin from the Atlassian Plugin Exchange. However, we strongly advise you to upgrade Jira to version 6.2 or later and Bamboo to version 5.4 or later, to get the most out of Bamboo - Jira applications integration.

Requirements

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jira 6.2+</td>
<td>Earlier versions of Jira do not support the Development panel feature.</td>
</tr>
<tr>
<td>Bamboo 5.4+</td>
<td></td>
</tr>
<tr>
<td>Jira/Bamboo Applink</td>
<td>See below for details about application links.</td>
</tr>
<tr>
<td>Permissions</td>
<td>Users will require the ‘View development tools’ permission in Jira applications.</td>
</tr>
<tr>
<td>Issue key</td>
<td>The issue key must be included in the commit message, and must use the default issue key format.</td>
</tr>
</tbody>
</table>

Configuration

Integration of Bamboo and a Jira application requires an application link between them. The application link needs both 2-legged (2LO) and 3-legged OAuth (3LO) authentication:

- 2LO is required for information from Bamboo to be included in the summaries in the Development panel.
- 3LO checks that a user has authenticated with Bamboo before they get to see the information in any of the details dialogs. Users...
who can see summarized data in the Development panel may not have permission to see all the information that contributed to those summaries and which is visible in the details dialogs. That is, the details dialogs respect the access permissions that users have in the connected Bamboo server.

When you create a new link between a Jira application and Bamboo, both 2-legged (2LO) and 3-legged OAuth (3LO) are enabled by default.

- You will need to set up a two-way link. That is, select the Create a link back to this server option when adding the application link.

An existing application link between Jira and Bamboo may need to have 2LO authentication explicitly enabled.

- Click here to see how to enable 2-legged OAuth...

An existing application link between a Jira application and Bamboo (that perhaps used Trusted Apps authentication) needs to have 2-legged authentication (2LO) enabled for both outgoing and incoming authentication, so that information from the application can be included in the Development panel summaries.

When updating an older application link to use OAuth, 3-legged authentication is applied by default, but you need to explicitly enable 2LO. Enable 2-legged authentication for the application link from within Jira as follows:

1. Go to the Jira admin area and click Applications > Application Links.
2. Click Edit for the app link with the other application.
3. For both Outgoing Authentication and Incoming Authentication:
   a. Click OAuth
   b. Check Allow 2-legged OAuth.
   c. Click Update.

The application link update process will involve logging you into the other application for a short time to configure that end of the link, before returning you to Jira application.

Note that:

- Application links must have Trusted Applications and Basic Access authentication disabled. The Development panel in Jira only supports OAuth authentication.
- You will need to configure 2-legged OAuth enabled for both incoming and outgoing authentication in both Jira application and Bamboo for your application link.
- See Configuring authentication for an application link for more information.
- If you are running Bamboo behind a proxy, you may need to configure the AJP connector.

Notes

Known issues

- Jira applications and Bamboo cannot run in the same Tomcat instance due to a known issue with the Bamboo plugin for Jira applications (see JRA-19662).
- When integrating Bamboo with a Jira application, you should not change the Jira application project key format from the default, as Bamboo only supports the default project key format.

If you need further help, please raise a support request in our support system, in the Bamboo project. You may also want to view articles in the Bamboo Knowledge Base and browse our forums.

Viewing linked Jira application issues

If your organization uses Atlassian's Jira application and your administrator has integrated Bamboo with a Jira application, you will be able to view the issues that have been linked to a build. This provides an easy way to jump to relevant issues in the Jira application to see details about what the code is intended to achieve.

Linked issues can be viewed on:

- the Issues tab of the Plan Summary page, for all issues linked to the plan
- the Build Result Summary page, for just 2 of the issues linked to a build
- the Issues tab of the Build Result Summary page, for issues linked to a build.

Issue links can be created automatically by Bamboo when you specify an issue key in your build comments, labels or commit messages, or they can be added manually.

On this page:

