<td>bamboo.shortJobKey</td>
<td>The short key of the current job (without project and plan parts), e.g. JOBX</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The result key when this job executes, in the form PROJECT-PLAN-JOB-BUILD e.g. BAM-BOO-JOB1-8, where '8' is the build number. For deployment projects this variable will not have the JOB component e.g. PROJ-TP-6.</td>
</tr>
<tr>
<td>bamboo.buildResultsUrl or bamboo.resultsUrl</td>
<td>The URL of the result in Bamboo once the job has finished executing.</td>
</tr>
<tr>
<td>bamboo.buildNumber</td>
<td>The Bamboo build number, e.g. 123</td>
</tr>
<tr>
<td>bamboo.buildPlanName</td>
<td>The Bamboo job name e.g. Some Project name - Some plan name - Some job name</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The current plan's name e.g. Some project name - Some plan name</td>
</tr>
<tr>
<td>bamboo.shortPlanName</td>
<td>The current plan's name without project part, e.g. Some plan name</td>
</tr>
<tr>
<td>bamboo.shortJobName</td>
<td>The current job's name without project and plan parts, e.g. Some job name</td>
</tr>
<tr>
<td>bamboo.buildTimeStamp</td>
<td>The time when build was started in ISO 8601 format e.g. 2010-01-01T01:00:00.000+01:00</td>
</tr>
<tr>
<td>bamboo.agentId</td>
<td>The ID of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td>bamboo.agentWorkingDirectory</td>
<td>The path to the working directory on the agent, for example &lt;HOME&gt;/xml-data/build-dir. The agent working directory is not the same as the build working directory described below.</td>
</tr>
<tr>
<td>bamboo.build.working.directory</td>
<td>The working directory on which the build is being executed, for example &lt;HOME&gt;/xml-data/build-dir/AV-AVT-JOB1.</td>
</tr>
<tr>
<td>bamboo.ManualBuildTriggerReason.userName</td>
<td>The user who triggered the manual build.</td>
</tr>
</tbody>
</table>

**Generic repository variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.branchName</td>
<td>The name of the branch in the repository (depends on availability from the VCS used) e.g. default</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.name</td>
<td>The name of of the repository, as shown in the repository for the plan e.g. Mercurial</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.revision</td>
<td>The revision use to build this release. Format depends on the VCS used.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.previousRevision</td>
<td>The previous revision number (this might not exist, for example for the initial build).</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.type</td>
<td>The type of the repository, as defined by a repository plugin e.g. hg, svn, git</td>
</tr>
<tr>
<td>branch.DisplayName</td>
<td>The name of the branch displayed in the branch details section.</td>
</tr>
</tbody>
</table>

**Subversion**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.username</td>
<td>User name, used for repository authentication.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
</tbody>
</table>

**CVS**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.last.update.time</td>
<td>The last updated timestamp.</td>
</tr>
</tbody>
</table>
bamboo.planRepository.<position>.last.update.time.label

The last updated timestamp to be used as a label for post build result labeling. The spaces in the cvs version string are replaced with '_'.

Perforce

bamboo.planRepository.<position>.revision.number

The change set number.

bamboo.planRepository.<position>.username

User name, used for repository authentication.

bamboo.planRepository.<position>.port

Port used for repository communication.

bamboo.planRepository.<position>.client

Client used for repository communication.

Git

bamboo.planRepository.<position>.branch

The branch

bamboo.planRepository.<position>.repositoryUrl

The repository URL

Mercurial

bamboo.planRepository.<position>.repositoryUrl

The repository URL

bamboo.planRepository.<position>.branch

The branch

bamboo.planRepository.<position>.username

User name, used for repository authentication.

• **System variables** also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.

• In the variable names from the table above, `<position>` is an optional parameter that specifies the position of the repository in the plan’s repository list. If omitted, the first repository in the list is used.

• Third-party repository plugins can expose their own variables.

**Build dependency variables**

The following build dependency variables are also available:

<table>
<thead>
<tr>
<th>Build-specific variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.dependency.parent.#</td>
<td>Allows a child build to query the build key of the triggering parent build, where # represents the position in the build tree - 0 at the top, 1 the following, and so on. The ${bamboo.dependency.parent.0} variable can be viewed in the child plan’s metadata tab.</td>
</tr>
<tr>
<td>bamboo.dependency.parent.total</td>
<td>The total # of parent builds.</td>
</tr>
</tbody>
</table>

**Deployment variables**

Bamboo manages a number of standard reserved variables that are available when deploying a project.

Variables later in the following list override the previous ones in case of repeating names:

• global variables
• release variables as defined below
• user variables defined at environment level
• the autogenerated variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.agentId</td>
<td>The id of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td>bamboo.agentWorkingDirectory</td>
<td>The path to the working directory on the agent. This is not the same as the Bamboo working directory.</td>
</tr>
<tr>
<td>bamboo.build.working.directory</td>
<td>The path to the working directory for Bamboo. This is used by both the build plan and the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.environment</td>
<td>The name of the environment that the release is to be deployed to.</td>
</tr>
<tr>
<td>bamboo.deploy.project</td>
<td>The name of the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.rollback</td>
<td>True if the release being deployed is older than the release being replaced.</td>
</tr>
</tbody>
</table>
Releases variables

Bamboo makes the following types of variables available for deployment releases:

- Snapshots of values for global variables.
- Snapshots of values for plan variables.
- Snapshots of values of repository variables.
- The autogenerated release variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildNumber</td>
<td>The build result from which the release is created.</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The key of the build result from which the release is created e.g. KUNG-FOO-JOB1-35</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the plan related to the release e.g. KUNG-FOO</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The name of the plan related to the release e.g. Kung - Foo</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the plan related to the release (without project part), e.g. MAIN</td>
</tr>
<tr>
<td>bamboo.shortPlanName</td>
<td>The plan’s name without project part, e.g. Some plan name</td>
</tr>
</tbody>
</table>

Note that several of the variables in the above table are actually those associated with the build plan.

System variables

The usage format for all system variables is:

```
${system.<variable>}
```

For example, if you have a `system variable` MYPATH=C:\MyPath; you can use a Bamboo system variable `system.MYPATH` which will inherit the same value as the system variable.

ℹ️ In older Bamboo versions using 'PATH' in the Environment Variables field (of a Script task) doesn't set the windows PATH variable, whereas using 'Path' sets Path and PATH in cmd shell.

Using variables in bash

Bamboo variables are exported as bash shell variables. All full stops (periods) are converted to underscores. For example, the variable bamboo.my.variable is ${bamboo_my_variable} in bash. This is related to File Script tasks (not Inline Script tasks).

Jira applications variables

Note that these variables can be accessed from a Bamboo build only when that build was triggered by releasing a version in Jira Software Server.

<table>
<thead>
<tr>
<th>Jira variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>${bamboo.jira.baseUrl}</code></td>
<td>The URL of your Jira application server.</td>
</tr>
<tr>
<td><code>${bamboo.jira.projectKey}</code></td>
<td>The key of the triggering Jira application project.</td>
</tr>
<tr>
<td><code>${bamboo.jira.projectName}</code></td>
<td>The name of the triggering Jira application project.</td>
</tr>
</tbody>
</table>
Examples

**Maven examples**

For example, you may want your Maven 2 version to be determined by Bamboo. In Maven 2 pom.xml you may have:

```xml
... 
<groupId>com.atlassian.boo</groupId>
<artifactId>boo-test</artifactId>
<packaging>jar</packaging>
<version>1.1.${bambooBuildNumber}-SNAPSHOT</version>
...
```

You can then specify the following in the **Goal** field of your build plan:

```
clean package -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Maven build to use. The command will then produce a jar that looks like this: `boo-test-1.1.1102-SNAPSHOT.jar`.

**Ant examples**

You can then specify the following in the **Target** field of your build plan:

```
-f build.xml -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Ant build to use.

**Specifying capabilities as variables**

You can also specify a capability to be used in a similar way to a global variable.

The format of the capability should be as follows:

```
${bamboo.capability.<capability_key>}
```

For example,
• Custom

${bamboo.capability.<capability_key>}

• JDK

${bamboo.capability.system.jdk.<jdk_label>}

e.g. ${bamboo.capability.system.jdk.maven.Maven1}

• Builder

${bamboo.capability.system.builder.<builder_type>.<builder_label>}

• Perforce

${bamboo.capability.system.p4Executable}

If you click on a capability, the specific capability key will be contained in the URL.

Please note, the space characters in the URL will be replaced with '+' characters. We recommend that you do not use capability labels with space characters, if you wish to use them as variables. A possible solution for space characters is to format them with '${}' symbols, however, this does not work in all cases.

Using capabilities

Global and Build-Specific Variables can be used in a specific fields of your build plan, as specified above. For capabilities,

- **System Capabilities** are available to all of these fields, (i.e. global and build-specific).
- **Agent Capabilities** (i.e. agent-specific and shared/server capabilities) are available only to the build-specific fields. (i.e. not available to Repository URL, CVS Root or Branch name.)

For example,

If you wanted to specify a system variable, but have it set to different values on each agent, do the following:

- Set the following as a system environment variable field on the **Builder** tab:

  ${bamboo.capability.thatsystemvariable}

- Specify the system environment variable as a custom capability on each of your agents, and set to the capability to the different values, as desired.