Viewing the Jira issues linked to a plan's builds

To view the issues linked to all builds for a plan:
1. Navigate to the desired plan, as described on Configuring plans.
2. Click the Issues tab. A list of all of the issues linked to builds for the plan are displayed, sorted by build date. You can constrain the list using the build filter (e.g. 'Showing last 25 builds') next to the tabs.
   - Click the issue key to view the issue in the Jira application.
   - Click the N related builds link (where N is a number of builds) to view the builds linked to that issue on the Builds tab in the Jira application.

```
<table>
<thead>
<tr>
<th>JIRA Issues</th>
</tr>
</thead>
<tbody>
<tr>
<td>This page lists the JIRA issues that have been linked to builds related to this plan, ordered by last built. This includes issues specified in commit messages, labels or comments for builds, as well as issues manually linked to builds.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>JIRA Issues (15 issues)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>------</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>

Linking Jira application issues to a build

If your organization uses Atlassian’s Jira and your administrator has integrated Bamboo with Jira:

- Bamboo will automatically link Jira issues to builds.
- You can manually link an issue to a build.

Automatically linking issues to a build

Bamboo will automatically link an issue to a build if you specify a Jira issue key in a Bamboo build comment or label, or in a code commit message.

The issue key must be of the default Jira issue key format (that is, two or more uppercase letters \([A-Z]\) \([A-Z]\) +, followed by a hyphen and the issue number, for example BAM-123).

**On this page:**

- Automatically linking issues to a build
- Manually linking issues to a build
Manually linking issues to a build

If an issue has not been linked automatically to your build, you can manually create a link from that issue to your build.

To manually link a Jira Issue to a build result:

1. Go to the plan in Bamboo.
2. Click on the build number for a build result.
3. Click the Issues tab in the 'Build Result Summary'. All of the Jira issues linked to your build will be listed.
4. Click Add linked issue.
5. Enter the Jira issue key of the issue you want to link to this build. Please note, the issue key must be of the default Jira issue key format (that is, two or more uppercase letters ([A-Z][A-Z]+), followed by a hyphen and the issue number, for example BAM-123).
6. Click Save.

Manually linking issues to a build

If an issue has not been linked automatically to your build, you can manually create a link from that issue to your build.

To manually link a Jira Issue to a build result:

1. Go to the plan in Bamboo.
2. Click on the build number for a build result.
3. Click the Issues tab in the 'Build Result Summary'. All of the Jira issues linked to your build will be listed.
4. Click Add linked issue.
5. Enter the Jira issue key of the issue you want to link to this build. Please note, the issue key must be of the default Jira issue key format (that is, two or more uppercase letters ([A-Z][A-Z]+), followed by a hyphen and the issue number, for example BAM-123).
6. Click Save.
1. If your organization uses Atlassian's Jira and your administrator has integrated Bamboo with Jira:
   - Bamboo will automatically link Jira issues to builds.
   - You can manually link an issue to a build.

2. **Automatically linking issues to a build**
   Bamboo will automatically link an issue to a build if you specify a Jira issue key in a Bamboo build comment or label, or in a code commit message.
   The issue key must be of the default Jira issue key format (that is, two or more uppercase letters ([A-Z] [A-Z]+), followed by a hyphen and the issue number, for example BAM-123).

3. **Manually linking issues to a build**
   If an issue has not been linked automatically to your build, you can manually create a link from that issue to your build.

   **To manually link a Jira Issue to a build result:**
   1. Go to the plan in Bamboo.
   2. Click on the build number for a build result.
   3. Click the Issues tab in the 'Build Result Summary'. All of the Jira issues linked to your build will be listed.
   4. Click Add linked issue.
   5. Enter the Jira issue key of the issue you want to link to this build. Please note, the issue key must be of the default Jira issue key format (that is, two or more uppercase letters ([A-Z] [A-Z]+), followed by a hyphen and the issue number, for example BAM-123).
   6. Click Save.

4. **Creating Jira application issues from a build**
   When Bamboo is integrated with Jira Software Server, you can create new issues right from your Bamboo build result. You can easily:
When you create an issue from Bamboo, the issue in Jira Software links back to the build result it was created from.

A link to the new issue is displayed in the 'Jira Issues' section of the Build Result Summary, and on the Issues tab, in Bamboo.

To take advantage of Jira Software issue creation in Bamboo:

- You require Jira 5.0, or higher.
- There must be an application link already set up between Jira Software and Bamboo.
- Your Jira application administrator needs to have enabled fully reciprocal issue linking in Jira Software Server.

**Related pages:**
- Linking Jira application issues to a build

**To create a new Jira Software issue from a Bamboo build:**

1. On the Build Result Summary, choose Actions > Create Issue.
2. Complete the form.
3. Click Create.

Creating Jira application issues from a build v5.14

When Bamboo is integrated with Jira Software Server, you can create new issues right from your Bamboo build result. You can easily:

- Capture critical infrastructure failures that are keeping your build from passing.
- Request that a successful build be deployed to the next environment.
- Create a searchable knowledge base of failure causes and solutions.
- Log time spent on build failures and use Jira Software dashboard gadgets to discover trends over time.

When you create an issue from Bamboo, the issue in Jira Software links back to the build result it was created from.

A link to the new issue is displayed in the 'Jira Issues' section of the Build Result Summary, and on the Issues tab, in Bamboo.

To take advantage of Jira Software issue creation in Bamboo:

- You require Jira 5.0, or higher.
- There must be an application link already set up between Jira Software and Bamboo.
- Your Jira application administrator needs to have enabled fully reciprocal issue linking in Jira Software Server.

**Related pages:**
- Linking Jira application issues to a build

**To create a new Jira Software issue from a Bamboo build:**

1. On the Build Result Summary, choose Actions > Create Issue.
2. Complete the form.
3. Click Create.

Creating Jira application issues from a build v6.5

When Bamboo is integrated with Jira Software Server, you can create new issues right from your Bamboo build result. You can easily:

- Capture critical infrastructure failures that are keeping your build from passing.
- Request that a successful build be deployed to the next environment.
- Create a searchable knowledge base of failure causes and solutions.
- Log time spent on build failures and use Jira Software dashboard gadgets to discover trends over time.

When you create an issue from Bamboo, the issue in Jira Software links back to the build result it was created from.

A link to the new issue is displayed in the 'Jira Issues' section of the Build Result Summary, and on the Issues tab, in Bamboo.

To take advantage of Jira Software issue creation in Bamboo:

- You require Jira 5.0, or higher.
- There must be an application link already set up between Jira Software and Bamboo.
- Your Jira application administrator needs to have enabled fully reciprocal issue linking in Jira Software Server.

3. Click Create.
Viewing Bamboo activity in Jira applications

**Overview**

When Bamboo is integrated with Jira applications, Bamboo can pass important development information back to a Jira application. Currently Bamboo can pass Jira application information relating to:

- Build results
- Deployment statuses

With supported versions of Bamboo and a Jira application, this information is collated within the Development Panel. This panel summarizes the status of all work related to an issue, and can assist in identifying where an issue's build is failing, and where it has been deployed.

**Example**

- If you are working on issue BAM-12443, then you can see if it has been deployed to a development server yet
- A QA can also check to see if it's on their QA server and ready for testing
- A manager can see if a bug has made it to production.

Linking Jira applications and Bamboo has the benefit of improved information exchange during your development process.

See Integrating Bamboo with Jira applications for information about permissions and configuration.

**Related pages:**

- Linking issues to a build

**On this page:**

- Overview
- The development panel
- Viewing build result information
- Viewing deployment information

The development panel

The Development panel provides an 'at-a-glance' development information resource, and is visible to anyone with the "View development tools" project permission. The panel replaces the Builds tab and Issue deployment panel, and summarizes an assortment of development data passed to Jira applications from Bamboo and other Atlassian products. Examples include:

- Feature branch creation from Jira applications
- Viewing repository branches in Bitbucket Cloud or Bitbucket Server
- Viewing commits and pull requests to Git repositories managed by Bitbucket Cloud or Bitbucket Server
Viewing build result information

The Development panel shows the status of the latest Bamboo builds related to your linked issue. Using simple status icons builds are reported as:

- all the different builds (for example, unit tests, functional tests, deploy to staging) succeeded
- at least one run failed for any build by any linked instance of Bamboo.

A build is automatically linked to an issue if one of the build's commits includes the issue key in its commit message. The issue key must be included in the commit to activate this feature.

Click the associated **builds** link to see additional build details including the name of the plan branch and how many tests passed or failed:

<table>
<thead>
<tr>
<th>Plan</th>
<th>Latest build</th>
<th>Result</th>
<th>Completed</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI JIRA DevStatus Plugin Webdriver Qunit Func Tests</td>
<td>✔️ #15</td>
<td>1068 tests passed in 32 minutes</td>
<td>10/Dec/13 2:20 AM</td>
</tr>
<tr>
<td>FUSE-38 _create_deployments_renderer</td>
<td>DISABLED</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Viewing deployment information

A deployment to an environment, such as Production or testing, is linked to an issue if a commit associated with the deploy contains the issue key in its commit message. The Development panel details the environments that associated Bamboo builds have been deployed to.

The issue key must be included in the commit to activate this feature.

Click the **Deployed** link to see deployment details including the deployment status, release date, and click through to view a particular deployment:
Overview

When Bamboo is integrated with Jira applications, Bamboo can pass important development information back to a Jira application. Currently Bamboo can pass Jira application information relating to:

- Build results
- Deployment statuses

With supported versions of Bamboo and a Jira application, this information is collated within the Development Panel. This panel summarizes the status of all work related to an issue, and can assist in identifying where an issue's build is failing, and where it has been deployed.

Example

- If you are working on issue BAM-12443, then you can see if it has been deployed to a development server yet
- A QA can also check to see if it's on their QA server and ready for testing
- A manager can see if a bug has made it to production.

Click the Deployed link to see deployment details including the deployment status, release date, and click through to view a particular deployment:
Integrating builds with your issues workflow

You can configure a workflow in Jira applications, so that the workflow is actioned when a build completes successfully. For example, you can configure a workflow to automatically progress an issue from 'Building' to 'Resolved' status. You could also configure the same workflow to progress an issue from 'Building' to 'Build Broken' status if a build related to that issue fails. A build is related to an issue if the build involves a commit that had the issue key added to commit message.

On this page:
- Understanding the 'Builds Workflow'
- Using the 'Builds Workflow' in your projects
- Modifying the 'Builds Workflow'
- Integrating build transitions into your custom workflow

A Builds Workflow exists in Jira applications and it incorporates the common statuses and transitions (see the Understanding the 'Builds Workflow' section below).

- If you are new to Jira applications and Bamboo, we recommend that you use the 'Builds Workflow' as modifying an existing workflow is not a trivial task.
- If you have an existing workflow that you would like to modify to include build statuses and transitions, we recommend that you take a copy of the 'Builds Workflow' and modify it.
- If you want to integrate Bamboo transitions into your existing workflow, you can edit your workflow to add the transitions. We recommend that you avoid doing unless you have a good understanding of the workflows.

Understanding the 'Builds Workflow'

Diagram: The default Builds Workflow

<table>
<thead>
<tr>
<th>#</th>
<th>Transition</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Start Progress</td>
</tr>
<tr>
<td>2</td>
<td>Stop Progress</td>
</tr>
<tr>
<td>3</td>
<td>Resolve Issue</td>
</tr>
<tr>
<td>4</td>
<td>Close Issue</td>
</tr>
<tr>
<td>5</td>
<td>Reopen Issue</td>
</tr>
<tr>
<td>6</td>
<td>Wait for Build</td>
</tr>
<tr>
<td>7</td>
<td>Build Passed</td>
</tr>
<tr>
<td>8</td>
<td>Build Failed</td>
</tr>
</tbody>
</table>
The 'Wait for Build', 'Build Passed' and 'Build Failed' transitions are Bamboo-specific transitions:

- **'Wait for Build'** — This transition will be triggered when code is committed for this issue (and a build started) using the `#wait` or `wait` commit command. Note, you must manually enter the commit command in your commit message to trigger the transition, as described in Using Smart Commits.
- **'Build Passed'** — This transition will be automatically triggered when a build for this issue passes.
- **'Build Failed'** — This transition will be automatically triggered when a build for this issue fails.

### Using the 'Builds Workflow' in your projects

The following instructions describe how to create a workflow scheme that uses the 'Builds Workflow', and then associate the workflow scheme with a project. If you want to add the 'Builds Workflow' to an existing workflow scheme, ignore steps 4-6 below and assign the workflow to your existing workflow scheme instead.

#### Procedure

1. **Creating a workflow scheme that uses the Builds Workflow**
   1. Log in as an admin for your site.
   2. In the administration console of a Jira application, go to Workflows > Workflow Schemes. The 'Workflow Schemes' page will display.
   3. Click Add workflow scheme.
   4. Enter a Name and Description for your workflow scheme and click Add. Your workflow scheme will be created and you will see the page for editing the workflow.
   5. Click Assign a workflow.
   6. In the Issue Type dropdown, select the issue types that you want the 'Builds Workflow' to apply to. In the Workflow drop-down list, select Builds Workflow. Click Add.

2. **Associating the workflow scheme with your project**
   1. Log in as a user with the 'Jira application Administrators' global permission.
   2. Go to the 'Project Summary' page. Keyboard shortcut: `g + g +` start typing 'projects'.
   3. Click Workflows on the left of the 'Project Summary' page (you can also click the More link in the 'Workflows' section in the middle of the screen). The 'Workflows' page is displayed, indicating the current workflow scheme used by the project.
   4. Click Switch Scheme to display the 'Associate Workflow Scheme to Project' page.
   5. Select the relevant workflow scheme from the Scheme list and click Associate to begin the migration process. The 'Builds Workflow' will be associated with your project via your workflow scheme.
   6. Click Acknowledge to finish the process.
   7. Select the project you wish to use the 'Builds Workflow' with.

Issues (of the issue types specified in your workflow scheme) will now use the 'Builds Workflow'. If you add the issue key of an issue to the commit message when committing, the issue will be automatically transitioned along the workflow when the build starts/succeeds/fails.

### Modifying the 'Builds Workflow'

You cannot modify the 'Builds Workflow' itself because it is non-editable. However, you can copy it and edit the copy if the original 'Builds Workflow' is non-editable.
Workflow’ doesn’t suit the needs of your project. You can then activate the new (copied) workflow by adding it to a workflow scheme and then associating that scheme with your projects.

**Copying and editing the ‘Builds Workflow’**

1. Log in as an admin for your site.
2. In the Jira administration console of a Jira application, go to Schemes > Workflow Schemes. The ‘Workflow Schemes’ page will display.
3. Click View all workflows.
4. Locate the ‘Builds Workflow’ and click Copy in the ‘Operations’ column.
5. Enter a Name and Description for the new (copied) workflow scheme and click Copy. The new workflow will be created and displayed on the ‘View Workflows’ page.
6. You can now edit and activate your new workflow as needed. See Configuring Workflow and Activating workflow in the Jira Server Administration documentation for more information on how to do this.

**Integrating build transitions into your custom workflow**

If modifying a copy of the ‘Builds Workflow’ is not feasible for your projects, it is possible to manually modify your existing workflow to include the Bamboo transitions. It is recommended that you avoid doing so unless you have a good understanding of the workflows.

To integrate build transitions into your existing custom workflow, edit your workflow and configure appropriate issue statuses and issue transitions as described below.

**Configuring your issue statuses**

We recommend that you set up issue statuses for your workflow to indicate when a build related to an issue is building or the build is broken (e.g. ‘Building’, ‘Build Broken’). There is no technical restriction preventing you from incorporating Bamboo-specific build transitions into a workflow without these intermediate states, however, in practice it will cause problems.

For example, a developer may work on an issue, and commit several times over the course of a few days for that issue. Even if earlier commits cause the build to pass, the developer may not have finished working on the issue and will need to commit more code without successful builds resolving the issue. Hence, an intermediate state (e.g. ‘Building’) is required which a developer will only transition the issue into (i.e. using the #build commit command), if they want the issue to be resolved from that particular build.

**Configuring your issue transitions**

Automatic issue transitioning via builds is controlled by both commit commands and Bamboo-specific transition properties in Jira applications, as described below:

- **Commit Command** — Commit commands are mapped to transition names. Hence, if you add the ‘Waiting for Build’ transition to your workflow, your users will be able to automatically trigger the transition by using the #wait or #wait-for-build commit command in their commit messages.

- **Bamboo-specific transition properties** — The Bamboo-specific transition properties on the transitions that you want to be triggered when a Bamboo build passes or fails. The following properties are supported:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>build.passed.transition</td>
<td>anything</td>
<td>A transition with this property will be triggered when a build for this issue passes, and the transition is available to the issue in its current state.</td>
</tr>
<tr>
<td>build.failed.transition</td>
<td>anything</td>
<td>A transition with this property will be triggered when a build for this issue fails, and the transition is available to the issue in its current state.</td>
</tr>
<tr>
<td>build.passed.resolution</td>
<td>any valid resolution, e.g. 'Fixed'</td>
<td>The issue resolution will be set as specified by this property, if the transition with this property is triggered by a build.</td>
</tr>
</tbody>
</table>

Please note, you cannot set up common transition properties in Jira applications. You will need to manually re-enter the transition property on each transition that you want it added to.

**Integrating builds with your issues workflow v5.14**

You can configure a workflow in Jira applications, so that the workflow is actioned when a build completes successfully. For example, you can configure a workflow to automatically progress an issue from ‘Building’ to ‘Resolved’ status. You could also configure the same workflow to progress an issue from ‘Building’ to ‘Build Broken’ status if a build related to that issue fails. A build is related to an issue if the build involves a commit that had the issue key added to commit message.

5. Enter a Name and Description for the new (copied) workflow scheme and click Copy. The new workflow will be created and displayed on the 'View Workflows' page.
6. You can now edit and activate your new workflow as needed. See Configuring Workflow and Activating workflow in the Jira Server Administration documentation for more information on how to do this.

Integrating build transitions into your custom workflow

If modifying a copy of the 'Builds Workflow' is not feasible for your projects, it is possible to manually modify your existing workflow to include the Bamboo transitions. It is recommended that you avoid doing so unless you have a good understanding of the workflows.

To integrate build transitions into your existing custom workflow, edit your workflow and configure appropriate issue statuses and issue transitions as described below.

Configuring your issue statuses

We recommend that you set up issue statuses for your workflow to indicate when a build related to an issue is building or the build is broken (e.g. 'Building', 'Build Broken'). There is no technical restriction preventing you from incorporating Bamboo-specific build transitions into a workflow without these intermediate states, however, in practice it will cause problems.

For example, a developer may work on an issue, and commit several times over the course of a few days for that issue. Even if earlier commits cause the build to pass, the developer may not have finished working on the issue and will need to commit more code without successful builds resolving the issue. Hence, an intermediate state (e.g. 'Building') is required which a developer will only transition the issue into (i.e. using the #build commit command), if they want the issue to be resolved from that particular build.

Configuring your issue transitions

Automatic issue transitioning via builds is controlled by both commit commands and Bamboo-specific transition properties in Jira applications, as described below:

- **Commit Command** — Commit commands are mapped to transition names. Hence, if you add the 'Waiting for Build' transition to your workflow, your users will be able to automatically trigger the transition by using the #wait or #wait-for-build commit command in their commit messages.
- **Bamboo-specific transition properties** — The Bamboo-specific transition properties on the transitions that you want to be triggered when a Bamboo build passes or fails. The following properties are supported:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>build.passed.transition</td>
<td>anything</td>
<td>A transition with this property will be triggered when a build for this issue passes, and the transition is available to the issue in its current state.</td>
</tr>
<tr>
<td>build.failed.transition</td>
<td>anything</td>
<td>A transition with this property will be triggered when a build for this issue fails, and the transition is available to the issue in its current state.</td>
</tr>
<tr>
<td>build.passed.resolution</td>
<td>any valid resolution, e.g. 'Fixed'</td>
<td>The issue resolution will be set as specified by this property, if the transition with this property is triggered by a build.</td>
</tr>
</tbody>
</table>

Please note, you cannot set up common transition properties in Jira applications. You will need to manually re-enter the transition property on each transition that you want it added to.

Integrating Bamboo with Jira applications v6.0

Integrating Bamboo with Atlassian's Jira applications combines Bamboo's continuous integration capabilities with your issue tracker to give you a unified view of your software development project.

Configuring Bamboo and Jira applications to work together simply requires you to set up an application link (two-way) between a Jira application and Bamboo.

Note that application links have nothing to do with using a Jira application as a user directory for Bamboo; these 2 configurations can exist separately. See also Linking to another application.

On this page:
- Benefits
- Requirements
- Configuration
- Notes

Benefits

See Viewing Bamboo activity in a Jira application for a full description of the benefits of integrating Jira applications with Bamboo.

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Briefly, these are:

<table>
<thead>
<tr>
<th>Integration feature</th>
<th>Description</th>
<th>Compatibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jira 7.7 release notes</td>
<td>See Jira 7.7 release notes</td>
<td>7.7 +</td>
</tr>
<tr>
<td>Bamboo 5.4 +</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Development info in issue search</td>
<td>Run a Bamboo build when releasing a Jira application version</td>
<td>4.4 +</td>
</tr>
<tr>
<td>Development panel</td>
<td>See Bamboo development activity</td>
<td>6.2 +</td>
</tr>
<tr>
<td>Build result dialog</td>
<td>View detailed Bamboo build result information</td>
<td>6.2 +</td>
</tr>
<tr>
<td>Deployment dialog</td>
<td>View detailed Bamboo deployment information</td>
<td>6.2 +</td>
</tr>
<tr>
<td>Jira issues view</td>
<td>View the issues linked to a build result</td>
<td>4.4 +</td>
</tr>
<tr>
<td>Jira Projects</td>
<td>View the Bamboo builds that relate to a Jira application project or version</td>
<td>4.4 +</td>
</tr>
</tbody>
</table>

If you are using an earlier version of Bamboo and/or a Jira application, you can also download an older version of the Jira Bamboo plugin from the Atlassian Plugin Exchange. However, we strongly advise you to upgrade Jira to version 6.2 or later and Bamboo to version 5.4 or later, to get the most out of Bamboo - Jira applications integration.

Requirements

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jira 6.2+</td>
<td>Earlier versions of Jira do not support the Development panel feature.</td>
</tr>
<tr>
<td>Bamboo 5.4+</td>
<td></td>
</tr>
<tr>
<td>Jira/Bamboo Applink</td>
<td>See below for details about application links.</td>
</tr>
<tr>
<td>Permissions</td>
<td>Users will require the 'View development tools' permission in Jira applications.</td>
</tr>
<tr>
<td>Issue key</td>
<td>The issue key must be included in the commit message, and must use the default issue key format.</td>
</tr>
</tbody>
</table>

Configuration

Integration of Bamboo and a Jira application requires an application link between them. The application link needs both 2-legged (2LO) and 3-legged OAuth (3LO) authentication:

- 2LO is required for information from Bamboo to be included in the summaries in the Development panel.
- 3LO checks that a user has authenticated with Bamboo before they get to see the information in any of the details dialogs. Users who can see summarized data in the Development panel may not have permission to see all the information that contributed to those summaries and which is visible in the details dialogs. That is, the details dialogs respect the access permissions that users have in the connected Bamboo server.

When you create a new link between a Jira application and Bamboo, both 2-legged (2LO) and 3-legged OAuth (3LO) are enabled by default.

- You will need to set up a two-way link. That is, select the Create a link back to this server option when adding the application link.

An existing application link between Jira and Bamboo may need to have 2LO authentication explicitly enabled.

- Click here to see how to enable 2-legged OAuth...
- An existing application link between a Jira application and Bamboo (that perhaps used Trusted Apps authentication) needs to have 2-legged authentication (2LO) enabled for both outgoing and incoming authentication, so that information from the application can be included in the Development panel summaries.

When updating an older application link to use OAuth, 3-legged authentication is applied by default, but you need to explicitly enable 2LO. Enable 2-legged authentication for the application link from within Jira as follows:

1. Go to the Jira admin area and click Applications > Application Links.
2. Click Edit for the app link with the other application.
3. For both Outgoing Authentication and Incoming Authentication:
   a. Click OAuth
b. Check Allow 2-legged OAuth.

c. Click Update.

The application link update process will involve logging you into the other application for a short time to configure that end of the link, before returning you to Jira application.

Note that:

- Application links must have Trusted Applications and Basic Access authentication disabled. The Development panel in Jira only supports OAuth authentication.
- You will need to configure 2-legged OAuth enabled for both incoming and outgoing authentication in both Jira application and Bamboo for your application link.
- See Configuring authentication for an application link for more information.
- If you are running Bamboo behind a proxy, you may need to configure the AJP connector.

**Notes**

**Known issues**

- Jira applications and Bamboo cannot run in the same Tomcat instance due to a known issue with the Bamboo plugin for Jira applications (see JIRA-19662).
- When integrating Bamboo with a Jira application, you should not change the Jira application project key format from the default, as Bamboo only supports the default project key format.

If you need further help, please raise a support request in our support system, in the Bamboo project. You may also want to view articles in the Bamboo Knowledge Base and browse our forums.

### Integrating Bamboo with Jira applications v5.14

Integrating Bamboo with Atlassian's Jira applications combines Bamboo's continuous integration capabilities with your issue tracker to give you a unified view of your software development project.

Configuring Bamboo and Jira applications to work together simply requires you to set up an application link (two-way) between a Jira application and Bamboo.

Note that application links have nothing to do with using a Jira application as a user directory for Bamboo; these 2 configurations can exist separately. See also Linking to another application.

</tbody>
</table>

Configuration

Integration of Bamboo and a Jira application requires an application link between them. The application link needs both 2-legged (2LO) and 3-legged OAuth (3LO) authentication:

- 2LO is required for information from Bamboo to be included in the summaries in the Development panel.
- 3LO checks that a user has authenticated with Bamboo before they get to see the information in any of the details dialogs. Users who can see summarized data in the Development panel may not have permission to see all the information that contributed to those summaries and which is visible in the details dialogs. That is, the details dialogs respect the access permissions that users have in the connected Bamboo server.

When you create a new link between a Jira application and Bamboo, both 2-legged (2LO) and 3-legged OAuth (3LO) are enabled by default.

- You will need to set up a two-way link. That is, select the Create a link back to this server option when adding the application link.

An existing application link between Jira and Bamboo may need to have 2LO authentication explicitly enabled.

- Click here to see how to enable 2-legged OAuth...

An existing application link between a Jira application and Bamboo (that perhaps used Trusted Apps authentication) needs to have 2-legged authentication (2LO) enabled for both outgoing and incoming authentication, so that information from the application can be included in the Development panel summaries.

When updating an older application link to use OAuth, 3-legged authentication is applied by default, but you need to explicitly enable 2LO. Enable 2-legged authentication for the application link from within Jira as follows:

1. Go to the Jira admin area and click Applications > Application Links.
2. Click Edit for the app link with the other application.
3. For both Outgoing Authentication and Incoming Authentication:
   a. Click OAuth
   b. Check Allow 2-legged OAuth.
   c. Click Update.

The application link update process will involve logging you into the other application for a short time to configure that end of the link, before returning you to Jira application.

Note that:

- Application links must have Trusted Applications and Basic Access authentication disabled. The Development panel in Jira only supports OAuth authentication.
- You will need to configure 2-legged OAuth enabled for both incoming and outgoing authentication in both Jira application and Bamboo for your application link.
- See Configuring authentication for an application link for more information.
- If you are running Bamboo behind a proxy, you may need to configure the AJP connector.

Notes

Known issues

- Jira applications and Bamboo cannot run in the same Tomcat instance due to a known issue with the Bamboo plugin for Jira applications (see JIRA-19662).
- When integrating Bamboo with a Jira application, you should not change the Jira application project key format from the default, as Bamboo only supports the default project key format.

If you need further help, please raise a support request in our support system, in the Bamboo project. You may also want to view articles in the Bamboo Knowledge Base and browse our forums.

Integrating Bamboo with Hipchat

Bamboo can send notifications about build results to Hipchat so you can find out immediately about the success or failure of your builds.
You get Bamboo notifications in your chat room for events such as:

- when a build passes or fails
- when you are assigned responsibility for a breaking build
- when a build you are responsible for has been fixed
- when a manual stage of a build is ready to be run
- when a deployment starts, and completes

...and many other notification events.

You can configure Bamboo to send notifications to rooms whether they're hosted by Atlassian on hipchat.com, or by your own organization's Hipchat Server instance:

- Configure Bamboo plans to send notifications to a room in hipchat.com
- Configure Bamboo plans to send notifications to your Hipchat server

Configure Bamboo plans to send notifications to a room in hipchat.com

To get notifications in rooms hosted by Atlassian on hipchat.com:

1. Sign up for a Hipchat account.
2. Set up plan notifications in Bamboo that use the 'Hipchat' Recipient type.

Note that Bamboo does not yet support using Hipchat as a global IM server. Hipchat can only be used in the plan notifications area as shown here:

Configure Bamboo plans to send notifications to your Hipchat server

You can get Bamboo plan notifications in rooms hosted by your own organization's Hipchat Server instance:

1. Install the Hipchat Server's SSL root or primary certificate in $JAVA_HOME/jre/lib/security/cacerts keystore on the Bamboo host machine and restart Bamboo.  
   Applicable if you're using a self-signed or internally signed SSL certificate.
2. Specify the hipchat.api.url system property that is used when Bamboo is starting, by adding `-Dhipchat.api.url=<my_hipchat_url>` to your JVM arguments as per Configuring system properties.
3. Set up plan notifications in Bamboo that use the 'Hipchat' Recipient type.
4. Use a Hipchat V1 token in the API Token field.
5. Choose your Room Name or ID.
6. Check the Notify flag to send pop-up notification to the room.

For more information about setting up your own Hipchat server, see System Requirements for Hipchat Server.
Integrating Bamboo with Hipchat v5.14

Bamboo can send notifications about build results to Hipchat so you can find out immediately about the success or failure of your builds.

You get Bamboo notifications in your chat room for events such as:

- when a build passes or fails
- when you are assigned responsibility for a breaking build
- when a build you are responsible for has been fixed
- when a manual stage of a build is ready to be run
- when a deployment starts, and completes

...and many other notification events.

You can configure Bamboo to send notifications to rooms whether they're hosted by Atlassian on hipchat.com, or by your own organization's Hipchat Server instance:

- Configure Bamboo plans to send notifications to a room in hipchat.com
- Configure Bamboo plans to send notifications to your Hipchat server

Configure Bamboo plans to send notifications to a room in hipchat.com

To get notifications in rooms hosted by Atlassian on hipchat.com:

1. Sign up for a Hipchat account.
2. Set up plan notifications in Bamboo that use the 'Hipchat' Recipient type.

Note that Bamboo does not yet support using Hipchat as a global IM server. Hipchat can only be used in the plan notifications area as shown here:

Configure Bamboo plans to send notifications to your Hipchat server

You can get Bamboo plan notifications in rooms hosted by your own organization's Hipchat Server instance:

1. Specify the hipchat.api.url system property that is used when Bamboo is starting. The hipchat.api.url value must be set to the URL of the organization's Hipchat server. Example: -Dhipchat.api.url=https://example.com/
2. Set up plan notifications in Bamboo that use the 'Hipchat' Recipient type.
3. Use a Hipchat V1 token in the API Token field.
4. Choose your Room Name or ID.
5. Check the Notify flag to send pop-up notification to the room.

For more information about setting up your own Hipchat server, see System Requirements for Hipchat Server.
Integrating Bamboo with Hipchat v5.15

Bamboo can send notifications about build results to Hipchat so you can find out immediately about the success or failure of your builds.

You get Bamboo notifications in your chat room for events such as:

- when a build passes or fails
- when you are assigned responsibility for a breaking build
- when a build you are responsible for has been fixed
- when a manual stage of a build is ready to be run
- when a deployment starts, and completes

...and many other notification events.

You can configure Bamboo to send notifications to rooms whether they’re hosted by Atlassian on hipchat.com, or by your own organization’s Hipchat Server instance:

- Configure Bamboo plans to send notifications to a room in hipchat.com
- Configure Bamboo plans to send notifications to your Hipchat server

Configure Bamboo plans to send notifications to a room in hipchat.com

To get notifications in rooms hosted by Atlassian on hipchat.com:

1. Sign up for a Hipchat account.
2. Set up plan notifications in Bamboo that use the ‘Hipchat’ Recipient type.

Note that Bamboo does not yet support using Hipchat as a global IM server. Hipchat can only be used in the plan notifications area as shown here:

Configure Bamboo plans to send notifications to your Hipchat server

You can get Bamboo plan notifications in rooms hosted by your own organization’s Hipchat Server instance:

1. Install the Hipchat Server’s SSL root or primary certificate in `<JAVA_HOME>/jre/lib/security/cacerts` keystore on the Bamboo host machine and restart Bamboo. Applicable if you’re using a self-signed or internally signed SSL certificate.
2. Specify the `hipchat.api.url` system property that is used when Bamboo is starting, by adding `-Dhipchat.api.url=<my_hipchat_api_url>` to your JVM arguments as per Configuring system properties.
3. Set up plan notifications in Bamboo that use the ‘Hipchat’ Recipient type.
4. Use a Hipchat V1 token in the API Token field.
5. Choose your Room Name or ID.
6. Check the Notify flag to send pop-up notification to the room.

For more information about setting up your own Hipchat server, see System Requirements for Hipchat Server.

Integrating Bamboo with Hipchat v6.0
Bamboo can send notifications about build results to Hipchat so you can find out immediately about the success or failure of your builds.

You get Bamboo notifications in your chat room for events such as:

- when a build passes or fails
- when you are assigned responsibility for a breaking build
- when a build you are responsible for has been fixed
- when a manual stage of a build is ready to be run
- when a deployment starts, and completes

...and many other notification events.

You can configure Bamboo to send notifications to rooms whether they're hosted by Atlassian on hipchat.com, or by your own organization's Hipchat Server instance:

- Configure Bamboo plans to send notifications to a room in hipchat.com
- Configure Bamboo plans to send notifications to your Hipchat server

Configure Bamboo plans to send notifications to a room in hipchat.com
To get notifications in rooms hosted by Atlassian on hipchat.com:

1. Sign up for a Hipchat account.
2. Set up plan notifications in Bamboo that use the 'Hipchat' Recipient type.

Configure Bamboo plans to send notifications to your Hipchat server
You can get Bamboo plan notifications in rooms hosted by your own organization's Hipchat Server instance:

1. Install the Hipchat Server's SSL root or primary certificate in <JAVA_HOME>/jre/lib/security/cacerts keystore on the Bamboo host machine and restart Bamboo. Applicable if you're using a self-signed or internally signed SSL certificate.
2. Specify the hipchat.api.url system property that is used when Bamboo is starting, by adding `-Dhipchat.api.url=<my_hipchat_url>` to your JVM arguments as per Configuring system properties.
3. Set up plan notifications in Bamboo that use the ‘Hipchat’ Recipient type.
4. Use a Hipchat V1 token in the API Token field.
5. Choose your Room Name or ID.
6. Check the Notify flag to send pop-up notification to the room.

For more information about setting up your own Hipchat server, see System Requirements for Hipchat Server.

### Integrating Bamboo with Hipchat v6.1

Bamboo can send notifications about build results to Hipchat so you can find out immediately about the success or failure of your builds.

You get Bamboo notifications in your chat room for events such as:

- when a build passes or fails
- when you are assigned responsibility for a breaking build
- when a build you are responsible for has been fixed
- when a manual stage of a build is ready to be run
- when a deployment starts, and completes

...and many other notification events.

You can configure Bamboo to send notifications to rooms whether they’re hosted by Atlassian on hipchat.com, or by your own organization’s Hipchat Server instance:

- Configure Bamboo plans to send notifications to a room in hipchat.com
- Configure Bamboo plans to send notifications to your Hipchat server

**Configure Bamboo plans to send notifications to a room in hipchat.com**

To get notifications in rooms hosted by Atlassian on hipchat.com:

1. Sign up for a Hipchat account.
2. Set up plan notifications in Bamboo that use the ‘Hipchat’ Recipient type.

Note that Bamboo does not yet support using Hipchat as a global IM server. Hipchat can only be used in the plan notifications area as shown here:

**Configure Bamboo plans to send notifications to your Hipchat server**
You can get Bamboo plan notifications in rooms hosted by your own organization's Hipchat Server instance:

1. Install the Hipchat Server's SSL root or primary certificate in `<JAVA_HOME>/jre/lib/security/cacerts` keystores on the Bamboo host machine and restart Bamboo. Applicable if you're using a self-signed or internally signed SSL certificate.
2. Specify the `hipchat.api.url` system property that is used when Bamboo is starting, by adding `-Dhipchat.api.url=my_hipchat_url` to your JVM arguments as per Configuring system properties.
3. Set up plan notifications in Bamboo that use the 'Hipchat' Recipient type.
4. Use a Hipchat V1 token in the API Token field.
5. Choose your Room Name or ID.
6. Check the Notify flag to send pop-up notification to the room.

For more information about setting up your own Hipchat server, see System Requirements for Hipchat Server.

### Integrating Bamboo with Hipchat v6.4

Bamboo can send notifications about build results to Hipchat so you can find out immediately about the success or failure of your builds.

You get Bamboo notifications in your chat room for events such as:

- when a build passes or fails
- when you are assigned responsibility for a breaking build
- when a build you are responsible for has been fixed
- when a manual stage of a build is ready to be run
- when a deployment starts, and completes

...and many other notification events.

You can configure Bamboo to send notifications to rooms whether they're hosted by Atlassian on hipchat.com, or by your own organization's Hipchat Server instance:

- Configure Bamboo plans to send notifications to a room in hipchat.com
- Configure Bamboo plans to send notifications to your Hipchat server

**Configure Bamboo plans to send notifications to a room in hipchat.com**

To get notifications in rooms hosted by Atlassian on hipchat.com:

1. Sign up for a Hipchat account.
2. Set up plan notifications in Bamboo that use the 'Hipchat' Recipient type.

Note that Bamboo does not yet support using Hipchat as a global IM server. Hipchat can only be used in the plan notifications area as shown here:
**Configure Bamboo plans to send notifications to your Hipchat server**

You can get Bamboo plan notifications in rooms hosted by your own organization's Hipchat Server instance:

1. Install the Hipchat Server's SSL root or primary certificate in `<JAVA_HOME>/jre/lib/security/cacerts` keystore on the Bamboo host machine and restart Bamboo. \( ^{i} \) Applicable if you're using a self-signed or internally signed SSL certificate.
2. Specify the `hipchat.api.url` system property that is used when Bamboo is starting, by adding `-Dhipchat.api.url=<my_hipchat_url>` to your JVM arguments as per Configuring system properties.

   Please be sure to include the protocol in the `<hipchat.api.url>` value, for example:
   - `Dhipchat.api.url=http://hipchat.mydomain.com`
   - `Dhipchat.api.url=https://hipchat.mydomain.com`

3. Set up plan notifications in Bamboo that use the 'Hipchat' Recipient type.
4. Use a Hipchat V1 token in the API Token field.
5. Choose your Room Name or ID.
6. Check the Notify flag to send pop-up notification to the room.

For more information about setting up your own Hipchat server, see System Requirements for Hipchat Server.

**Integrating Bamboo with Hipchat v6.5**

Bamboo can send notifications about build results to Hipchat so you can find out immediately about the success or failure of your builds.

You get Bamboo notifications in your chat room for events such as:

- when a build passes or fails
- when you are assigned responsibility for a breaking build
- when a build you are responsible for has been fixed
- when a manual stage of a build is ready to be run
- when a deployment starts, and completes

...and many other notification events.

You can configure Bamboo to send notifications to rooms whether they're hosted by Atlassian on hipchat.com, or by your own organization's Hipchat Server instance:

- Configure Bamboo plans to send notifications to a room in hipchat.com
- Configure Bamboo plans to send notifications to your Hipchat server

**Configure Bamboo plans to send notifications to a room in hipchat.com**

To get notifications in rooms hosted by Atlassian on hipchat.com:

1. Sign up for a Hipchat account.
2. Set up plan notifications in Bamboo that use the 'Hipchat' Recipient type.

Note that Bamboo does not yet support using Hipchat as a global IM server. Hipchat can only be used in the plan notifications area as shown here:
### Configure Bamboo plans to send notifications to your Hipchat server

You can get Bamboo plan notifications in rooms hosted by your own organization’s Hipchat Server instance:

1. Install the Hipchat Server’s SSL root or primary certificate in `<JAVA_HOME>/jre/lib/security/cacerts` keystore on the Bamboo host machine and restart Bamboo. 
   - Applicable if you’re using a self-signed or internally signed SSL certificate.
2. Specify the `hipchat.api.url` system property that is used when Bamboo is starting, by adding `-Dhipchat.api.url=<my_hipchat_url>` to your JVM arguments as per Configuring system properties.