Deprecated variables

The following variables are deprecated and are subject for removal in future Bamboo releases:

<table>
<thead>
<tr>
<th>Generic repository variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.repository.revision.number</td>
<td>The revision number.</td>
</tr>
<tr>
<td>bamboo.repository.branch.name</td>
<td>The repository branch name (for Bamboo version 4.2 or later).</td>
</tr>
<tr>
<td>bamboo.repository.previous.revision.number</td>
<td>The previous revision number (might not exist, for example for the initial build).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Subversion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.custom.svn.revision.number</td>
<td>The revision number.</td>
</tr>
<tr>
<td>bamboo.custom.svn.lastchange.revision.number</td>
<td>The last changed revision number.</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>bamboo.custom.svn.username</td>
<td>User name used for repository authentication.</td>
</tr>
<tr>
<td>bamboo.repository.svn.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.revision.number</td>
<td>The revision number.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.lastchange.revision.number</td>
<td>The last-changed revision number.</td>
</tr>
</tbody>
</table>

**CVS**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.custom.cvs.last.update.time</td>
<td>The last updated timestamp.</td>
</tr>
<tr>
<td>bamboo.custom.cvs.last.update.time.label</td>
<td>The last updated timestamp to be used as a label for post build result labeling. The spaces in the CVS version string are replaced with <code>_</code>.</td>
</tr>
</tbody>
</table>

**Perforce**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.custom.p4.revision.number</td>
<td>The change set number.</td>
</tr>
<tr>
<td>bamboo.custom.p4.username</td>
<td>User name used for repository authentication.</td>
</tr>
<tr>
<td>bamboo.custom.p4.port</td>
<td>Port used for repository communication.</td>
</tr>
<tr>
<td>bamboo.custom.p4.client</td>
<td>Client used for repository communication.</td>
</tr>
</tbody>
</table>

**Git**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.repository.git.branch</td>
<td>The branch.</td>
</tr>
<tr>
<td>bamboo.repository.git.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
</tbody>
</table>

**Mercurial**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.repository.hg.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
<tr>
<td>bamboo.repository.hg.branch</td>
<td>The branch.</td>
</tr>
<tr>
<td>bamboo.repository.hg.username</td>
<td>User name, used for repository authentication.</td>
</tr>
</tbody>
</table>

**.Bamboo variables v5.15**

Variables can be used to make values available when building plans in Bamboo.

- **Build-specific variables** are evaluated by Bamboo dynamically at build time. The source of a build-specific variable can either be a Bamboo property or one of the default plugins (assuming it is enabled).
- **Deployment variables** are available when deploying a project.
- **System variables** also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- **Global variables** are defined across your entire Bamboo instance, and have the same (static) value for every plan that is built by Bamboo. See Defining global variables.
- **Plan variables** are similar to global variables, but are defined for specific plans. Plan variables override global variables with the same name. You can also override a plan variable for a build if you trigger the build manually. See Defining plan variables.

**Using variables**

Variables can be used in all fields of a task or deployment, with the exception of password fields. Use the following format when referencing a variable:

```
${bamboo.variableName}
```

You can override a plan variable for a build, if you trigger the build manually. See Triggering a plan build manually.

⚠️ You cannot reference a variable from another variable in Bamboo, i.e. “double de-referencing”. See this knowledge base article for more information.

**Defining custom variables**

You can define your own custom variables, using a similar format to that above, however you cannot create a variable name that is already in use by Bamboo.

For information on how to define your own variables in Bamboo, see:

- Defining global variables
Build-specific variables

The following build-specific variables are available by default:

- **System variables** apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- In the variable names from the table, `<position>` is an optional parameter that specifies the position of the repository in the plan's repository list. If omitted, the first repository in the list is used.
- Third-party repository plugins can expose their own variables.

<table>
<thead>
<tr>
<th>Build-specific variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildKey</td>
<td>The job key for the current job, in the form PROJECT-PLAN-JOB, e.g. BAM-MAIN-JOBX</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the current plan, in the form PROJECT-PLAN, e.g. BAM-MAIN</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the current plan (without project part), e.g. MAIN</td>
</tr>
<tr>
<td>bamboo.shortJobKey</td>
<td>The short key of the current job (without project and plan parts), e.g. JOBX</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The result key when this job executes, in the form PROJECT-PLAN-JOB-BUILD e.g. BAM-BOO-JOB1-8, where '8' is the build number. For deployment projects this variable will not have the JOB component e.g. PROJ-TP-6.</td>
</tr>
<tr>
<td>bamboo.buildResultsUrl or bamboo.resultsUrl</td>
<td>The URL of the result in Bamboo once the job has finished executing.</td>
</tr>
<tr>
<td>bamboo.buildNumber</td>
<td>The Bamboo build number, e.g. 123</td>
</tr>
<tr>
<td>bamboo.buildPlanName</td>
<td>The Bamboo job name e.g. Some Project name - Some plan name - Some job name</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The current plan's name e.g. Some project name - Some plan name</td>
</tr>
<tr>
<td>bamboo.shortPlanName</td>
<td>The current plan's name without project part, e.g. Some plan name</td>
</tr>
<tr>
<td>bamboo.shortJobName</td>
<td>The current job's name without project and plan parts, e.g. Some job name</td>
</tr>
<tr>
<td>bamboo.buildTimeStamp</td>
<td>The time when build was started in ISO 8601 format e.g. 2010-01-01T01:00:00.000+01:00</td>
</tr>
<tr>
<td>Variable Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>bamboo.agentId</code></td>
<td>The ID of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td><code>bamboo.agentWorkingDirectory</code></td>
<td>The path to the working directory on the agent, for example <code>&lt;HOME&gt;/xml-data/build-dir</code>. The agent working directory is not the same as the build working directory described below.</td>
</tr>
<tr>
<td><code>bamboo.build.working.directory</code></td>
<td>The working directory on which the build is being executed, for example <code>&lt;HOME&gt;/xml-data/build-dir/AV-AVT-JOB1</code>.</td>
</tr>
<tr>
<td><code>bamboo.ManualBuildTriggerReason.userName</code></td>
<td>The user who triggered the manual build.</td>
</tr>
</tbody>
</table>

### Generic repository variables

- `bamboo.planRepository.<position>.branchName`: The name of the branch in the repository (depends on availability from the VCS used) e.g. `default`.
- `bamboo.planRepository.<position>.name`: The name of the repository, as shown in the repository for the plan e.g. `Mercurial`.
- `bamboo.planRepository.<position>.revision`: The revision used to build this release. Format depends on the VCS used.
- `bamboo.planRepository.<position>.previousRevision`: The previous revision number (this might not exist, for example for the initial build).
- `bamboo.planRepository.<position>.type`: The type of the repository, as defined by a repository plugin e.g. `hg`, `svn`, `git`.

#### Subversion

- `bamboo.planRepository.<position>.username`: User name, used for repository authentication.
- `bamboo.planRepository.<position>.repositoryUrl`: The repository URL.

#### CVS

- `bamboo.planRepository.<position>.last.update.time`: The last updated timestamp.
- `bamboo.planRepository.<position>.last.update.time.label`: The last updated timestamp to be used as a label for post build result labeling. The spaces in the cvS version string are replaced with `_`.  

#### Perforce

- `bamboo.planRepository.<position>.revision.number`: The change set number.
- `bamboo.planRepository.<position>.username`: User name, used for repository authentication.
- `bamboo.planRepository.<position>.port`: Port used for repository communication.
- `bamboo.planRepository.<position>.client`: Client used for repository communication.

#### Git

- `bamboo.planRepository.<position>.branch`: The branch.
- `bamboo.planRepository.<position>.repositoryUrl`: The repository URL.

#### Mercurial

- `bamboo.planRepository.<position>.repositoryUrl`: The repository URL.
- `bamboo.planRepository.<position>.branch`: The branch.
- `bamboo.planRepository.<position>.username`: User name, used for repository authentication.

- System variables also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- In the variable names from the table above, `<position>` is an optional parameter that specifies the position of the repository in the plan's repository list. If omitted, the first repository in the list is used.
- Third-party repository plugins can expose their own variables.

**Build dependency variables**

Created by Atlassian in 2018. Licensed under a [Creative Commons Attribution 2.5 Australia License](https://creativecommons.org/licenses/by/2.5/au/).
The following build dependency variables are also available:

<table>
<thead>
<tr>
<th>Build-specific variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.dependency.parent.#</td>
<td>Allows a child build to query the build key of the triggering parent build, where # represents the position in the build tree - 0 at the top, 1 the following, and so on. The ${bamboo.dependency.parent.0} variable can be viewed in the child plan's metadata tab.</td>
</tr>
<tr>
<td>bamboo.dependency.parent.total</td>
<td>The total # of parent builds.</td>
</tr>
</tbody>
</table>

**Deployment variables**

Bamboo manages a number of standard reserved variables that are available when deploying a project.

Variables later in the following list override the previous ones in case of repeating names:

- global variables
- release variables as defined below
- user variables defined at environment level
- the autogenerated variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.agentId</td>
<td>The id of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td>bamboo.agentWorkingDirectory</td>
<td>The path to the working directory on the agent. This is not the same as the Bamboo working directory.</td>
</tr>
<tr>
<td>bamboo.build.working.directory</td>
<td>The path to the working directory for Bamboo. This is used by both the build plan and the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.environment</td>
<td>The name of the environment that the release is to be deployed to.</td>
</tr>
<tr>
<td>bamboo.deploy.project</td>
<td>The name of the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.rollback</td>
<td>True if the release being deployed is older than the release being replaced.</td>
</tr>
<tr>
<td>bamboo.deploy.release</td>
<td>The name of the release that is being deployed. Either .release or .version can be used - both return the name of the release being deployed.</td>
</tr>
<tr>
<td>bamboo.deploy.version</td>
<td>The name of the release that is being replaced (if available). Either .release or .version can be used - both return the name of the release being replaced.</td>
</tr>
<tr>
<td>bamboo.resultsUrl</td>
<td>The URL to the screen in Bamboo that displays build results.</td>
</tr>
</tbody>
</table>

You can generate variables of your own, using a similar format, however you cannot create a variable that is already in use by Bamboo. See [Defining deployment environment variables](#) for more information.