```
Please be sure to include the protocol in the <hipchat.api.url> value, for example:
- Dhipchat.api.url=http://hipchat.mydomain.com
- Dhipchat.api.url=https://hipchat.mydomain.com
```

3. Set up plan notifications in Bamboo that use the ‘Hipchat’ Recipient type.
4. Use a Hipchat V1 token in the API Token field.
5. Choose your Room Name or ID.
6. Check the Notify flag to send pop-up notification to the room.

For more information about setting up your own Hipchat server, see System Requirements for Hipchat Server.

### Integrating Bamboo with Confluence

Integrating Bamboo with Atlassian’s Confluence combines Bamboo’s continuous integration capabilities with your wiki to give you a unified view of your software development project.

When Bamboo is integrated with Confluence, you can add the following Bamboo gadgets to a Confluence wiki page:

- Bamboo Charts
- Bamboo Plan Summary Chart
- Bamboo Plan Status

Configuring Bamboo and Confluence to work together simply requires you to set up an application link (two-way) between Confluence and Bamboo.
Before you begin

Version Requirements

<table>
<thead>
<tr>
<th>Application</th>
<th>Version Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bamboo</td>
<td>Version 5.2 or later</td>
</tr>
<tr>
<td>Confluence</td>
<td>Version 3.5.9 or later</td>
</tr>
</tbody>
</table>

Set up an application link

Before you begin:
- Security Considerations — The instructions below recommend setting up authentication for the application link between Confluence and Bamboo. Please ensure that you read the Security implications for each authentication type (Applinks documentation). For example, if you use basic HTTP authentication for the Confluence to Bamboo link, you must specify a user that Confluence uses to log in to Bamboo. Hence, this user's Bamboo permissions will be used (not the Bamboo permissions of the user who is currently logged into Confluence).
- You will need to set up a two-way link, i.e. select the 'Create a link back to this server' option when adding the application link.
- You will need to configure either OAuth or Trusted Apps authentication for your application link. See Linking to Another Application instructions.

Congratulations! You have successfully integrated Bamboo and Confluence.

Try your new configuration

You may wish to read about how to use these two applications together in the following pages:
- Add Bamboo gadgets to Confluence, see Registering External Gadgets (Confluence documentation).

Notes

If you need further help, please raise a support request in our support system, in the Bamboo project. You may also want to view articles in the Bamboo Knowledge Base and browse our forums.

Integrating Bamboo with Stash

When you integrate Bamboo with Atlassian's Bitbucket Server (formerly Stash) Git repository management solution, commit, branch, build and deployment information is shared for users of both applications.

On this page:
- Benefits of integration
- Configuration

Benefits of integration

We recommend integrating with Bitbucket Server.

Stash tells Bamboo when to build
- When a developer pushes to a repository the build is automatically started.

Stash tells Bamboo when to update plan branches to match changes in repository branches
- When a developer pushes a new branch to a repository a branch plan is automatically created.
- When a developer deletes a branch in a repository, the branch plan is automatically deleted or disabled.

Stash commits are displayed in the relevant Bamboo builds
In Bamboo, you can view all of the commits involved in the build, allowing you to accurately track changes:

Simply click on a changeset to go to Stash, where you can see the commit diff for all of the files that are part of the build.

Bamboo notifies Stash automatically about build results:

- Build notifications are automatically enabled when you link a build plan to a Stash repository.
- Notifications are sent to all linked Stash servers.
- You see the build results status for a commit when viewing any commit or pull request in Stash, so you can easily check the build status of a branch when deciding whether to merge changes:

Stash displays the overall status of the build results. The status is 'passed' if all the different builds (for example, unit tests, functional tests, deploy to staging) have succeeded, and 'failed' if at least one run failed for any of those.
For example, when viewing the Commits tab for a Stash project, you will see icons that indicate the status of the latest build results. The red 'fail' icon is displayed if there is at least one failed build run for the commit.

Note that the legacy Stash notification type is deprecated – it is still available in Bamboo 5.6 but will be removed in Bamboo 5.7.

**Configuration**

There are just a few simple configuration steps to get the integrations described above with Bamboo (versions 5.6 and later) and Stash (versions 3.1 and later).

Bamboo will be automatically configured to respond to repository events published by Stash, and to notify Stash about build results – you don't have to configure repository polling for new commits anymore in Bamboo, or set up dedicated web hooks in your Stash instance.

1. **Create an Application Link**
   
   You only need to do this once for each pair of Stash and Bamboo instances.

   See [Linking to another application](#).

   Once linked, all the Stash repositories are available to your plans in Bamboo.

2. **Choose the Stash repository for the Bamboo plan**

   Create a build plan (if necessary) and specify the repository in the plan (or job) configuration.

   See [Bitbucket Server](#) (formerly Stash) for more information about using Bitbucket Server source repositories in Bamboo.

3. **Build!**

   **Integrating Bamboo with Stash v5.14**

   When you integrate Bamboo with Atlassian's Bitbucket Server (formerly Stash) Git repository management solution, commit, branch, build and deployment information is shared for users of both applications.

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Benefits of integration

We recommend integrating with Bitbucket Server.

Stash tells Bamboo when to build

- When a developer pushes to a repository the build is automatically started.

Stash tells Bamboo when to update plan branches to match changes in repository branches

- When a developer pushes a new branch to a repository a branch plan is automatically created.
- When a developer deletes a branch in a repository, the branch plan is automatically deleted or disabled.

Stash commits are displayed in the relevant Bamboo builds

- In Bamboo, you can view all of the commits involved in the build, allowing you to accurately track changes:

  ![Code commits](image)

  - Simply click on a changeset to go to Stash, where you can see the commit diff for all of the files that are part of the build.

Bamboo notifies Stash automatically about build results

- Build notifications are automatically enabled when you link a build plan to a Stash repository.
- Notifications are sent to all linked Stash servers.
- You see the build results status for a commit when viewing any commit or pull request in Stash, so you can easily check the build status of a branch when deciding whether to merge changes:

  ![Commit Date](image)

  - Click a build status icon in Stash to see further details:
Stash displays the overall status of the build results. The status is 'passed' if all the different builds (for example, unit tests, functional tests, deploy to staging) have succeeded, and 'failed' if at least one run failed for any of those.

For example, when viewing the Commits tab for a Stash project, you will see icons that indicate the status of the latest build results. The red 'fail' icon is displayed if there is at least one failed build run for the commit.

Note that the legacy Stash notification type is deprecated – it is still available in Bamboo 5.6 but will be removed in Bamboo 5.7.

**Configuration**

There are just a few simple configuration steps to get the integrations described above with Bamboo (versions 5.6 and later) and Stash (versions 3.1 and later).

Bamboo will be automatically configured to respond to repository events published by Stash, and to notify Stash about build results – you don't have to configure repository polling for new commits anymore in Bamboo, or set up dedicated web hooks in your Stash instance.
1. Create an Application Link
You only need to do this once for each pair of Stash and Bamboo instances.
See Linking to another application.
Once linked, all the Stash repositories are available to your plans in Bamboo.

2. Choose the Stash repository for the Bamboo plan
Create a build plan (if necessary) and specify the repository in the plan (or job) configuration.
See Bitbucket Server (formerly Stash) for more information about using Bitbucket Server source repositories in Bamboo.

3. Build!

Integrating Bamboo with Fisheye
When Bamboo is integrated with Atlassian's Fisheye, you can:

- view the code changes that triggered a build
- explore a failed build in Fisheye and jump directly into the changeset that broke the build
- view the history of the changeset to see what the author was trying to fix
- analyze the change using the side-by-side diff view
- open the relevant files in your IDE.

A Bamboo administrator can make links to individual source-code files available by connecting the plan to the source repository, as described below.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

Related pages:
- Integrating Bamboo with Atlassian applications
- Linking to Another Application

To integrate Bamboo with Fisheye:

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Click on a repository name, and then click Advanced Options.
3. Choose Web Repository > Fisheye.
4. Specify the Fisheye URL, Repository Name and Repository Path.

Screenshot: Specifying a Fisheye project in Bamboo
If links to Fisheye are broken in Bamboo builds, make sure that the Repository Path configured in Bamboo matches the Repository Location (under 'SCM Details') in Fisheye, for the specific repository.

Integrating Bamboo with Fisheye v5.14

When Bamboo is integrated with Atlassian's Fisheye, you can:

- view the code changes that triggered a build
- explore a failed build in Fisheye and jump directly into the changeset that broke the build
- view the history of the changeset to see what the author was trying to fix
- analyze the change using the side-by-side diff view
- open the relevant files in your IDE.

A Bamboo administrator can make links to individual source-code files available by connecting the plan to the source repository, as described below.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

To integrate Bamboo with Fisheye:

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Click on a repository name, and then click Advanced Options.
3. Choose Web Repository > Fisheye.
4. Specify the Fisheye URL, Repository Name and Repository Path.

Integrating Bamboo with Fisheye v6.5

When Bamboo is integrated with Atlassian’s Fisheye, you can:

- view the code changes that triggered a build
- explore a failed build in Fisheye and jump directly into the changeset that broke the build
- view the history of the changeset to see what the author was trying to fix
- analyze the change using the side-by-side diff view
- open the relevant files in your IDE.

A Bamboo administrator can make links to individual source-code files available by connecting the plan to the source repository, as described below.

You can specify repositories at the following levels in Bamboo:

- global – repositories are available to all plans in Bamboo.
- plan – repositories are available to all jobs in the Bamboo plan.
- job – repositories are available to all tasks in the Bamboo job.

The recommended approach is to set up linked source repositories at the global level – see Linking to source code repositories.

Related pages:

- Integrating Bamboo with Atlassian applications
- Linking to Another Application

To integrate Bamboo with Fisheye:

1. Navigate to the repository configuration for a linked repository, plan or job. See Linking to source code repositories.
2. Click on a repository name, and then click Advanced Options.
3. Choose Web Repository > Fisheye.
4. Specify the Fisheye URL, Repository Name and Repository Path.

Screenshot: Specifying a Fisheye project in Bamboo
Integrating Bamboo with Bitbucket Server

When you integrate Bamboo with Atlassian's Bitbucket Server Git repository management solution, commit, branch, build and deployment information is shared for users of both applications.

On this page:
- Benefits of integration
- Configuration

Benefits of integration

When Bamboo (versions 5.6 and later) and Bitbucket Server are integrated, you and your team get all the following advantages:

Bitbucket Server tells Bamboo when to build
- When a developer pushes to a repository the build is automatically started.

Bitbucket Server tells Bamboo when to update plan branches to match changes in repository branches
- When a developer pushes a new branch to a repository a branch plan is automatically created.
- When a developer deletes a branch in a repository, the branch plan is automatically deleted or disabled.

Bitbucket Server commits are displayed in the relevant Bamboo builds
- In Bamboo, you can view all of the commits involved in the build, allowing you to accurately track changes:
  - Simply click on a changeset to go to Bitbucket Server, where you can see the commit diff for all of the files that are part of the build.

Bamboo notifies Bitbucket Server automatically about build results
- Build notifications are automatically enabled when you link a build plan to a Bitbucket Server repository.
- Notifications are sent to all linked Bitbucket servers.
• You see the build results status for a commit when viewing any commit or pull request in Bitbucket Server, so you can easily check
the build status of a branch when deciding whether to merge changes.
• Click a build status icon in Bitbucket Server to see further details:

  Bitbucket Server displays the overall status of the build results. The status is ‘passed’ if all the different builds (for example, unit tests,
  functional tests, deploy to staging) have succeeded, and ‘failed’ if at least one run failed for any of those.

  For example, when viewing the Commits tab for a Bitbucket Server project, you will see icons that indicate the status of the latest build
  results. The red ‘fail’ icon is displayed if there is at least one failed build run for the commit.

  Note that the legacy Bitbucket Server notification type is deprecated – it is still available in Bamboo 5.6 but will be removed in Bamboo 5.7.

  **Bamboo provides support for Pull Request**

  Starting from version 6.0, Bamboo can create plan branches by pull requests. Create a pull request when ready to share your work with
  teammates and the CI system. Bamboo will detect new pull requests and create plan branch.

  Note that Bamboo doesn’t provide pull request support for forked repositories yet.

  **Configuration**

  There are just a few simple configuration steps to get the integrations described above with Bamboo (versions 5.6 and later) and
  Bitbucket Server.

  Bamboo will be automatically configured to respond to repository events published by Bitbucket Server, and to notify Bitbucket Server about
  build results – you don't have to configure repository polling for new commits anymore in Bamboo, or set up dedicated web hooks in
  your Bitbucket Server instance.
1. Create an Application Link

You only need to do this once for each pair of Bitbucket Server and Bamboo instances.
See Linking to another application.

Once linked, all the Bitbucket Server repositories are available to your plans in Bamboo.

2. Choose the Bitbucket Server repository for the Bamboo plan

Create a build plan (if necessary) and specify the repository in the plan (or job) configuration.

To connect to a Bitbucket Server repository, select Bitbucket Server / Stash and provide the Bitbucket Server details.
You must enable the SSH access on Bitbucket Server, otherwise the integration features won't work and you will have to provide an alternative HTTP repository type to connect to the Bitbucket Server repository.

See Bitbucket Server for more information about using Bitbucket Server source repositories in Bamboo.

3. Build!

.Integrating Bamboo with Bitbucket Server v5.14

When you integrate Bamboo with Atlassian's Bitbucket Server Git repository management solution, commit, branch, build and deployment information is shared for users of both applications.

You must enable the SSH access on Bitbucket Server, otherwise the integration features won't work and you will have to provide an alternative HTTP repository type to connect to the Bitbucket Server repository.

See Bitbucket Server for more information about using Bitbucket Server source repositories in Bamboo.

3. Build!

.Integrating Bamboo with Atlassian applications v6.1

You can integrate Bamboo with the following Atlassian applications:

<table>
<thead>
<tr>
<th>Jira</th>
<th>When Bamboo is integrated with a Jira application, you can:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• See Bamboo development activity in Jira applications. Learn more...</td>
</tr>
<tr>
<td></td>
<td>• View detailed Bamboo build result information</td>
</tr>
<tr>
<td></td>
<td>• View detailed Bamboo deployment information</td>
</tr>
<tr>
<td></td>
<td>• Run a Bamboo build when releasing a Jira Software Server version</td>
</tr>
<tr>
<td></td>
<td>• Have Bamboo automatically link a plan branch with an issue</td>
</tr>
<tr>
<td></td>
<td>• View the Jira application issues linked to a build result</td>
</tr>
<tr>
<td></td>
<td>• View the Bamboo builds that relate to a Jira application project or version</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Hipchat</th>
<th>When Bamboo is integrated with Hipchat, you can get notifications from Bamboo for things like:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• when a build passes or fails</td>
</tr>
<tr>
<td></td>
<td>• when you are assigned responsibility for a breaking build</td>
</tr>
<tr>
<td></td>
<td>• when a build you are responsible for has been fixed</td>
</tr>
<tr>
<td></td>
<td>• when a manual stage of a build is ready to be run</td>
</tr>
<tr>
<td></td>
<td>• when a deployment starts, and completes</td>
</tr>
<tr>
<td></td>
<td>...and many other notification events.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bitbucket</th>
<th>When Bamboo is integrated with Bitbucket Server:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Bamboo will automatically run a build when changes are pushed to the Bitbucket repository, without needing to configure polling.</td>
</tr>
<tr>
<td></td>
<td>• Bamboo will automatically update plan branches when a developer pushes a new branch to the repository (or deletes a branch).</td>
</tr>
<tr>
<td></td>
<td>• You can click through to Bitbucket to see the commit diff for all files that are part of the changeset.</td>
</tr>
<tr>
<td></td>
<td>• Bitbucket commits that are part of a build are displayed in Bamboo.</td>
</tr>
<tr>
<td></td>
<td>• Build results are notified to Bitbucket (and displayed for the associated commits and pull requests).</td>
</tr>
</tbody>
</table>
When Bamboo is integrated with Confluence, you can add the following Bamboo gadgets to a Confluence wiki page:

- Bamboo Charts
- Bamboo Plan Summary Chart
- Bamboo Plan Status

When Bamboo is integrated with Fisheye, you can:

- view the code changes that triggered a build
- explore a failed build in Fisheye and jump directly into the changeset that broke the build
- view the history of the changeset to see what the author was trying to fix
- analyze the change using the side-by-side diff view
- open the relevant files in your IDE.

When Bamboo is integrated with Clover, you can:

- View code-coverage details (i.e. the percentage of code covered by tests) for each build result
- View code-coverage trends for a job over a period of time
- View the code-coverage summary for the job.

See The big list of Atlassian gadgets.

Integrating Bamboo with Atlassian applications v5.14

You can integrate Bamboo with the following Atlassian applications:

When Bamboo is integrated with a Jira application, you can:

- See Bamboo development activity in Jira applications. Learn more...
- View detailed Bamboo build result information
- View detailed Bamboo deployment information
- Run a Bamboo build when releasing a Jira Software Server version
- Have Bamboo automatically link a plan branch with an issue
- View the Jira application issues linked to a build result
- View the Bamboo builds that relate to a Jira application project or version

When Bamboo is integrated with HipChat, you can get notifications from Bamboo for things like:

- when a build passes or fails
- when you are assigned responsibility for a breaking build
- when a build you are responsible for has been fixed
- when a manual stage of a build is ready to be run
- when a deployment starts, and completes
- ...and many other notification events.

When Bamboo is integrated with Bitbucket Server:

- Bamboo will automatically run a build when changes are pushed to the Bitbucket repository, without needing to configure polling.
- Bamboo will automatically update plan branches when a developer pushes a new branch to the repository (or deletes a branch).
- You can click through to Bitbucket to see the commit diff for all files that are part of the changeset.
- Bitbucket commits that are part of a build are displayed in Bamboo.
- Build results are notified to Bitbucket (and displayed for the associated commits and pull requests).
When Bamboo is integrated with [Confluence](https://confluence.atlassian.com), you can add the following Bamboo gadgets to a Confluence wiki page:

- Bamboo Charts
- Bamboo Plan Summary Chart
- Bamboo Plan Status

When Bamboo is integrated with [Fisheye](https://fisheye.atlassian.com), you can:

- view the code changes that triggered a build
- explore a failed build in Fisheye and jump directly into the changeset that broke the build
- view the history of the changeset to see what the author was trying to fix
- analyze the change using the side-by-side diff view
- open the relevant files in your IDE.

When Bamboo is integrated with [Clover](https://clover.appdynamics.com), you can:

- View code-coverage details (i.e. the percentage of code covered by tests) for each build result
- View code-coverage trends for a job over a period of time
- View the code-coverage summary for the job.

See [The big list of Atlassian gadgets](https://confluence.atlassian.com/pages/standalone/45088846).

## Managing your user profile

You can manage your user details, password, notifications preferences and other preferences using your user profile.

### To change your personal details:

1. Go to your name (the ‘Profile’ menu) at the top of the page and choose **Profile**.
2. Click **Edit Profile**.
3. Update your personal details as required.

Note that if your user profile is managed using a single sign-on application, like Atlassian’s Crowd, you will only be able to edit your **Instant Messaging Address** and **Source Repository Alias**.

### Changing your password

To change your Bamboo password:

1. Go to your name (the ‘Profile’ menu) at the top of the page and choose **Profile**.
2. Click **Change Password**.
3. Complete the form.

*If your password is managed via a single sign-on application, like Atlassian’s Crowd, this function will not be available.*

### Changing your notification preferences

Notifications in Bamboo are triggered by a range of events for a **plan**, including build completion, build outcomes and comments being posted against build results. You can choose whether to receive notifications by email, IM, both or neither.

You can see which notifications are currently applicable to you, in your user profile: go to your avatar (the ‘Profile’ menu) at the top of the page, choose **Profile**, and then click the **Notifications** tab.

You must have the ‘Edit’ permission for a plan to add or remove notifications for it.

To change your notification preferences:

1. Go to your avatar (the ‘Profile’ menu) at the top of the page and choose **Profile**.

### Related pages:

- Changing your password
- Changing your notification preferences
- Associating your author name with your user profile
- Configuring notifications for a plan and its jobs
- Managing your user profile
2. Click **Notifications**, then **Edit notification preferences**, on the right.
3. Choose an option from **How would you like Bamboo to send you notifications**. If you choose one of the IM options, you also need to specify an **Instant messaging address** on the **Personal Details** tab.
4. Choose an **Email format** option.
5. Click **Save**.

**Screenshot: User profile**

<table>
<thead>
<tr>
<th>Personal Details</th>
<th>Notifications</th>
<th>OAuth Access Tokens</th>
</tr>
</thead>
</table>

**Edit user profile**

**How would you like Bamboo to send you notifications**

- [ ] **Send email and instant message**

**Email format**

- [ ] **Text email**
- [ ] **HTML email (multipart)**

Please specify the format you want your emails sent in.

[Save] [Cancel]

**Associating your author name with your user profile**

An author is any person who checks in code to a repository that is associated with a Bamboo plan. An author need not be a Bamboo user. Your **Author Name** is your login name for the source-code repository. This is the identity that the SCM associates with tasks you perform on the repository. However, if this is not the login you use for Bamboo, then Bamboo may not be able to make the connection between your SCM login and your Bamboo login. See also **Managing authors**.

When your Bamboo user profile is associated with your author name, then Bamboo is able to:

- match your SCM activity with your Bamboo activity.
- show information about your recent builds on your 'My Bamboo' tab.
- show a **User Details** tab in your 'Author' information.

**To associate your author name with your user profile:**

1. Go to your **name** (the 'Profile' menu) at the top of the page and choose **Profile**.
2. Click **Edit Profile**.
3. Select your author name from the **Source Repository Aliases** list. If your name does not appear in the list, click **Add Alias**. Note that your author name (alias) need not be identical to your user name.
4. Click **Save**.

You can link more than one author name to a Bamboo user name.

**Related pages:**

- Managing your user profile
- Managing authors

**Bamboo variables**

Variables can be used to make values available when building plans in Bamboo.

- **Build-specific variables** are evaluated by Bamboo dynamically at build time. The source of a build-specific variable can either be a Bamboo property or one of the default plugins (assuming it is enabled).
- **Deployment variables** are available when deploying a project.
- **System variables** also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- **Global variables** are defined across your entire Bamboo instance, and have the same (static) value for every plan that is built by Bamboo. See **Defining global variables**.
- **Plan variables** are similar to global variables, but are defined for specific plans. Plan variables override global variables with the same name. You can also override a plan variable for a build if you trigger the build manually. See **Defining plan variables**.

**Using variables**

Variables can be used in all fields of a task or deployment, with the exception of password fields. Use the following format when referencing a variable:
You can override a plan variable for a build, if you trigger the build manually. See Triggering a plan build manually.

You can reference a variable from another variables, e.g. consider having the following variables:

- var1 = Hello
- var2 = world

You can create another variable which references the two other ones

```
greet
${bamboo.var1} ${bamboo.var2}!
```

Bamboo will resolve the variable as Hello World!

You can:

- reference a global or context specific variable in a build plan or deployment project
- reference a variable which references another one, deep recursion is allowed

There are couple of limitations:

- referencing a variable which isn't defined is an error, whole build or deployment will fail if you reference such variable
- cycles are not allowed and are considered as build or deployment project error.

### Defining custom variables

You can define your own custom variables, using a similar format to that above, however you cannot create a variable name that is already in use by Bamboo.

For information on how to define your own variables in Bamboo, see:

- Defining global variables
- Defining plan variables
- Defining deployment environment variables

### Build-specific variables

The following build-specific variables are available by default:

- **System variables** apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- In the variable names from the table, `<position>` is an optional parameter that specifies the position of the repository in the plan's repository list. If omitted, the first repository in the list is used.
- Third-party repository plugins can expose their own variables.
<table>
<thead>
<tr>
<th>Build-specific variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildKey</td>
<td>The job key for the current job, in the form PROJECT-PLAN-JOB, e.g. BAM-MAIN-JOBX</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the current plan, in the form PROJECT-PLAN, e.g. BAM-MAIN</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the current plan (without project part), e.g. MAIN</td>
</tr>
<tr>
<td>bamboo.shortJobKey</td>
<td>The short key of the current job (without project and plan parts), e.g. JOBX</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The result key when this job executes, in the form PROJECT-PLAN-JOB-BUILD e.g. BAM-BOO-JOB1-8, where '8' is the build number. For deployment projects this variable will not have the JOB component e.g. PROJ-TP-6.</td>
</tr>
<tr>
<td>bamboo.buildResultsUrl</td>
<td>The URL of the result in Bamboo once the job has finished executing.</td>
</tr>
<tr>
<td>or</td>
<td>bamboo.resultsUrl</td>
</tr>
<tr>
<td>bamboo.buildNumber</td>
<td>The Bamboo build number, e.g. 123</td>
</tr>
<tr>
<td>bamboo.buildPlanName</td>
<td>The Bamboo job name e.g. Some Project name - Some plan name - Some job name</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The current plan's name e.g. Some project name - Some plan name</td>
</tr>
<tr>
<td>bamboo.shortPlanName</td>
<td>The current plan's name without project part, e.g. Some plan name</td>
</tr>
<tr>
<td>bamboo.shortJobName</td>
<td>The current job's name without project and plan parts, e.g. Some job name</td>
</tr>
<tr>
<td>bamboo.buildTimeStamp</td>
<td>The time when build was started in ISO 8601 format e.g. 2010-01-01T01:00:00.000+01:00</td>
</tr>
<tr>
<td>bamboo.agentId</td>
<td>The ID of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td>bamboo.agentWorkingDirectory</td>
<td>The path to the working directory on the agent, for example &lt;HOME&gt;/xml-data/build-dir. The agent working directory is not the same as the build working directory described below.</td>
</tr>
<tr>
<td>bamboo.build.working.directory</td>
<td>The working directory on which the build is being executed, for example &lt;HOME&gt;/xml-data/build-dir/AVT-JOB1.</td>
</tr>
<tr>
<td>bamboo.ManualBuildTriggerReason.userName</td>
<td>The user who triggered the manual build.</td>
</tr>
</tbody>
</table>

**Generic repository variables**

| bamboo.planRepository.<position>.branchName | The name of the branch in the repository (depends on availability from the VCS used) e.g. default |
| bamboo.planRepository.<position>.name | The name of of the repository, as shown in the repository for the plan e.g. Mercurial |
| bamboo.planRepository.<position>.revision | The revision use to build this release. Format depends on the VCS used. |
| bamboo.planRepository.<position>.previousRevision | The previous revision number (this might not exist, for example for the initial build). |
| bamboo.planRepository.<position>.type | The type of the repository, as defined by a repository plugin e.g. hg, svn, git |

**Subversion**

| bamboo.planRepository.<position>.username | User name, used for repository authentication. |
| bamboo.planRepository.<position>.repositoryUrl | The repository URL. |
### CVS

<td>The branch</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.username</td>
<td>User name, used for repository authentication.</td>
</tr>
</tbody>
</table>

- System variables also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- In the variable names from the table above, `<position>` is an optional parameter that specifies the position of the repository in the plan's repository list. If omitted, the first repository in the list is used.
- Third-party repository plugins can expose their own variables.

### Build dependency variables

The following build dependency variables are also available:

<table>
<thead>
<tr>
<th>Build-specific variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.dependency.parent.#</td>
<td>Allows a child build to query the build key of the triggering parent build, where # represents the position in the build tree - 0 at the top, 1 the following, and so on. The <code>${bamboo.dependency.parent.0}</code> variable can be viewed in the child plan's metadata tab.</td>
</tr>
<tr>
<td>bamboo.dependency.parent.total</td>
<td>The total # of parent builds.</td>
</tr>
</tbody>
</table>

### Deployment variables

Bamboo manages a number of standard reserved variables that are available when deploying a project.

Variables later in the following list override the previous ones in case of repeating names:

- global variables
- release variables as defined below
- user variables defined at environment level
- the autogenerated variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.agentId</td>
<td>The id of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td>bamboo.agentWorkingDirectory</td>
<td>The path to the working directory on the agent. This is not the same as the Bamboo working directory.</td>
</tr>
<tr>
<td>bamboo.build.working.directory</td>
<td>The path to the working directory for Bamboo. This is used by both the build plan and the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.environment</td>
<td>The name of the environment that the release is to be deployed to.</td>
</tr>
</tbody>
</table>
### bamboo.deploy.project
The name of the deployment project.

### bamboo.deploy.rollback
True if the release being deployed is older than the release being replaced.

### bamboo.deploy.release
### bamboo.deploy.version
The name of the release that is being deployed. Either .release or .version can be used - both return the name of the release being deployed.

### bamboo.deploy.release.previous
### bamboo.deploy.version.previous
The name of the release that is being replaced (if available). Either .release or .version can be used - both return the name of the release being replaced.

### bamboo.resultsUrl
The URL to the screen in Bamboo that displays build results.

You can generate variables of your own, using a similar format, however you cannot create a variable that is already in use by Bamboo. See [Defining deployment environment variables](#) for more information.

## Releases variables

Bamboo makes the following types of variables available for deployment releases:

- Snapshots of values for **global variables**.
- Snapshots of values for **plan variables**.
- Snapshots of values of repository variables.
- The autogenerated release variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildNumber</td>
<td>The build result from which the release is created.</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The key of the build result from which the release is created e.g. KUNG-FOO-JOB1-35</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the plan related to the release e.g. KUNG-FOO</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The name of the plan related to the release e.g. Kung - Foo</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the plan related to the release (without project part), e.g. MAIN</td>
</tr>
<tr>
<td>bamboo.shortPlanName</td>
<td>The plan's name without project part, e.g. Some plan name</td>
</tr>
</tbody>
</table>

Note that several of the variables in the above table are actually those associated with the build plan.

## System variables

The usage format for all system variables is:

```
${system.<variable>}
```

For example, if you have a **system variable** `MYPATH=C:\MyPath`, you can use a **Bamboo system variable** `system.MYPATH` which will inherit the same value as the system variable.

ℹ️ In older Bamboo versions using `PATH` in the Environment Variables field (of a Script task) doesn’t set the windows PATH variable, whereas using `Path` sets Path and PATH in cmd shell.

### Using variables in bash

Bamboo variables are exported as bash shell variables. All full stops (periods) are converted to underscores. For example, the variable `bamboo.my.variable` is `@bamboo_my_variable` in bash. This is related to File Script tasks (not Inline Script tasks).

### Jira applications variables

Note that these variables can be accessed from a Bamboo build only when that build was triggered by releasing a version in Jira Software Server.

<table>
<thead>
<tr>
<th>Jira variable</th>
<th>Description</th>
</tr>
</thead>
</table>
Documentation for Bamboo 6.7

Examples

Maven examples

For example, you may want your Maven 2 version to be determined by Bamboo. In Maven 2 `pom.xml` you may have:

```xml
...<groupId>com.atlassian.boo</groupId>
<artifactId>boo-test</artifactId>
<packaging>jar</packaging>
<version>1.1.1${bambooBuildNumber}-SNAPSHOT</version>
...
```

You can then specify the following in the **Goal** field of your build plan:

```
clean package -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Maven build to use. The command will then produce a jar that looks like this: `boo-test-1.1.1102-SNAPSHOT.jar`.

Ant examples

You can then specify the following in the **Target** field of your build plan:

```
-f build.xml -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Ant build to use.

Specifying capabilities as variables

You can also specify a capability to be used in a similar way to a global variable.

The format of the capability should be as follows:

```
${bamboo.capability.<capability_key>}
```

For example,
Custom

${bamboo.capability.<capability_key>}

JDK

${bamboo.capability.system.jdk.<jdk_label>}

Builder

${bamboo.capability.system.builder.<builder_type>.<builder_label>}
e.g. ${bamboo.capability.system.builder.maven.Maven1}

Perforce

${bamboo.capability.system.p4Executable}

If you click on a capability, the specific capability key will be contained in the URL.

Please note, the space characters in the URL will be replaced with '+' characters. We recommend that you do not use capability labels with space characters, if you wish to use them as variables. A possible solution for space characters is to format them with '${}' symbols, however, this does not work in all cases.

Using capabilities

Global and Build-Specific Variables can be used in a specific fields of your build plan, as specified above. For capabilities,

- **System Capabilities** are available to all of these fields, (i.e. global and build-specific).
- **Agent Capabilities** (i.e. agent-specific and shared/server capabilities) are available only to the build-specific fields. (i.e. not available to Repository URL, CVS Root or Branch name.)

For example,

If you wanted to specify a system variable, but have it set to different values on each agent, do the following:

- Set the following as a system environment variable field on the Builder tab:

  ${bamboo.capability.thatsystemvariable}

- Specify the system environment variable as a custom capability on each of your agents, and set to the capability to the different values, as desired.

Deprecated variables

The following variables are deprecated and are subject for removal in future Bamboo releases:

<table>
<thead>
<tr>
<th>Generic repository variables</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.repository.revision.number</td>
<td>The revision number.</td>
</tr>
<tr>
<td>bamboo.repository.branch.name</td>
<td>The repository branch name (for Bamboo version 4.2 or later).</td>
</tr>
<tr>
<td>bamboo.repository.previous.revision.number</td>
<td>The previous revision number (might not exist, for example for the initial build).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Subversion</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.custom.svn.revision.number</td>
<td>The revision number.</td>
</tr>
</tbody>
</table>
### Defining global variables

When configuring a plan, you may want to specify variables to be used in the build process. For details on how variables are used, see Bamboo variables.

Global variables are one type of variable that is available to you. Global variables are defined across your entire Bamboo instance, and have the same value for every plan that is built by Bamboo. If you want to define a variable for a specific plan rather than across all plans, define a plan variable as described in Defining plan variables.

Global variables can be accessed by using `${bamboo.globalVarName}`. Global variables can also be overridden at runtime when running a manual build. For more information, see Running a plan build manually.

#### Related pages:
- Bamboo variables
- Defining plan variables
- Running a plan build manually

#### To access the global variables page:

1. Click the 
   ![icon] icon and select **Global Variables**.
2. Add, update or delete the global variables, as desired:
   - Click **Add** to add a new variable once you have entered the key and value for it.
   - Updates to existing rows will be saved as you move between cells in the table.
   - Click the cross icon to delete a variable. Bamboo will ask you to confirm its deletion.

---

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.custom.svn.lastchange.revision.number</td>
<td>The last changed revision number.</td>
</tr>

</tr>
</tbody>
</table>

**Screenshot:** Global variables
Defining plan variables

When configuring a plan, you may want to specify variables to be used in the build process. For details on how variables are used, see **Bamboo variables**.

**Plan variables** are one type of variable that is available to you. A plan variable is defined for one specific plan, and has the same value every time that plan is built. If you want to define a variable across all plans rather than a single plan, define a global variable as described in **Defining global variables**.

Plan variables can be accessed by using `${bamboo.varName}`. Plan variables can also be overridden at runtime when running a manual build. For more information, see **Running a plan build manually**.

### Related pages:
- Bamboo variables
- Defining global variables
- Running a plan build manually

Before you begin:

- Note that plan variables override global variables with the same name.

#### To define a plan variable:

1. Click Dashboard, then the All Plans tab, then the name of the plan in the list, to get to the plan you want to edit.
2. Choose Actions > Configure Plan.
3. Click the Variables tab.
4. Add, update or delete plan variables, as desired:
   - Click Add to add a new variable once you have entered the key and value for it.
   - Updates to existing rows will be saved as you move between cells in the table.
   - Click the cross icon to delete a variable. Bamboo will ask you to confirm deletion.

**Screenshot: Adding a plan variable**
Passing Bamboo variables to a build script

Bamboo global and build specific variables can be referred to in build scripts or maven pom.xml. Bamboo variables are not directly available in the builder execution context however. They can be passed as parameters to the builder.

**Maven**

For example, you may want your Maven 2 version to be determined by Bamboo. In Maven 2 pom.xml you may have:

```xml
... 
<groupId>com.atlassian.boo</groupId> 
<artifactId>boo-test</artifactId> 
<packaging>jar</packaging> 
<version>1.1.${bambooBuildNumber}-SNAPSHOT</version> 
... 
```

You can then specify the following in the **Goal** field of your build plan:

```text
clean package -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Maven build to use. The command will then produce a jar that looks like this: `boo-test-1.1.1102-SNAPSHOT.jar`.