**Releases variables**

Bamboo makes the following types of variables available for deployment releases:

- Snapshots of values for global variables.
- Snapshots of values for plan variables.
- Snapshots of values of repository variables.
- The autogenerated release variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildNumber</td>
<td>The build result from which the release is created.</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The key of the build result from which the release is created e.g. KUNG-FOO-JOB1-35</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the plan related to the release e.g. KUNG-FOO</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The name of the plan related to the release e.g. Kung - Foo</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the plan related to the release (without project part), e.g. MAIN</td>
</tr>
</tbody>
</table>
bamboo.shortPlanName | The plan's name without project part, e.g. Some plan name

Note that several of the variables in the above table are actually those associated with the build plan.

System variables

The usage format for all system variables is:

$\{\text{system.<variable>}\}$

For example, if you have a system variable $\text{MYPATH}=C:\MyPath$; you can use a Bamboo system variable $\text{system.MYPATH}$ which will inherit the same value as the system variable.

In older Bamboo versions using 'PATH' in the Environment Variables field (of a Script task) doesn't set the windows PATH variable, whereas using 'Path' sets Path and PATH in cmd shell.

Using variables in bash

Bamboo variables are exported as bash shell variables. All full stops (periods) are converted to underscores. For example, the variable $\text{bamb oo.my.variable}$ is $\text{bamboo_my_variable}$ in bash. This is related to File Script tasks (not Inline Script tasks).

Jira applications variables

Note that these variables can be accessed from a Bamboo build only when that build was triggered by releasing a version in Jira Software Server.

<table>
<thead>
<tr>
<th>Jira variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>${\text{bamboo.jira.baseUrl}}$</td>
<td>The URL of your Jira application server.</td>
</tr>
<tr>
<td>${\text{bamboo.jira.projectKey}}$</td>
<td>The key of the triggering Jira application project.</td>
</tr>
<tr>
<td>${\text{bamboo.jira.projectName}}$</td>
<td>The name of the triggering Jira application project.</td>
</tr>
<tr>
<td>${\text{bamboo.jira.version}}$</td>
<td>The release version of the triggering Jira application project.</td>
</tr>
<tr>
<td>${\text{bamboo.jira.username}}$</td>
<td>The username of the user who triggered the release build.</td>
</tr>
</tbody>
</table>

Examples

Maven examples

For example, you may want your Maven 2 version to be determined by Bamboo. In Maven 2 `pom.xml` you may have:

```xml
...  
<groupId>com.atlassian.boo</groupId>
<artifactId>boo-test</artifactId>
<packaging>jar</packaging>
.VERSION>1.1.$\{bambooBuildNumber\}-SNAPSHOT</version>
...  
```

You can then specify the following in the Goal field of your build plan:

```
clean package -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Maven build to use. The command will then produce a jar that looks like this: `boo-test-1.1.1102-SNAPSHOT.jar`.

Ant examples

You can then specify the following in the Target field of your build plan:
When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Ant build to use.

**Specifying capabilities as variables**

You can also specify a capability to be used in a similar way to a global variable.

The format of the capability should be as follows:

```text
${bamboo.capability.<capability_key>}
```

For example,

- **Custom**
  ```text
  ${bamboo.capability.<capability_key>}
  ```

- **JDK**
  ```text
  ${bamboo.capability.system.jdk.<jdk_label>}
  ```

- **Builder**
  ```text
  ${bamboo.capability.system.builder.<builder_type>.<builder_label>}
  ```
  e.g. `${bamboo.capability.system.builder.maven.Maven1}`

- **Perforce**
  ```text
  ${bamboo.capability.system.p4Executable}
  ```

If you click on a capability, the specific capability key will be contained in the URL.

Please note, the space characters in the URL will be replaced with `+` characters. We recommend that you do not use capability labels with space characters, if you wish to use them as variables. A possible solution for space characters is to format them with `${}` symbols, however, this does not work in all cases.

**Using capabilities**

Global and Build-Specific Variables can be used in a specific fields of your build plan, as specified above. For capabilities,

- **System Capabilities** are available to all of these fields, (i.e. global and build-specific).
- **Agent Capabilities** (i.e. agent-specific and shared/server capabilities) are available only to the build-specific fields. (i.e. not available to Repository URL, CVS Root or Branch name.)

For example,
If you wanted to specify a system variable, but have it set to different values on each agent, do the following:

- Set the following as a system environment variable field on the **Builder** tab:

  
  ```
  $(bamboo.capability.thatsystemvariable)
  ```

- Specify the system environment variable as a custom capability on each of your agents, and set to the capability to the different values, as desired.

### Deprecated variables

The following variables are deprecated and are subject for removal in future Bamboo releases:

<table>
<thead>
<tr>
<th>Generic repository variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.repository.revision.number</td>
<td>The revision number.</td>
</tr>
<tr>
<td>bamboo.repository.branch.name</td>
<td>The repository branch name (for Bamboo version 4.2 or later).</td>
</tr>
<tr>
<td>bamboo.repository.previous.revision.number</td>
<td>The previous revision number (might not exist, for example for the initial build).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Subversion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.custom.svn.revision.number</td>
<td>The revision number.</td>
</tr>
<tr>
<td>bamboo.custom.svn.lastchange.revision.number</td>
<td>The last changed revision number.</td>
</tr>
<tr>
<td>bamboo.custom.svn.username</td>
<td>User name used for repository authentication.</td>
</tr>
<tr>
<td>bamboo.repository.svn.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.revision.number</td>
<td>The revision number.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.lastchange.revision.number</td>
<td>The last-changed revision number.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CVS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.custom.cvs.last.update.time</td>
<td>The last updated timestamp.</td>
</tr>
</tbody>
</table>
| bamboo.custom.cvs.last.update.time.label                                                     | The last updated timestamp to be used as a label for post build result labeling. The spaces in the CVS version string are replaced with `_`.

<table>
<thead>

<td>The branch.</td>
</tr>
<tr>
<td>bamboo.repository.hg.username</td>
<td>User name, used for repository authentication.</td>
</tr>
</tbody>
</table>

### Bamboo variables v6.3

Variables can be used to make values available when building plans in Bamboo.

- **Build-specific variables** are evaluated by Bamboo dynamically at build time. The source of a build-specific variable can either be a Bamboo property or one of the default plugins (assuming it is enabled).
- **Deployment variables** are available when deploying a project.
- **System variables** also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- **Global variables** are defined across your entire Bamboo instance, and have the same (static) value for every plan that is built by Bamboo. See [Defining global variables](#).
- **Plan variables** are similar to global variables, but are defined for specific plans. Plan variables override global variables with the same name. You can also override a plan variable for a build if you trigger the build manually. See [Defining plan variables](#).

### Using variables

Variables can be used in all fields of a task or deployment, with the exception of password fields. Use the following format when referencing a variable:

```
${bamboo.variableName}
```

You can override a plan variable for a build, if you trigger the build manually. See [Triggering a plan build manually](#).

You can reference a variable from another variables, e.g. consider having the following variables:

- `var1 = Hello`
- `var2 = world`

You can create another variable which references the two other ones