**Ant**

You can pass Bamboo variables as ant parameters along with ant targets like:

```text
clean test -Dbuild.key=${bamboo.buildKey}
```

In your ant build script just refer to this variable:

```text
... 
<echo message="bamboo.buildKey = ${build.key}"/> 
... 
```

**Bamboo variables v6.1**

Variables can be used to make values available when building plans in Bamboo.

- **Build-specific variables** are evaluated by Bamboo dynamically at build time. The source of a build-specific variable can either be a Bamboo property or one of the default plugins (assuming it is enabled).
- **Deployment variables** are available when deploying a project.
- **System variables** also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- **Global variables** are defined across your entire Bamboo instance, and have the same (static) value for every plan that is built by Bamboo. See **Defining global variables**.
• **Plan variables** are similar to global variables, but are defined for specific plans. Plan variables override global variables with the same name. You can also override a plan variable for a build if you trigger the build manually. See Defining plan variables.

**Using variables**

Variables can be used in all fields of a task or deployment, with the exception of password fields. Use the following format when referencing a variable:

```${bamboo.variableName}```

You can override a plan variable for a build, if you trigger the build manually. See Triggering a plan build manually.

⚠️ You cannot reference a variable from another variable in Bamboo, i.e. "double de-referencing". See this knowledge base article for more information.

**Defining custom variables**

You can define your own custom variables, using a similar format to that above, however you cannot create a variable name that is already in use by Bamboo.

For information on how to define your own variables in Bamboo, see:

- Defining global variables
- Defining plan variables
- Defining deployment environment variables

**On this page:**

- Using variables
- Defining custom variables
- Build-specific variables

**Related pages:**

- Running a plan build manually
- Defining deployment environment variables
- Configuring plugins

**Build-specific variables**

The following build-specific variables are available by default:

- **System variables** apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- In the variable names from the table, `<position>` is an optional parameter that specifies the position of the repository in the plan's repository list. If omitted, the first repository in the list is used.
- Third-party repository plugins can expose their own variables.

<table>
<thead>
<tr>
<th>Build-specific variable</th>

<td>The name of the release that is being replaced (if available). Either .release or .version can be used - both return the name of the release being replaced.</td>
</tr>
<tr>
<td>bambo.resultsUrl</td>
<td>The URL to the screen in Bamboo that dispays build results.</td>
</tr>
</tbody>
</table>

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
You can generate variables of your own, using a similar format, however you cannot create a variable that is already in use by Bamboo. See [Defining deployment environment variables](#) for more information.

### Releases variables

Bamboo makes the following types of variables available for deployment releases:

- Snapshots of values for **global variables**.
- Snapshots of values for **plan variables**.
- Snapshots of values of repository variables.
- The autogenerated release variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildNumber</td>
<td>The build result from which the release is created.</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The key of the build result from which the release is created e.g. KUNG-FOO-JOB1-35</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the plan related to the release e.g. KUNG-FOO</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The name of the plan related to the release e.g. Kung-Foo</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the plan related to the release (without project part), e.g. MAIN</td>
</tr>
<tr>
<td>bamboo.shortPlanName</td>
<td>The plan’s name without project part, e.g. Some plan name</td>
</tr>
</tbody>
</table>

Note that several of the variables in the above table are actually those associated with the build plan.

### System variables

The usage format for all system variables is:

```bash
${system.<variable>}
```

For example, if you have a system variable `MYPATH=C:\MyPath;` you can use a Bamboo system variable `system.MYPATH` which will inherit the same value as the system variable.

**Important:** In older Bamboo versions using ‘PATH’ in the Environment Variables field (of a Script task) doesn’t set the windows PATH variable, whereas using ‘Path’ sets Path and PATH in cmd shell.

#### Using variables in bash

Bamboo variables are exported as bash shell variables. All full stops (periods) are converted to underscores. For example, the variable `bamboo.my.variable` is `@bamboo_my_variable` in bash. This is related to File Script tasks (not Inline Script tasks).

### Jira applications variables

Note that these variables can be accessed from a Bamboo build only when that build was triggered by releasing a version in Jira Software Server.

<table>
<thead>
<tr>
<th>Jira variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$[bamboo.jira.baseUrl]</td>
<td>The URL of your Jira application server.</td>
</tr>
<tr>
<td>$[bamboo.jira.projectKey]</td>
<td>The key of the triggering Jira application project.</td>
</tr>
<tr>
<td>$[bamboo.jira.projectName]</td>
<td>The name of the triggering Jira application project.</td>
</tr>
<tr>
<td>$[bamboo.jira.version]</td>
<td>The release version of the triggering Jira application project.</td>
</tr>
<tr>
<td>$[bamboo.jira.username]</td>
<td>The username of the user who triggered the release build.</td>
</tr>
</tbody>
</table>

### Examples

**Maven examples**
For example, you may want your Maven 2 version to be determined by Bamboo. In Maven 2 `pom.xml` you may have:

```xml
... 
<groupId>com.atlassian.boo</groupId>
<artifactId>boo-test</artifactId>
<packaging>jar</packaging>
<version>1.1.1${bambooBuildNumber}-SNAPSHOT</version>
... 
```

You can then specify the following in the **Goal** field of your build plan:

```shell
clean package -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Maven build to use. The command will then produce a jar that looks like this: `boo-test-1.1.1102-SNAPSHOT.jar`.

**Ant examples**

You can then specify the following in the **Target** field of your build plan:

```shell
-f build.xml -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Ant build to use.

**Specifying capabilities as variables**

You can also specify a capability to be used in a similar way to a global variable.

The format of the capability should be as follows:

```shell
${bamboo.capability.<capability_key>}
```

For example,
If you click on a capability, the specific capability key will be contained in the URL.

Please note, the space characters in the URL will be replaced with '+' characters. We recommend that you do not use capability labels with space characters, if you wish to use them as variables. A possible solution for space characters is to format them with '${}' symbols, however, this does not work in all cases.

Using capabilities

Global and Build-Specific Variables can be used in a specific fields of your build plan, as specified above. For capabilities,

- **System Capabilities** are available to all of these fields, (i.e. global and build-specific).
- **Agent Capabilities** (i.e. agent-specific and shared/server capabilities) are available only to the build-specific fields. (i.e. not available to Repository URL, CVS Root or Branch name.)

For example,

If you wanted to specify a system variable, but have it set to different values on each agent, do the following:

- Set the following as a system environment variable field on the **Builder** tab:

  ```
  ${bamboo.capability.thatsystemvariable}
  ```

- Specify the system environment variable as a custom capability on each of your agents, and set to the capability to the different values, as desired.

**Deprecated variables**

The following variables are deprecated and are subject for removal in future Bamboo releases:

<table>
<thead>
<tr>
<th>Generic repository variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.repository.revision.number</td>
<td>The revision number.</td>
</tr>
<tr>
<td>bamboo.repository.branch.name</td>
<td>The repository branch name (for Bamboo version 4.2 or later).</td>
</tr>
<tr>
<td>bamboo.repository.previous.revision.number</td>
<td>The previous revision number (might not exist, for example for the initial build).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Subversion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.custom.svn.revision.number</td>
<td>The revision number.</td>
</tr>
<tr>
<td>bamboo.custom.svn.lastchange.revision.number</td>
<td>The last changed revision number.</td>
</tr>
</tbody>
</table>
### .Bamboo variables v5.14

Variables can be used to make values available when building plans in Bamboo.

- **Build-specific variables** are evaluated by Bamboo dynamically at build time. The source of a build-specific variable can either be a Bamboo property or one of the default plugins (assuming it is enabled).
- **Deployment variables** are available when deploying a project.
- **System variables** also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- **Global variables** are defined across your entire Bamboo instance, and have the same (static) value for every plan that is built by Bamboo. See [Defining global variables](#).
- **Plan variables** are similar to global variables, but are defined for specific plans. Plan variables override global variables with the same name. You can also override a plan variable for a build if you trigger the build manually. See [Defining plan variables](#).

### Using variables

Variables can be used in all fields of a task or deployment, with the exception of password fields. Use the following format when referencing a variable:

```
${bamboo.variableName}
```

You can override a plan variable for a build, if you trigger the build manually. See [Triggering a plan build manually](#).

⚠️ You cannot reference a variable from another variable in Bamboo, i.e. “double de-referencing”. See [this knowledge base article](#) for more information.

### Defining custom variables

You can define your own custom variables, using a similar format to that above, however you cannot create a variable name that is already in use by Bamboo.

For information on how to define your own variables in Bamboo, see:

- [Defining global variables](#)

<table>
<thead>
<tr>
<th>Bamboo variable name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bamboo.custom.svn.username</code></td>
<td>User name used for repository authentication.</td>
</tr>
<tr>
<td><code>bamboo.repository.svn.repositoryUrl</code></td>
<td>The repository URL.</td>
</tr>
<tr>
<td><code>bamboo.planRepository.&lt;position&gt;.revision.number</code></td>
<td>The revision number.</td>
</tr>
<tr>
<td><code>bamboo.planRepository.&lt;position&gt;.lastchange.revision.number</code></td>
<td>The last-changed revision number.</td>
</tr>
<tr>
<td><strong>CVS</strong></td>
<td></td>
</tr>
<tr>
<td><code>bamboo.custom.cvs.last.update.time</code></td>
<td>The last updated timestamp.</td>
</tr>
<tr>
<td><code>bamboo.custom.cvs.last.update.time.label</code></td>
<td>The last updated timestamp to be used as a label for post build result labeling. The spaces in the CVS version string are replaced with <code>_</code>.</td>
</tr>
<tr>
<td><strong>Perforce</strong></td>
<td></td>
</tr>
<tr>
<td><code>bamboo.custom.p4.revision.number</code></td>
<td>The change set number.</td>
</tr>
<tr>
<td><code>bamboo.custom.p4.username</code></td>
<td>User name used for repository authentication.</td>
</tr>
<tr>
<td><code>bamboo.custom.p4.port</code></td>
<td>Port used for repository communication.</td>
</tr>
<tr>
<td><code>bamboo.custom.p4.client</code></td>
<td>Client used for repository communication.</td>
</tr>
<tr>
<td><strong>Git</strong></td>
<td></td>
</tr>
<tr>
<td><code>bamboo.repository.git.branch</code></td>
<td>The branch.</td>
</tr>
<tr>
<td><code>bamboo.repository.git.repositoryUrl</code></td>
<td>The repository URL.</td>
</tr>
<tr>
<td><strong>Mercurial</strong></td>
<td></td>
</tr>
<tr>
<td><code>bamboo.repository.hg.repositoryUrl</code></td>
<td>The repository URL.</td>
</tr>
<tr>
<td><code>bamboo.repository.hg.branch</code></td>
<td>The branch.</td>
</tr>
<tr>
<td><code>bamboo.repository.hg.username</code></td>
<td>User name, used for repository authentication.</td>
</tr>
</tbody>
</table>
Build-specific variables

The following build-specific variables are available by default:

- **System variables** apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- In the variable names from the table, `<position>` is an optional parameter that specifies the position of the repository in the plan's repository list. If omitted, the first repository in the list is used.
- Third-party repository plugins can expose their own variables.

<table>
<thead>
<tr>
<th>Build-specific variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildKey</td>
<td>The job key for the current job, in the form PROJECT-PLAN-JOB, e.g. BAM–MAIN–JOBX</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the current plan, in the form PROJECT-PLAN, e.g. BAM–MAIN</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the current plan (without project part), e.g. MAIN</td>
</tr>
<tr>
<td>bamboo.shortJobKey</td>
<td>The short key of the current job (without project and plan parts), e.g. JOBX</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The result key when this job executes, in the form PROJECT-PLAN-JOB-BUILD e.g. BAM–BOO–JOB1–8, where '8' is the build number. For deployment projects this variable will not have the JOB component e.g. PROJ–TP–6.</td>
</tr>
<tr>
<td>bamboo.buildResultsUrl or bamboo.resultsUrl</td>
<td>The URL of the result in Bamboo once the job has finished executing.</td>
</tr>
<tr>
<td>bamboo.buildNumber</td>
<td>The Bamboo build number, e.g. 123</td>
</tr>
<tr>
<td>bamboo.buildPlanName</td>
<td>The Bamboo job name e.g. Some Project name – Some plan name – Some job name</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The current plan's name e.g. Some project name – Some plan name</td>
</tr>
<tr>
<td>bamboo.shortPlanName</td>
<td>The current plan’s name without project part, e.g. Some plan name</td>
</tr>
<tr>
<td>bamboo.shortJobName</td>
<td>The current job's name without project and plan parts, e.g. Some job name</td>
</tr>
<tr>
<td>bamboo.buildTime Stamp</td>
<td>The time when build was started in ISO 8601 format e.g. 2010-01-01T00:00:00.000+01:00</td>
</tr>
<tr>
<td>Variable Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>bamboo.agentId</td>
<td>The ID of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td>bamboo.agentWorkingDirectory</td>
<td>The path to the working directory on the agent, for example <code>&lt;HOME&gt;/xml-data/build-dir</code>. The agent working directory is not the same as the build working directory described below.</td>
</tr>
<tr>
<td>bamboo.build.working.directory</td>
<td>The working directory on which the build is being executed, for example <code>&lt;HOME&gt;/xml-data/build-dir/AV-AVT-JOB1</code>.</td>
</tr>
<tr>
<td>bamboo.ManualBuildTriggerReason.userName</td>
<td>The user who triggered the manual build.</td>
</tr>
</tbody>
</table>

**Generic repository variables**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.branchName</td>
<td>The name of the branch in the repository (depends on availability from the VCS used) e.g. <code>default</code>.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.name</td>
<td>The name of the repository, as shown in the repository for the plan e.g. <code>Mercurial</code>.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.revision</td>
<td>The revision used to build this release. Format depends on the VCS used.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.previousRevision</td>
<td>The previous revision number (this might not exist, for example for the initial build).</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.type</td>
<td>The type of the repository, as defined by a repository plugin e.g. <code>hg</code>, <code>svn</code>, <code>git</code>.</td>
</tr>
</tbody>
</table>

**Subversion**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.username</td>
<td>User name, used for repository authentication.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
</tbody>
</table>

**CVS**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.last.update.time</td>
<td>The last updated timestamp.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.last.update.time.label</td>
<td>The last updated timestamp to be used as a label for post build result labeling. The spaces in the cvs version string are replaced with <code>_</code>.</td>
</tr>
</tbody>
</table>

**Perforce**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.revision.number</td>
<td>The change set number.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.username</td>
<td>User name, used for repository authentication.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.port</td>
<td>Port used for repository communication.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.client</td>
<td>Client used for repository communication.</td>
</tr>
</tbody>
</table>

**Git**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.branch</td>
<td>The branch.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
</tbody>
</table>

**Mercurial**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.branch</td>
<td>The branch.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.username</td>
<td>User name, used for repository authentication.</td>
</tr>
</tbody>
</table>

- System variables also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- In the variable names from the table above, `<position>` is an optional parameter that specifies the position of the repository in the plan's repository list. If omitted, the first repository in the list is used.
- Third-party repository plugins can expose their own variables.

**Build dependency variables**
The following build dependency variables are also available:

<table>
<thead>
<tr>
<th>Build-specific variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.dependency.parent.#</td>
<td>Allows a child build to query the build key of the triggering parent build, where # represents the position in the build tree - 0 at the top, 1 following, and so on. The ${bamboo.dependency.parent.0} variable can be viewed in the child plan's metadata tab.</td>
</tr>
<tr>
<td>bamboo.dependency.parent.total</td>
<td>The total # of parent builds.</td>
</tr>
</tbody>
</table>

**Deployment variables**

Bamboo manages a number of standard reserved variables that are available when deploying a project.

Variables later in the following list override the previous ones in case of repeating names:

- global variables
- release variables as defined below
- user variables defined at environment level
- the autogenerated variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.agentId</td>
<td>The id of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td>bamboo.agentWorkingDirectory</td>
<td>The path to the working directory on the agent. This is not the same as the Bamboo working directory.</td>
</tr>
<tr>
<td>bamboo.build.working.directory</td>
<td>The path to the working directory for Bamboo. This is used by both the build plan and the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.environment</td>
<td>The name of the environment that the release is to be deployed to.</td>
</tr>
<tr>
<td>bamboo.deploy.project</td>
<td>The name of the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.rollback</td>
<td>True if the release being deployed is older than the release being replaced.</td>
</tr>
<tr>
<td>bamboo.deploy.release</td>
<td>The name of the release that is being deployed. Either .release or .version can be used - both return the name of the release being deployed.</td>
</tr>
<tr>
<td>bamboo.deploy.version</td>
<td>The name of the version that is being deployed. Either .release or .version can be used - both return the name of the release being deployed.</td>
</tr>
<tr>
<td>bamboo.deploy.release.previous</td>
<td>The name of the release that is being replaced (if available). Either .release or .version can be used - both return the name of the release being replaced.</td>
</tr>
<tr>
<td>bamboo.deploy.version.previous</td>
<td>The name of the version that is being replaced (if available). Either .release or .version can be used - both return the name of the release being replaced.</td>
</tr>
<tr>
<td>bamboo.resultsUrl</td>
<td>The URL to the screen in Bamboo that displays build results.</td>
</tr>
</tbody>
</table>

You can generate variables of your own, using a similar format, however you cannot create a variable that is already in use by Bamboo. See Defining deployment environment variables for more information.

**Releases variables**

Bamboo makes the following types of variables available for deployment releases:

- Snapshots of values for global variables.
- Snapshots of values for plan variables.
- Snapshots of values of repository variables.
- The autogenerated release variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildNumber</td>
<td>The build result from which the release is created.</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The key of the build result from which the release is created e.g. KUNG-FOO-JOB1-35</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the plan related to the release e.g. KUNG-FOO</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The name of the plan related to the release e.g. Kung - Foo</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the plan related to the release (without project part), e.g. MAIN</td>
</tr>
</tbody>
</table>
bamboo.shortPlanName

The plan’s name without project part, e.g. Some plan name

Note that several of the variables in the above table are actually those associated with the build plan.

System variables

The usage format for all system variables is:

```
${system.<variable>}
```

For example, if you have a system variable `MYPATH=C:\MyPath`; you can use a Bamboo system variable `system.MYPATH` which will inherit the same value as the system variable.

In older Bamboo versions using ‘PATH’ in the Environment Variables field (of a Script task) doesn’t set the windows PATH variable, whereas using ‘Path’ sets Path and PATH in cmd shell.

Using variables in bash

Bamboo variables are exported as bash shell variables. All full stops (periods) are converted to underscores. For example, the variable `bamb oo.my.variable` is `$bamboo_my_variable` in bash. This is related to File Script tasks (not Inline Script tasks).

Jira applications variables

Note that these variables can be accessed from a Bamboo build only when that build was triggered by releasing a version in Jira Software Server.

<table>
<thead>
<tr>
<th>Jira variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>${bamboo.jira.baseUrl}</code></td>
<td>The URL of your Jira application server.</td>
</tr>
<tr>
<td><code>${bamboo.jira.projectKey}</code></td>
<td>The key of the triggering Jira application project.</td>
</tr>
<tr>
<td><code>${bamboo.jira.projectName}</code></td>
<td>The name of the triggering Jira application project.</td>
</tr>
<tr>
<td><code>${bamboo.jira.version}</code></td>
<td>The release version of the triggering Jira application project.</td>
</tr>
<tr>
<td><code>${bamboo.jira.username}</code></td>
<td>The username of the user who triggered the release build.</td>
</tr>
</tbody>
</table>

Examples

**Maven examples**

For example, you may want your Maven 2 version to be determined by Bamboo. In Maven 2 `pom.xml` you may have:

```xml
...  
<groupId>com.atlassian.boo</groupId>  
<artifactId>boo-test</artifactId>  
<packaging>jar</packaging>  
<version>1.1.`${bambooBuildNumber}`-SNAPSHOT</version>  
...  
```

You can then specify the following in the **Goal** field of your build plan:

```
clean package -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Maven build to use. The command will then produce a jar that looks like this: `boo-test-1.1.1102-SNAPSHOT.jar`.

**Ant examples**

You can then specify the following in the **Target** field of your build plan:
When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Ant build to use.

Specifying capabilities as variables

You can also specify a capability to be used in a similar way to a global variable.

The format of the capability should be as follows:

```
${bamboo.capability.<capability_key>}
```

For example,

- **Custom**
  ```
  ${bamboo.capability.<capability_key>}
  ```

- **JDK**
  ```
  ${bamboo.capability.system.jdk.<jdk_label>}
  ```

- **Builder**
  ```
  ${bamboo.capability.system.builder.<builder_type>.<builder_label>}
  e.g. ${bamboo.capability.system.builder.maven.Maven1}
  ```

- **Perforce**
  ```
  ${bamboo.capability.system.p4Executable}
  ```

If you click on a capability, the specific capability key will be contained in the URL.

Please note, the space characters in the URL will be replaced with `+' characters. We recommend that you do not use capability labels with space characters, if you wish to use them as variables. A possible solution for space characters is to format them with `{}' symbols, however, this does not work in all cases.

Using capabilities

Global and Build-Specific Variables can be used in a specific fields of your build plan, as specified above. For capabilities,

- **System Capabilities** are available to all of these fields, (i.e. global and build-specific).
- **Agent Capabilities** (i.e. agent-specific and shared/server capabilities) are available only to the build-specific fields. (i.e. not available to Repository URL, CVS Root or Branch name.)

For example,
If you wanted to specify a system variable, but have it set to different values on each agent, do the following:

- Set the following as a system environment variable field on the **Builder** tab:

  ```
  ${bamboo.capability.thatSystemVariable}
  ```

- Specify the system environment variable as a custom capability on each of your agents, and set to the capability to the different values, as desired.

## Deprecated variables

The following variables are deprecated and are subject for removal in future Bamboo releases:

<table>
<thead>
<tr>
<th>Generic repository variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bamboo.repository.revision.number</code></td>
<td>The revision number.</td>
</tr>
<tr>
<td><code>bamboo.repository.branch.name</code></td>
<td>The repository branch name (for Bamboo version 4.2 or later).</td>
</tr>
<tr>
<td><code>bamboo.repository.previous.revision.number</code></td>
<td>The previous revision number (might not exist, for example for the initial build).</td>
</tr>
</tbody>
</table>

### Subversion

<table>
<thead>
<tr>
<th>Subversion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bamboo.custom.svn.revision.number</code></td>
<td>The revision number.</td>
</tr>
<tr>
<td><code>bamboo.custom.svn.lastchange.revision.number</code></td>
<td>The last changed revision number.</td>
</tr>
<tr>
<td><code>bamboo.custom.svn.username</code></td>
<td>User name used for repository authentication.</td>
</tr>
<tr>
<td><code>bamboo.repository.svn.repositoryUrl</code></td>
<td>The repository URL.</td>
</tr>
<tr>
<td><code>bamboo.planRepository.&lt;position&gt;.revision.number</code></td>
<td>The revision number.</td>
</tr>
<tr>
<td><code>bamboo.planRepository.&lt;position&gt;.lastchange.revision.number</code></td>
<td>The last-changed revision number.</td>
</tr>
</tbody>
</table>

### CVS

<table>
<thead>
<tr>
<th>CVS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bamboo.custom.cvs.last.update.time</code></td>
<td>The last updated timestamp.</td>
</tr>
<tr>
<td><code>bamboo.custom.cvs.last.update.time.label</code></td>
<td>The last updated timestamp to be used as a label for post build result labeling. The spaces in the CVS version string are replaced with <code>_</code>.</td>
</tr>
</tbody>
</table>

### Perforce

<table>
<thead>
<tr>
<th>Perforce</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bamboo.custom.p4.revision.number</code></td>
<td>The change set number.</td>
</tr>
<tr>
<td><code>bamboo.custom.p4.username</code></td>
<td>User name used for repository authentication.</td>
</tr>
<tr>
<td><code>bamboo.custom.p4.port</code></td>
<td>Port used for repository communication.</td>
</tr>
<tr>
<td><code>bamboo.custom.p4.client</code></td>
<td>Client used for repository communication.</td>
</tr>
</tbody>
</table>

### Git

<table>
<thead>
<tr>
<th>Git</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bamboo.repository.git.branch</code></td>
<td>The branch.</td>
</tr>
<tr>
<td><code>bamboo.repository.git.repositoryUrl</code></td>
<td>The repository URL.</td>
</tr>
</tbody>
</table>

### Mercurial

<table>
<thead>
<tr>
<th>Mercurial</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bamboo.repository.hg.repositoryUrl</code></td>
<td>The repository URL.</td>
</tr>
<tr>
<td><code>bamboo.repository.hg.branch</code></td>
<td>The branch.</td>
</tr>
<tr>
<td><code>bamboo.repository.hg.username</code></td>
<td>User name, used for repository authentication.</td>
</tr>
</tbody>
</table>

## .Bamboo variables v6.0

Variables can be used to make values available when building plans in Bamboo.

- **Build-specific variables** are evaluated by Bamboo dynamically at build time. The source of a build-specific variable can either be a Bamboo property or one of the default plugins (assuming it is enabled).
- **Deployment variables** are available when deploying a project.
• **System variables** also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
• **Global variables** are defined across your entire Bamboo instance, and have the same (static) value for every plan that is built by Bamboo. See Defining global variables.
• **Plan variables** are similar to global variables, but are defined for specific plans. Plan variables override global variables with the same name. You can also override a plan variable for a build if you trigger the build manually. See Defining plan variables.

Using variables

Variables can be used in all fields of a task or deployment, with the exception of password fields. Use the following format when referencing a variable:

```
${bamboo.variableName}
```

You can override a plan variable for a build, if you trigger the build manually. See Triggering a plan build manually.

⚠️ You cannot reference a variable from another variable in Bamboo, i.e. "double de-referencing". See this knowledge base article for more information.

Defining custom variables

You can define your own custom variables, using a similar format to that above, however you cannot create a variable name that is already in use by Bamboo.

For information on how to define your own variables in Bamboo, see:

• Defining global variables
• Defining plan variables
• Defining deployment environment variables

The following build-specific variables are available by default:

• **System variables** apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
  • In the variable names from the table, `<position>` is an optional parameter that specifies the position of the repository in the plan's repository list. If omitted, the first repository in the list is used.
  • Third-party repository plugins can expose their own variables.

<table>
<thead>
<tr>
<th>Build-specific variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildKey</td>
<td>The job key for the current job, in the form PROJECT-PLAN-JOB, e.g. BAM-MAIN-JOBX</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the current plan, in the form PROJECT-PLAN, e.g. BAM-MAIN</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the current plan (without project part), e.g. MAIN</td>
</tr>
<tr>