```
greet

${bamboo.var1} ${bamboo.var2}!
```

Bamboo will resolve the variable as *Hello World!*

You can:

- reference a global or context specific variable in a build plan or deployment project
- reference a variable which references another one, deep recursion is allowed

There are couple of limitations:

- referencing a variable which isn’t defined is an error, whole build or deployment will fail if you reference such variable
- cycles are not allowed and are considered as build or deployment project error.

### Defining custom variables

You can define your own custom variables, using a similar format to that above, however you cannot create a variable name that is already in use by Bamboo.

For information on how to define your own variables in Bamboo, see:

- **Defining global variables**
- **Defining plan variables**
- **Defining deployment environment variables**

*Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.*
Build-specific variables

The following build-specific variables are available by default:

- **System variables** apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- In the variable names from the table, `<position>` is an optional parameter that specifies the position of the repository in the plan's repository list. If omitted, the first repository in the list is used.
- Third-party repository plugins can expose their own variables.

<table>
<thead>
<tr>
<th>Build-specific variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildKey</td>
<td>The job key for the current job, in the form PROJECT-PLAN-JOB, e.g. BAM-MAIN-JOBX</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the current plan, in the form PROJECT-PLAN, e.g. BAM-MAIN</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the current plan (without project part), e.g. MAIN</td>
</tr>
<tr>
<td>bamboo.shortJobKey</td>
<td>The short key of the current job (without project and plan parts), e.g. JOBX</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The result key when this job executes, in the form PROJECT-PLAN-JOB-BUILD e.g. BAM-BOO-JOB1-8, where '8' is the build number. For deployment projects this variable will not have the JOB component e.g. PROJ-TP-6.</td>
</tr>
<tr>
<td>bamboo.buildResultsUrl or bamboo.resultsUrl</td>
<td>The URL of the result in Bamboo once the job has finished executing.</td>
</tr>
<tr>
<td>bamboo.buildNumber</td>
<td>The Bamboo build number, e.g. 123</td>
</tr>
<tr>
<td>bamboo.buildPlanName</td>
<td>The Bamboo job name e.g. Some Project name - Some plan name - Some job name</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The current plan's name e.g. Some project name - Some plan name</td>
</tr>
<tr>
<td>bamboo.shortPlanName</td>
<td>The current plan's name without project part, e.g. Some plan name</td>
</tr>
<tr>
<td>bamboo.shortJobName</td>
<td>The current job's name without project and plan parts, e.g. Some job name</td>
</tr>
<tr>
<td>bamboo.buildTimeStamp</td>
<td>The time when build was started in ISO 8601 format e.g. 2010-01-01T00:00:00+01:00</td>
</tr>
<tr>
<td>bamboo.agentId</td>
<td>The ID of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td>bamboo.agentWorkingDirectory</td>
<td>The path to the working directory on the agent, for example &lt;HOME&gt;/xml-data/build-dir.</td>
</tr>
<tr>
<td></td>
<td>The agent working directory is not the same as the build working directory described below.</td>
</tr>
<tr>
<td>bamboo.build.working.directory</td>
<td>The working directory on which the build is being executed, for example &lt;HOME&gt;/xml-data/build-dir/AV-AVT-JOB1.</td>
</tr>
<tr>
<td>bamboo.ManualBuildTriggerReason.userName</td>
<td>The user who triggered the manual build.</td>
</tr>
</tbody>
</table>

Generic repository variables

- bamboo.planRepository.<position>.branchName: The name of the branch in the repository (depends on availability from the VCS used) e.g. default
- bamboo.planRepository.<position>.name: The name of the repository, as shown in the repository for the plan e.g. Mercurial
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.revision</td>
<td>The revision use to build this release. Format depends on the VCS used.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.previousRevision</td>
<td>The previous revision number (this might not exist, for example for the initial build).</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.type</td>
<td>The type of the repository, as defined by a repository plugin e.g. hg, svn, git</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.username</td>
<td>User name, used for repository authentication.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.last.update.time</td>
<td>The last updated timestamp.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.last.update.time.label</td>
<td>The last updated timestamp to be used as a label for post build result labeling. The spaces in the cvs version string are replaced with &quot;.&quot;.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.revision.number</td>
<td>The change set number.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.username</td>
<td>User name, used for repository authentication.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.port</td>
<td>Port used for repository communication.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.client</td>
<td>Client used for repository communication.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.branch</td>
<td>The branch</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.branch</td>
<td>The branch</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.username</td>
<td>User name, used for repository authentication.</td>
</tr>
</tbody>
</table>

- System variables also apply across your entire Bamboo instance and inherit their values from system or environment variables of the same name.
- In the variable names from the table above, <position> is an optional parameter that specifies the position of the repository in the plan's repository list. If omitted, the first repository in the list is used.
- Third-party repository plugins can expose their own variables.

**Build dependency variables**

The following build dependency variables are also available:

<table>
<thead>
<tr>
<th>Build-specific variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.dependency.parent.#</td>
<td>Allows a child build to query the build key of the triggering parent build, where # represents the position in the build tree - 0 at the top, 1 the following, and so on. The $[bamboo.dependency.parent.0] variable can be viewed in the child plan's metadata tab.</td>
</tr>
<tr>
<td>bamboo.dependency.parent.total</td>
<td>The total # of parent builds.</td>
</tr>
</tbody>
</table>

**Deployment variables**

Bamboo manages a number of standard reserved variables that are available when deploying a project.

Variables later in the following list override the previous ones in case of repeating names:

- global variables
- release variables as defined below
- user variables defined at environment level
The autogenerated variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.agentId</td>
<td>The id of the agent that the deployment is executed on.</td>
</tr>
<tr>
<td>bamboo.agentWorkingDirectory</td>
<td>The path to the working directory on the agent. This is not the same as the Bamboo working directory.</td>
</tr>
<tr>
<td>bamboo.build.working.directory</td>
<td>The path to the working directory for Bamboo. This is used by both the build plan and the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.environment</td>
<td>The name of the environment that the release is to be deployed to.</td>
</tr>
<tr>
<td>bamboo.deploy.project</td>
<td>The name of the deployment project.</td>
</tr>
<tr>
<td>bamboo.deploy.rollback</td>
<td>True if the release being deployed is older than the release being replaced.</td>
</tr>
<tr>
<td>bamboo.deploy.release</td>
<td>The name of the release that is being deployed. Either .release or .version can be used - both return the name of the release being deployed.</td>
</tr>
<tr>
<td>bamboo.deploy.version</td>
<td></td>
</tr>
<tr>
<td>bamboo.deploy.release.previous</td>
<td>The name of the release that is being replaced (if available). Either .release or .version can be used - both return the name of the release being replaced.</td>
</tr>
<tr>
<td>bamboo.deploy.version.previous</td>
<td></td>
</tr>
<tr>
<td>bamboo.resultsUrl</td>
<td>The URL to the screen in Bamboo that displays build results.</td>
</tr>
</tbody>
</table>

You can generate variables of your own, using a similar format, however you cannot create a variable that is already in use by Bamboo. See Defining deployment environment variables for more information.

Releases variables

Bamboo makes the following types of variables available for deployment releases:

- Snapshots of values for global variables.
- Snapshots of values for plan variables.
- Snapshots of values of repository variables.
- The autogenerated release variables in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.buildNumber</td>
<td>The build result from which the release is created.</td>
</tr>
<tr>
<td>bamboo.buildResultKey</td>
<td>The key of the build result from which the release is created e.g. KUNG-FOO-JOB1-35</td>
</tr>
<tr>
<td>bamboo.planKey</td>
<td>The key of the plan related to the release e.g. KUNG-FOO</td>
</tr>
<tr>
<td>bamboo.planName</td>
<td>The name of the plan related to the release e.g. Kung - Foo</td>
</tr>
<tr>
<td>bamboo.shortPlanKey</td>
<td>The short key of the plan related to the release (without project part), e.g. MAIN</td>
</tr>
<tr>
<td>bamboo.shortPlanName</td>
<td>The plan's name without project part, e.g. Some plan name</td>
</tr>
</tbody>
</table>

Note that several of the variables in the above table are actually those associated with the build plan.

System variables

The usage format for all system variables is:

```
${system.<variable>}
```

For example, if you have a system variable MYPATH=C:\MyPath; you can use a Bamboo system variable system.MYPATH which will inherit the same value as the system variable.

In older Bamboo versions using 'PATH' in the Environment Variables field (of a Script task) doesn't set the windows PATH variable, whereas using 'Path' sets Path and PATH in cmd shell.

Using variables in bash

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Bamboo variables are exported as bash shell variables. All full stops (periods) are converted to underscores. For example, the variable `bamb oo.my.variable` is `${bamboo_my_variable}` in bash. This is related to File Script tasks (not Inline Script tasks).

### Jira applications variables

Note that these variables can be accessed from a Bamboo build only when that build was triggered by releasing a version in Jira Software Server.

<table>
<thead>
<tr>
<th>Jira variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>${bamboo.jira.baseUrl}</code></td>
<td>The URL of your Jira application server.</td>
</tr>
<tr>
<td><code>${bamboo.jira.projectKey}</code></td>
<td>The key of the triggering Jira application project.</td>
</tr>
<tr>
<td><code>${bamboo.jira.projectName}</code></td>
<td>The name of the triggering Jira application project.</td>
</tr>
<tr>
<td><code>${bamboo.jira.version}</code></td>
<td>The release version of the triggering Jira application project.</td>
</tr>
<tr>
<td><code>${bamboo.jira.username}</code></td>
<td>The username of the user who triggered the release build.</td>
</tr>
</tbody>
</table>

### Examples

#### Maven examples

For example, you may want your Maven 2 version to be determined by Bamboo. In Maven 2 `pom.xml` you may have:

```xml
...  
<groupId>com.atlassian.boo</groupId>  
<artifactId>boo-test</artifactId>  
<packaging>jar</packaging>  
<version>1.1.${bambooBuildNumber}-SNAPSHOT</version>  
...  
```

You can then specify the following in the **Goal** field of your build plan:

```
clean package -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Maven build to use. The command will then produce a jar that looks like this: `boo-test-1.1.1102-SNAPSHOT.jar`.

#### Ant examples

You can then specify the following in the **Target** field of your build plan:

```
-f build.xml -DbambooBuildNumber=${bamboo.buildNumber}
```

When the command runs, Bamboo will replace the `buildNumber` with the actual number (e.g. 1102), which will be passed to the underlying Ant build to use.

### Specifying capabilities as variables

You can also specify a capability to be used in a similar way to a global variable.

The format of the capability should be as follows:

```
${bamboo.capability.<capability_key>}
```

For example,
Custom

\texttt{$\{\text{bamboo.capability.<capability_key>}\}$}

JDK

\texttt{$\{\text{bamboo.capability.system.jdk.<jdk_label>}\}$}

Builder

\texttt{$\{\text{bamboo.capability.system.builder.<builder_type>.<builder_label>}\}$}

\texttt{\textit{e.g.} $\{\text{bamboo.capability.system.builder.maven.Maven1}\}$}

Perforce

\texttt{$\{\text{bamboo.capability.system.p4Executable}\}$}

If you click on a capability, the specific capability key will be contained in the URL.

Please note, the space characters in the URL will be replaced with `＋` characters. We recommend that you do not use capability labels with space characters, if you wish to use them as variables. A possible solution for space characters is to format them with `\{\}` symbols, however, this does not work in all cases.

Using capabilities

Global and Build-Specific Variables can be used in a specific fields of your build plan, as specified above. For capabilities,

- **System Capabilities** are available to all of these fields, (i.e. global and build-specific).
- **Agent Capabilities** (i.e. agent-specific and shared/server capabilities) are available only to the build-specific fields. (i.e. not available to Repository URL, CVS Root or Branch name.)

For example,

If you wanted to specify a system variable, but have it set to different values on each agent, do the following:

- Set the following as a system environment variable field on the **Builder** tab:

  \texttt{$\{\text{bamboo.capability.thatsystemvariable}\}$}

- Specify the system environment variable as a custom capability on each of your agents, and set to the capability to the different values, as desired.

Deprecated variables

The following variables are deprecated and are subject for removal in future Bamboo releases:

<table>
<thead>
<tr>
<th>Generic repository variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{bamboo.repository.revision.number}</td>
<td>The revision number.</td>
</tr>
<tr>
<td>\texttt{bamboo.repository.branch.name}</td>
<td>The repository branch name (for Bamboo version 4.2 or later).</td>
</tr>
<tr>
<td>\texttt{bamboo.repository.previous.revision.number}</td>
<td>The previous revision number (might not exist, for example for the initial build).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Subversion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{bamboo.custom.svn.revision.number}</td>
<td>The revision number.</td>
</tr>
<tr>
<td>\texttt{bamboo.custom.svn.lastchange.revision.number}</td>
<td>The last changed revision number.</td>
</tr>
<tr>
<td>Variable Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>bamboo.custom.svn.username</td>
<td>User name used for repository authentication.</td>
</tr>
<tr>
<td>bamboo.repository.svn.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.revision.number</td>
<td>The revision number.</td>
</tr>
<tr>
<td>bamboo.planRepository.&lt;position&gt;.lastchange.revision.number</td>
<td>The last-changed revision number.</td>
</tr>
</tbody>
</table>

**CVS**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.custom.cvs.last.update.time</td>
<td>The last updated timestamp.</td>
</tr>
<tr>
<td>bamboo.custom.cvs.last.update.time.label</td>
<td>The last updated timestamp to be used as a label for post build result labeling. The spaces in the CVS version string are replaced with '_'.</td>
</tr>
</tbody>
</table>

**Perforce**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.custom.p4.revision.number</td>
<td>The change set number.</td>
</tr>
<tr>
<td>bamboo.custom.p4.username</td>
<td>User name used for repository authentication.</td>
</tr>
<tr>
<td>bamboo.custom.p4.port</td>
<td>Port used for repository communication.</td>
</tr>
<tr>
<td>bamboo.custom.p4.client</td>
<td>Client used for repository communication.</td>
</tr>
</tbody>
</table>

**Git**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.repository.git.branch</td>
<td>The branch.</td>
</tr>
<tr>
<td>bamboo.repository.git.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
</tbody>
</table>

**Mercurial**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.repository.hg.repositoryUrl</td>
<td>The repository URL.</td>
</tr>
<tr>
<td>bamboo.repository.hg.branch</td>
<td>The branch.</td>
</tr>
<tr>
<td>bamboo.repository.hg.username</td>
<td>User name, used for repository authentication.</td>
</tr>
</tbody>
</table>

### Bamboo permissions

Bamboo provides the following types of permissions to allow fully customizable control of access to the continuous delivery workflow:

- Global permissions
- Build plan permissions
- Project permissions
- Deployment permissions
  - Deployment project permissions
  - Deployment environment permissions

**Permissions key:**

- 🟢 - Permission is set by default
- 🌟 - Permission is available as an option
- 🚫 - Permission not available, even as an option

**On this page:**

- Global permissions
- Build plan permissions
- Project permissions
- Deployment permissions
  - Deployment projects
  - Deployment environments
- Permission dependencies

Starting from Bamboo version 6.2, permissions become additive. Once you’re assigned permissions on any level, you’ll automatically have permissions on lower levels. You can’t override or remove permissions on lower levels. For example, if you have **Create** permission of a global level, you can create plans on all levels. Another example, if you have **Build** permission assigned to you on a project level and none assigned on the plan level explicitly, you will still have build permissions for that plan anyhow.

### Global permissions
Global permissions level control the ability to view the system, create a new build plan and use administration tools. Global application permissions are accessed from the Global permissions page within the Bamboo administration pages.

<table>
<thead>
<tr>
<th>User type</th>
<th>Access</th>
<th>Create</th>
<th>Create repository</th>
<th>Restricted admin</th>
<th>Admin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✓</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✓</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Administrator</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

Key:
- **Access** - log in to Bamboo; this permissions does not give you any additional permission.
- **Create** - create new plans, projects and deployment projects in Bamboo.
- **Create repository** - create and manage linked repositories.
- **Restricted admin** - perform some administration operations and view all plans in Bamboo; this role excludes permissions that directly influence the host on which the Bamboo Server is located, however, all plan administration and agent administration is available to restricted admins.
- **Admin** - perform all operations and view all plans in Bamboo.

Build plan permissions

Build plan permissions allow a user to control access to the functions of the build plan. These include viewing, editing, building, cloning and administering a build plan. Build plan level permissions are accessed from the build plan configuration page.

<table>
<thead>
<tr>
<th>User</th>
<th>View</th>
<th>Edit</th>
<th>Build</th>
<th>Clone</th>
<th>Admin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✷</td>
<td>✴</td>
<td>✷</td>
<td>✷</td>
<td>✷</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✷</td>
<td>✴</td>
<td>✷</td>
<td>✷</td>
<td>✷</td>
</tr>
<tr>
<td>Administrator</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

Key:
- **View** - view the plan and its builds; when creating a new plan, check the **Allow all users to view this plan** to allow anonymous and logged-in users view your plan.
- **Edit** - view and edit the configuration of the plan and its jobs, not including permissions or stages.
- **Build** - trigger a manual build, or suspend and resume the plan.
- **Clone** - clone the plan.
- **Admin** - edit all aspects of the plan including permissions and stages.

Project permissions

Project permissions allow you to control access to project permissions and settings. See Configuring project permissions.

<table>
<thead>
<tr>
<th>User</th>
<th>Create plan</th>
<th>Admin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✷</td>
<td>✷</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✷</td>
<td>✷</td>
</tr>
<tr>
<td>Administrator</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

Key:
- **Create plan** - create plans for the project
- **Admin** -
  - manage permissions for the project
  - manage permissions for all plans in a project
  - change project settings

Deployment permissions

Bamboo's deployments features allow you to control permissions for both deployment projects and deployment environments.
Deployment projects

<table>
<thead>
<tr>
<th>User</th>
<th>View</th>
<th>Edit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✔</td>
<td>✗</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✔</td>
<td>✘</td>
</tr>
<tr>
<td>Administrator</td>
<td>✔</td>
<td>✔</td>
</tr>
</tbody>
</table>

Key:
- **View** - view the project and its associated environments.
- **Edit** - edit the project, its related plan and environment configuration, and create releases.

Deployment environments

<table>
<thead>
<tr>
<th>User</th>
<th>View</th>
<th>Edit</th>
<th>Deploy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✔</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✔</td>
<td>✘</td>
<td>✘</td>
</tr>
<tr>
<td>Administrator</td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
</tbody>
</table>

Key:
- **View** - view the project and its associated environments. You must also have view permission on the deployment project.
- **Edit** - edit the environment.
- **Deploy** - deploy releases to this environment and create releases for this project.

Permission dependencies

To ensure the consistency of Bamboo permissions, starting with Bamboo 6.3, we provide an update mechanism which will fix all inconsistencies for all permissions in your Bamboo environment. We have also modified all the pages where you can edit permissions in a way which won’t allow granting inconsistent or clashing permissions in the future.

If you want to revoke a lower-level permission for a user, you must revoke the higher-level permissions first. Also, when granting a higher-level permission to a user, all relevant lower-level permissions will be granted automatically to that user.

Permission consistency might still be broken when using third-party plugins.

Bamboo permissions v5.14

Bamboo provides the following types of permissions to allow fully customizable control of access to the continuous delivery workflow:

- Global permissions
- Build plan permissions
- Deployment permissions
  - Deployment project permissions
  - Deployment environment permissions

Permissions key:
- ✔ - Permission is set by default
- ✭ - Permission is available as an option
- ✗ - Permission not available, even as an option

On this page:
- Global permissions
- Build plan permissions
- Deployment permissions
  - Deployment projects
  - Deployment environments
Global permissions

Global permissions level control the ability to view the system, create a new build plan and use administration tools. Global application permissions are accessed from the Global permissions page within the Bamboo administration pages.

<table>
<thead>

*Only enabled on the evaluation license

Key:

- **Access** - access Bamboo.
- **Create plan** - create a new plan in Bamboo.
- **Create repository** - create and manage linked repositories.
- **Restricted admin** - perform some administration operations and view all plans in Bamboo; this role excludes permissions that directly influence the host on which the Bamboo Server is located, however, all plan administration and agent administration is available to restricted admins.
- **Admin** - perform all operations and view all plans in Bamboo.

Build plan permissions

Build plan permissions allow a user to control access to the functions of the build plan. These include viewing, editing, building, cloning and administering a build plan. Build plan level permissions are accessed from the build plan configuration page.

<table>
<thead>
<tr>
<th>User</th>
<th>View</th>
<th>Edit</th>
<th>Build</th>
<th>Clone</th>
<th>Admin</th>

Bamboo provides the following types of permissions to allow fully customizable control of access to the continuous delivery workflow:

- Global permissions
- Build plan permissions
- Deployment permissions
  - Deployment project permissions
  - Deployment environment permissions

Permissions key:
- ✔️ - Permission is set by default
- 🌟 - Permission is available as an option
- ❌ - Permission not available, even as an option

On this page:
- Global permissions
- Build plan permissions
- Deployment permissions
  - Deployment projects
  - Deployment environments

Starting from Bamboo version 6.2, permissions become additive. Once you’re assigned permissions on any level, you’ll automatically have permissions on lower levels. You can’t override or remove permissions on lower levels. For example, if you have Create permission of a global level, you can create plans on all levels. Another example, if you have Build permission assigned to you on a project level and none assigned on the plan level explicitly, you will still have build permissions for that plan anyhow.

Global permissions

Global permissions level control the ability to view the system, create a new build plan and use administration tools. Global application permissions are accessed from the Global permissions page within the Bamboo administration pages.

<table>
<thead>
<tr>
<th>User type</th>
<th>Access</th>
<th>Create</th>
<th>Create repository</th>
<th>Restricted admin</th>
<th>Admin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✔️</td>
<td>❌</td>
<td>❌</td>
<td>❌</td>
<td>❌</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✔️</td>
<td>❌</td>
<td>🌟</td>
<td>✔️</td>
<td>✔️</td>
</tr>
<tr>
<td>Administrator</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
</tr>
<tr>
<td>Project administrator</td>
<td>✔️</td>
<td>❌</td>
<td>❌</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Bamboo evaluator*</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
<td>✗</td>
<td>✔️</td>
</tr>
<tr>
<td>Bamboo-admin group</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
</tr>
</tbody>
</table>

*Only enabled on the evaluation license

Key:
- **Access** - access Bamboo.
- **Create plan** - create a new plan in Bamboo; from Bamboo version 6.2 this permission also allows you to create empty projects.
- **Create repository** - create and manage linked repositories.
- **Restricted admin** - perform some administration operations and view all plans in Bamboo; this role excludes permissions that directly influence the host on which the Bamboo Server is located, however, all plan administration and agent administration is available to restricted admins.
- **Admin** - perform all operations and view all plans in Bamboo.

Build plan permissions

Build plan permissions allow a user to control access to the functions of the build plan. These include viewing, editing, building, cloning and administering a build plan. Build plan level permissions are accessed from the build plan configuration page.
Deployment permissions

Bamboo’s deployments features allow you to control permissions for both deployment projects and deployment environments.

</tr>
<tr>
<td>Logged-in</td>
<td>✓</td>
<td>✩</td>
<td></td>
</tr>
<tr>
<td>Administrator</td>
<td>✓</td>
<td>✓</td>
<td></td>
</tr>
</tbody>
</table>

Key:
- **View** - view the project and its associated environments. You must also have view permission on the deployment project.
- **Edit** - edit the environment.
- **Deploy** - deploy releases to this environment and create releases for this project.

Bamboo permissions v6.2

Bamboo provides the following types of permissions to allow fully customizable control of access to the continuous delivery workflow:

- Global permissions
- Build plan permissions
- Project permissions
- Deployment permissions
  - Deployment project permissions
  - Deployment environment permissions

Permissions key:
- ✓ - Permission is set by default
- ✩ - Permission is available as an option
- ✗ - Permission not available, even as an option
Global permissions

Global permissions level control the ability to view the system, create a new build plan and use administration tools. Global application permissions are accessed from the Global permissions page within the Bamboo administration pages.

<table>
<thead>
<tr>
<th>User type</th>
<th>Access</th>
<th>Create</th>
<th>Create repository</th>
<th>Restricted admin</th>
<th>Admin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✓</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Logged-in</td>

<td>✗</td>
<td>✗</td>
<td>✗</td>
<td>✓</td>
</tr>
<tr>
<td>Administrator</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✗</td>
<td>✓</td>
</tr>
</tbody>
</table>

Key:
- **Access** - log in to Bamboo; this permissions does not give you any additional permission.
- **Create** - create new plans, projects and deployment projects in Bamboo.
- **Create repository** - create and manage linked repositories.
- **Restricted admin** - perform some administration operations and view all plans in Bamboo; this role excludes permissions that directly influence the host on which the Bamboo Server is located, however, all plan administration and agent administration is available to restricted admins.
- **Admin** - perform all operations and view all plans in Bamboo.

Build plan permissions

Build plan permissions allow a user to control access to the functions of the build plan. These include viewing, editing, building, cloning and administering a build plan. Build plan level permissions are accessed from the build plan configuration page.

<table>
<thead>
<tr>
<th>User</th>
<th>View</th>
<th>Edit</th>
<th>Build</th>
<th>Clone</th>
<th>Admin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✷</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>

</tr>
<tr>
<td>Logged-in</td>
<td>✷</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Administrator</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

Key:
- **View** - view the plan and its builds; when creating a new plan, check the Allow all users to view this plan to allow anonymous and logged-in users view your plan.
- **Edit** - view and edit the configuration of the plan and its jobs, not including permissions or stages.
- **Build** - trigger a manual build, or suspend and resume the plan.
- **Clone** - clone the plan.
- **Admin** - edit all aspects of the plan including permissions and stages.

Project permissions

Project permissions allow you to control access to project permissions and settings. See Configuring project permissions.
### Deployment permissions

Bamboo's deployments features allow you to control permissions for both deployment projects and deployment environments.

#### Deployment projects

<table>
<thead>
<tr>
<th>User</th>
<th>View</th>
<th>Edit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✔</td>
<td>✗</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✔</td>
<td>✗</td>
</tr>
<tr>
<td>Administrator</td>
<td>✔</td>
<td>✔</td>
</tr>
</tbody>
</table>

**Key:**
- **View** - view the project and its associated environments.
- **Edit** - edit the project, its related plan and environment configuration, and create releases.

#### Deployment environments

<table>
<thead>
<tr>
<th>User</th>
<th>View</th>
<th>Edit</th>
<th>Deploy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✔</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✔</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Administrator</td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
</tbody>
</table>

**Key:**
- **View** - view the project and its associated environments. You must also have view permission on the deployment project.
- **Edit** - edit the environment.
- **Deploy** - deploy releases to this environment and create releases for this project.

### Bamboo permissions v6.3

Bamboo provides the following types of permissions to allow fully customizable control of access to the continuous delivery workflow:

- **Global permissions**
- **Build plan permissions**
- **Project permissions**
- **Deployment permissions**
  - Deployment project permissions
  - Deployment environment permissions

**Permissions key:**
- **✔** - Permission is set by default
- **★** - Permission is available as an option
- **✗** - Permission not available, even as an option
Global permissions

Global permissions level control the ability to view the system, create a new build plan and use administration tools. Global application permissions are accessed from the Global permissions page within the Bamboo administration pages.

<table>
<thead>
<tr>
<th>User type</th>
<th>Access</th>
<th>Create</th>
<th>Create repository</th>
<th>Restricted admin</th>
<th>Admin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✔️</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✔️</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Administrator</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
</tr>
</tbody>
</table>

Key:
- **Access** - log in to Bamboo; this permissions does not give you any additional permission.
- **Create** - create new plans, projects and deployment projects in Bamboo.
- **Create repository** - create and manage linked repositories.
- **Restricted admin** - perform some administration operations and view all plans in Bamboo; this role excludes permissions that directly influence the host on which the Bamboo Server is located, however, all plan administration and agent administration is available to restricted admins.
- **Admin** - perform all operations and view all plans in Bamboo.

Build plan permissions

Build plan permissions allow a user to control access to the functions of the build plan. These include viewing, editing, building, cloning and administering a build plan. Build plan level permissions are accessed from the build plan configuration page.

<table>
<thead>
<tr>
<th>User</th>
<th>View</th>
<th>Edit</th>
<th>Build</th>
<th>Clone</th>
<th>Admin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>★</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Logged-in</td>
<td>★</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Administrator</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
</tr>
</tbody>
</table>

Key:
- **View** - view the plan and its builds; when creating a new plan, check the **Allow all users to view this plan** to allow anonymous and logged-in users view your plan.
- **Edit** - view and edit the configuration of the plan and its jobs, not including permissions or stages.
- **Build** - trigger a manual build, or suspend and resume the plan.
- **Clone** - clone the plan.
- **Admin** - edit all aspects of the plan including permissions and stages.

Project permissions

Project permissions allow you to control access to project permissions and settings. See Configuring project permissions.
Anonymous
Logged-in
Administrator

Key:

- **Create plan** - create plans for the project
- **Admin** -
  - manage permissions for the project
  - manage permissions for all plans in a project
  - change project settings

Deployment permissions

Bamboo's deployments features allow you to control permissions for both deployment projects and deployment environments.

**Deployment projects**

<table>
<thead>
<tr>
<th>User</th>
<th>View</th>
<th>Edit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✅</td>
<td>✗</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✅</td>
<td>✗</td>
</tr>
<tr>
<td>Administrator</td>
<td>✅</td>
<td>✅</td>
</tr>
</tbody>
</table>

Key:

- **View** - view the project and its associated environments.
- **Edit** - edit the project, its related plan and environment configuration, and create releases.

**Deployment environments**

<table>
<thead>
<tr>
<th>User</th>
<th>View</th>
<th>Edit</th>
<th>Deploy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anonymous</td>
<td>✅</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Logged-in</td>
<td>✅</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>Administrator</td>
<td>✅</td>
<td>✅</td>
<td>✅</td>
</tr>
</tbody>
</table>

Key:

- **View** - view the project and its associated environments. You must also have view permission on the deployment project.
- **Edit** - edit the environment.
- **Deploy** - deploy releases to this environment and create releases for this project.

Permission dependencies

To ensure the consistency of Bamboo permissions, starting with Bamboo 6.3, we provide an update mechanism which will fix all inconsistencies for all permissions in your Bamboo environment. We have also modified all the pages where you can edit permissions in a way which won’t allow granting inconsistent or clashing permissions in the future.

If you want to revoke a lower-level permission for a user, you must revoke the higher-level permissions first. Also, when granting a higher-level permission to a user, all relevant lower-level permissions will be granted automatically to that user.

Permission consistency might still be broken when using third-party plugins.

Quick filters for Bamboo

Use quick filters for handy search shortcuts in your Bamboo build dashboard. Create filters based on configurable rules and never miss a build plan again.

Quick filters work only with plans displayed in Bamboo dashboard, which means that they don't include plan branches.
Configuration

Administrators can add, edit, and delete quick filters in Administration

> Plans > Quick filters.

If you already have at least one filter, you can also click the cog icon in the quick filters menu:

Quick filters are available in the build dashboard for all users of a Bamboo instance.

Types of rules

Click a filter name in the build dashboard to display plans that match the rules assigned to the filter.

A plan is displayed only if it matches all the rules specified for a filter.

You can create filters with combinations of the following rules:

**By completion date**
Displays plans that completed within a specific time frame. For example, you can display plans that completed in the last three days.

**By label**
Displays plans with a specific label. You can define multiple labels. The plan is display when it has at least one label specified in the rule.

To assign a label to a plan, click the name of a plan to display the plan summary and go to Actions > Modify plan label.

**By name**
Displays plans with a specific name or plans that match a regular expression.

**By project**
Displays plans that are assigned to a specific project. You can select one or more projects.

**By result status**
Displays plans that have completed with a specific result. You can select from:

- Successful
- Failed

**By status**
Displays plans based with a specific status. You can select from:

- Enabled
- Disabled

Quick filters for Bamboo v5.14

Use quick filters for handy search shortcuts in your Bamboo build dashboard. Create filters based on configurable rules and never miss a build plan again.

Quick filters work only with plans displayed in Bamboo dashboard, which means that they don't include plan branches.
Quick filters are available in the build dashboard for all users of a Bamboo instance.

Types of rules

Click a filter name in the build dashboard to display plans that match the rules assigned to the filter.

A plan is displayed only if it matches all the rules specified for a filter.

You can create filters with combinations of the following rules:

<table>
<thead>
<tr>
<th>Rule type name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>By completion date</td>
<td>Displays plans that completed within a specific time frame. For example, you can display plans that completed in the last three days.</td>
</tr>
<tr>
<td>By label</td>
<td>Displays plans with a specific label. You can define multiple labels. The plan is displayed when it has at least one label specified in the rule. To assign a label to a plan, click the name of a plan to display the plan summary and go to Actions &gt; Modify plan label.</td>
</tr>
<tr>
<td>By name</td>
<td>Displays plans with a specific name or plans that match a regular expression.</td>
</tr>
<tr>
<td>By project</td>
<td>Displays plans that are assigned to a specific project. You can select one or more projects.</td>
</tr>
<tr>
<td>By result status</td>
<td>Displays plans that have completed with a specific result. You can select from:</td>
</tr>
<tr>
<td></td>
<td>• Successful</td>
</tr>
<tr>
<td></td>
<td>• Failed</td>
</tr>
<tr>
<td>By status</td>
<td>Displays plans based with a specific status. You can select from:</td>
</tr>
<tr>
<td></td>
<td>• Enabled</td>
</tr>
<tr>
<td></td>
<td>• Disabled</td>
</tr>
</tbody>
</table>

Quick filters for Bamboo v6.1

Use quick filters for handy search shortcuts in your Bamboo build dashboard. Create filters based on configurable rules and never miss a build plan again.

Quick filters work only with plans displayed in Bamboo dashboard, which means that they don't include plan branches.

Configuration

Administrators can add, edit, and delete quick filters in Administration > Plans > Quick filters.

If you already have at least one filter, you can also click the cog icon in the quick filters menu:

Quick filters are available in the build dashboard for all users of a Bamboo instance.
Types of rules

Click a filter name in the build dashboard to display plans that match the rules assigned to the filter.

A plan is displayed only if it matches all the rules specified for a filter.

You can create filters with combinations of the following rules:

- **By completion date**
  Displays plans that completed within a specific time frame. For example, you can display plans that completed in the last three days.

- **By label**
  Displays plans with a specific label. You can define multiple labels. The plan is display when it has at least one label specified in the rule.

  To assign a label to a plan, click the name of a plan to display the plan summary and go to Actions > Modify plan label.

- **By name**
  Displays plans with a specific name or plans that match a regular expression.

- **By project**
  Displays plans that are assigned to a specific project. You can select one or more projects.

- **By result status**
  Displays plans that have completed with a specific result. You can select from:
    - Successful
    - Failed

- **By status**
  Displays plans based with a specific status. You can select from:
    - Enabled
    - Disabled

Unpacking large .ZIP archives

We noticed that the TrueZIP archiver used by Bamboo might be incompatible with some binaries for archives exceeding 4 GB. In order to extract files from a large archive, use the following script:

```bash
A plan is displayed only if it matches all the rules specified for a filter.

By completion date
Displays plans that completed within a specific time frame. For example, you can display plans that completed in the last three days.

By label
Displays plans with a specific label. You can define multiple labels. The plan is display when it has at least one label specified in the rule.

To assign a label to a plan, click the name of a plan to display the plan summary and go to Actions > Modify plan label.

By name
Displays plans with a specific name or plans that match a regular expression.

By project
Displays plans that are assigned to a specific project. You can select one or more projects.

By result status
Displays plans that have completed with a specific result. You can select from:
  - Successful
  - Failed

By status
Displays plans based with a specific status. You can select from:
  - Enabled
  - Disabled

Unpacking large .ZIP archives

We noticed that the TrueZIP archiver used by Bamboo might be incompatible with some binaries for archives exceeding 4 GB. In order to extract files from a large archive, use the following script:

```bash
```
Using Bamboo v6.0

Atlassian Bamboo is a continuous integration (CI) and continuous delivery (CD) server. Bamboo assists software development teams by providing:

- automated building and testing of software source-code status.
- updates on successful/failed builds.
- reporting tools for statistical analysis.
- visibility into, and control over, release artifacts and environments.

This section has information about using Bamboo. Please see Administering Bamboo for information about managing the Bamboo server.

Bamboo Best Practice

Bamboo is a fantastic tool for continuous integration and deployment. It offers a powerful tool for automating software development, however knowledge of some of the tips and tricks that our Bamboo masters use can help reduce friction within your own development cycles.

This user guide has information about how to get the best out of Bamboo, and includes a number of scenarios and best practice approaches. Please see Using Bamboo for more information on specific Bamboo installation, configuration and usage.

Bamboo Best Practice - System Requirements

The recommendations in this guide may not fit all situations and your mileage may vary.

System requirements & considerations

Note that Atlassian currently only supports Bamboo on x86 and 64 bit x86 derived hardware platforms.

Hardware considerations

CPU and memory

For Bamboo, the minimum CPU and memory requirements depend on the size and complexity of your plans. You need to consider:

- Will your builds have functional tests as part of the plans?
- Are your plans executed simultaneously? If so, how many plans will be running at any given time?
- What are the requirements for your running builds, for example do they need large amounts of memory/disk/swap space?
How many users will be using Bamboo at any given time? Like any web application, the system resource needed is proportional to the load experienced by the server.

How many local agents do you plan on running?

- System requirements & considerations

Storage

The Bamboo installation size is approximately 140MB, however, Bamboo's storage requirements depend upon its usage pattern during use. The usage pattern depends on factors such as:

- How many plans you will run
- How many tests each plan will execute
- How many artifacts you are going to have and their size

Atlassian recommends that you allocate about 20GB on top of the Bamboo installation size, and evaluate your usage patterns. Where usage is likely to grow, consider adding additional storage.

Software requirements

Bamboo is a pure Java application and should run on any platform, provided all the JDK requirements are satisfied.

The Supported Platforms page lists the server and client software, and their versions, supported by Bamboo 6.6.

Browser

Disabling JavaScript in your browser, or using a script blocking tool like NoScript, will limit access to Bamboo's full functionality. JavaScript should be enabled.

Java

Bamboo requires the full Java Developers Kit (JDK) platform to be installed on your server's operating system.
Application server

Bamboo is a web application that requires an application server. Currently Apache Tomcat is supported. Tomcat is a stable, lightweight and fast performing application server, however, please note the following:

1. Deploying multiple Atlassian applications in a single Tomcat container is **not supported**. We do not test this configuration and upgrading any of the applications (even for point releases) is likely to break it. There are also a number of known issues with this configuration (see this FAQ for more information).
2. We also do not support deploying multiple Atlassian applications to a single Tomcat container for a number of practical reasons. Firstly, you must shut down Tomcat to upgrade any application and secondly, if one application crashes, the other applications running in that Tomcat container will be inaccessible.
3. Finally, we recommend not deploying any other applications to the same Tomcat container that runs Bamboo, especially if these other applications have large memory requirements or require additional libraries in Tomcat’s `lib` subdirectory.

Database

Bamboo requires a relational database to store its data. Bamboo supports most popular relational database servers, so we suggest using the one that you are most comfortable with administering. Bamboo ships pre-configured with an integrated HSQL database for evaluation purposes only. Since HSQLDB is prone to database corruption, we recommend configuring an external database for production environments.

Hence, if you intend to use Bamboo in a production environment, we **strongly recommend** that you connect Bamboo to a supported enterprise database system.

Other considerations

Bamboo also requires a number of services for efficient operation. You need to consider:

- The database connection pool size.
- The number of local agents.
- The number of remote or elastic agents.

Database connection pool size

The number of database connections available to Bamboo is the lower of two values: your DBMS connection limit and the configured Bamboo connection pool size. From Bamboo 4.2 and later, the Bamboo connection pool size has a default value of 100.

For a small to medium instances (~5 concurrent users, ~5 busy/building local agents, 20 remote agents, 50 plans), the default values are sufficient.

You should increase the connection limit if you notice UI freezes or general sluggish UI performance. Do not decrease the number of available connections below 25.

Note: having too many connections available to Bamboo carries no performance penalty as long as your DBMS can handle the load.

---

**Example: How to estimate the number of db connections**

The following formula gives a rough estimate of the number of database connections that will be required:

\[
\text{(Concurrent users)/5} + \frac{\text{(Busy remote agents)}}{5} + (\text{Local agents})*1.1 + \text{(Amount of concurrent change detections)}
\]

For example, an instance with:

- 5 concurrent users
- 30 busy remote (or elastic) agents
- 30 busy local agents
- 60 plans with repository polling set to 60 second intervals (assume 3 seconds per change detection)

would require \(1 + 6 + 33 + 3 = 43\) connections.

Bamboo ships with a pre-configured connection limit, however this can be modified by editing the following value in your `bamboo.cfg.xml` file:

\[
<\text{property name="hibernate.c3p0.max_size">100</property>\
\]
Local agents considerations

If you run more than 5 concurrently building local agents, you'll probably need to adapt the connection limit because each busy local agent requires a live database connection. Also, note that large amounts of busy (building) local agents can negatively influence the performance of a Bamboo server (and other services running on that host).

Remote and elastic agent considerations

Remote and elastic agents do not require special database connection settings.

Bamboo Best Practice - Using stages

Overview

The basic process for continuous delivery is Build > Test > Publish, which can be repeated multiple times before a release candidate is identified and shipped.

This page describes two approaches to using stages in Atlassian Bamboo. Many people will find that the first approach, 'Continuous integration', will meet their requirements, and we recommend that as a starting point. When you have that operating, you can build on it using more advanced methodologies.

On this page:
- Overview
- Fail fast – detect failures as early as possible
- Artifact promotion – ship the tested binary

See also:
- Bamboo Best Practice - Sharing artifacts
- Bamboo Best Practice - Branching & DVCS

Fail fast – detect failures as early as possible

'Fail fast' is used here in the context of 'continuous integration'. It's a development paradigm that emphasizes the early detection, notification and correction of build failures. Early detection allows early correction, so reducing impact on the project. Furthermore, if we detect problems early, we won't need to execute the rest of the build process, so saving time and resources.

Example Scenario

Let's consider the following simple scenario that uses a series of tasks within a single job. We only need a single stage for this. Typically, unit tests exist in close association with the source files, and are run at, or soon after, compile time.

Task 1 – Check out: We need to check out the relevant code from the repository. Best practice with Bamboo is to set up a linked repository that can be referenced by several plans and that can be updated in just one place. See Checking out code.

Task 2 – Compile: We can configure a 'builder' task to compile the code. If syntax errors are detected, there is no point in performing the unit tests. See Configuring a builder task.

Task 3 – Run unit tests: Unit tests rapidly identify problems with how code runs. This quickly identifies semantic errors. See Configuring a test task.

Task 4 – Create artifact: Often, you will want Bamboo to keep build artifacts, such as reports and binaries, that can be used later. See Sharing artifacts.
Artifact promotion – ship the tested binary

The promotion of build artifacts, especially binaries for use in later phases of the pipeline, is a key concept in continuous integration. Not only can this save time and resources, but crucially, it ensures that a release candidate that could potentially ship to customers contains exactly the code that was tested throughout the pipeline.

In Bamboo, artifact sharing between stages is the mechanism used to promote artifacts.

**Example scenario**

Let's consider the following scenario that adds further stages compared with the Fail Fast scenario above. These extra stages are used to add functional and integration testing, and to provide a manual stage to provide control over when publishing happens.

**Stage 1 – Fail fast:** This is just the continuous integration stage described in the earlier scenario. The generated artifacts are marked for sharing in later stages. See Sharing artifacts.

**Stage 2 – Run functional and integration tests:** We can split these tasks into multiple jobs so they will run in parallel, so reducing the time taken. Each job uses the same artifacts generated in Stage 1. If any job fails, then later stages will not be run.

**Stage 3 – Publish:** We introduce a manual stage here for this example, but this could an automated stage. A manual stage gives us a control point that pauses the pipeline, to allow us, for example, to make a business decision about whether the release candidate should be published, and when. We only run this stage when it has been approved.
Bamboo Best Practice - Branching and DVCS

General overview

No matter how scary it may seem, branching your code is unavoidable - and also a very powerful way to let developers work in isolation on different aspects of your project.

The simplest branching model is that of a master branch and a development branch. The master (or mainline) branch contains the production versions for release. Parallel to master runs the development branch, where developers work on features that will be merged back into master. When sufficient new features have been developed, they will be merged back into master and form the next production release.

The simple model can be extended with other branches to make development work more flexible. These include:

- Feature branches
- Release branches
- Hotfix branches

But because a developer isn't constantly merging changes from master into their development branch, there may be uncertainty about whether the code will work when it is eventually merged back into master. The last thing you want is to pollute your master with non-functioning code from the branch.

Bamboo offers a number of useful tools for tackling branches. This best practice guide explores some of the ways that Bamboo handles branching to improve your development practices.

You may also want to refresh your Git knowledge with the Atlassian Git tutorials page before you read any further.

Best practice approaches
Feature branching with Bamboo plan branches

Objectives and learning outcomes

Understand what feature branching is, and how it can be useful as a development process. After completing this section, you will understand:

1. How feature branching works
2. How feature branches improve quality by eliminating risky merges

What is feature branching?

Feature branching is a lightweight way for a developer to make changes to a software project without having to worry about sharing those changes if they are uncompleted.

The main reasons to use feature branching are to ensure accurate conflict mitigation and to reduce the possibility of pushing code into the master branch or to other people until you are ready to do so. Utilizing rapid, regular code merges assists in reducing code drift across the development process.

Bamboo uses a concept called plan branches to help teams easily test branches using continuous integration and to avoid "merge hell".

Example scenario

Let's examine the following scenario for traditional feature branching:

1. A developer assigns an issue to themselves and creates a new branch (the feature branch) from master.
2. The developer works on the code, makes regular local commits to the feature branch, reaches a finishing point and pushes the commits to the repository.
3. When the issue is completed, the feature branch is merged back into master.

So, what's wrong with this? The developer hasn't run their builds on the feature branch and it is unknown whether the tests pass or not and any defective code from the feature branch will reach the rest of the team when it's merged to master.

Now let's see how it works using Jira and Bamboo plan branches:

1. A developer assigns the issue to themselves in Jira and creates a new branch from master. The name of the branch starts with the issue key so that it can be easily identified and tracked by both Bamboo and Jira.
2. Bamboo detects the new feature branch and creates a new plan branch. A plan branch is created automatically for any build that has plan branching enabled.
3. The developer works on the code, makes regular local commits and pushes the commits to the repository.
4. Bamboo identifies the changes and builds the corresponding plan branch.
5. Optionally, to ensure that the branch and master will work together when merged, Bamboo can then merge the contents of master (including any new changes the team has made) into the the feature branch and have the build run.
6. If the tests pass, Bamboo pushes the updated feature branch back to the repository.
7. When the issue is completed, the feature branch is merged back into master with the knowledge that their new feature will not break on master.

We can already see that the Bamboo plan branch helps us by running build plan tests against the newly merged code. Only if the tests are passed is the code pushed, which prevents incorporating defective code. If the build fails, the merge is thrown away and the developer is notified.

Extending feature branching

We can usefully extend the concept of feature branching to include an integration branch workflow. This concept mirrors the approach of feature branching in that it also advocates frequent merging. However, it provides an integration branch during development of a particular story. When the story is completed, it is merged into master, but offers two different approaches to working around the integration branch:

1. Some teams merge their code into the integration branch while the story development is in progress; when the story is complete, it is then merged directly into master and closed
2. Other teams may work exclusively around the integration branch during their code development, but will wait until the very end when their stories are tested and validated before merging integration onto master.

Conclusion

Feature branching offers a flexible and accurate conflict mitigation tool for developers. By using frequent and regular code merges, code drift and defective code implementation across the project is minimized. Feature branching works particularly well when developers have permission to toggle auto merging on and off to suit their individual development cycle. And of course, Bamboo provides an ideal environment to give developers access to these permissions.

Approaches to branching

Objectives and learning outcomes

Identify and describe how Bamboo can use feature and plan branches. After completing this section, you will understand:
1. The two mechanisms for merging branched code back into the master branch
2. A high level concept view of the branching process

Overview

Feature (or topic) branches are used to develop new features for an upcoming or future release. A feature branch exists only as long as the feature is being developed, and will eventually be merged back into the development branch.

Plan branches represent a branch in the version control system for development of a specific feature. The plan branch inherits all of the configuration defined by the parent plan, but may be built against any other specified plan. Any new branch created can be automatically built and tested using the same build configuration as that of the parent plan. Alternatively you can override the parent plan and individually configure the branch plan. When the branch succeeds, it is merged back into master.

There are two ways in which plan branches can be merged with the master branch.

Example scenario

Let's consider the following branch scenarios:

Scenario 1: Gatekeeper

The gatekeeper method works in the following way:

1. Both master and feature branch are checked out from the repository
2. Changes are merged into master from the feature branch
3. The build plan is run against the merged code, and held in memory by Bamboo
4. If successful, the merged code is pushed to master

You should use the Gatekeeper strategy when you want to:

1. Automatically merge your feature branch back into the master branch after a successful build of the merged changes
2. Quickly identify when a build of combined changes fails, preventing the feature branch from being merged back into the master branch

Scenario 2: Build Updater

The build updater is an alternative approach where changes flow in the opposite direction. It works in the following way:

1. Both master and a feature branch are checked out from the repository
2. Changes are merged into the plan branch from master
3. The build plan is run against the merged code and held in memory by Bamboo
4. If successful, the merged code is pushed to the feature branch
You should use the Build Updater strategy when you want to:

1. Automatically merge changes from the team’s master branch into your feature branch, either after a successful build of the master branch, or at the start of builds against the feature branch.
2. Get notified when the changes on your feature branch are no longer compatible with the team’s master branch.

Now we know how plan branching works, but how do we implement it using Bamboo? Bamboo actually makes it very easy for us. Let’s have a look at another example:

**Scenario 3: Plan branching in DVCS**

This is a typical high level DVCS plan branching scenario:

**Step 1: Create branch** - Use your version control system’s branching feature to create a new branch in your repository

**Step 2: Branch detection** - Bamboo will auto detect the new branch for Git, Mercurial and SVN. Perforce and CVS users will have to manually create the branch on Bamboo’s behalf. This can be done from the Branches tab in your build plan’s configuration screen.

**Step 3: Plan cloning** - Bamboo automatically clones all plans associated with the repository and connects the clones to the new branch

**Step 4: Configure plan variables** - The configuration of plans pointing to the master branch will be inherited by the plan branches. Jobs, stages, and artifact sharing work exactly as defined in the original plan. Variables, notifications and triggers may be customized for each plan branch. Other configuration options for plan branches include:

   1. Merge strategies (see gatekeeper and build updater above)
   2. Toggling auto cleanup on/off
   3. Branch removal after a defined inactivity period

**Step 5: Branch build** - The feature branch is built in accordance with its triggers. The optional merge strategies are applied at build time.

**Conclusion**

Feature and plan branching offers a range of flexible methods for developers to branch and work on different code segments during the development process. The Gatekeeper and Branch Updater methods allow alternative approaches to branching your code, while plan branching in DVCS allows Bamboo to automatically detect new branches in Git, Mercurial and SVN repositories.

---

**Branching with Jira integration**

**Objectives and Learning Outcomes**

Understand how Jira integration can be used to track development changes branching, and how it improves oversight of a development project. After completing this section, you will understand:
1. What Jira integration is
2. How it can be used to track changes within the code development

Overview

Jira integration in plan branches relies on including a Jira issue key as part of the branch name. Bamboo and Jira work together to ensure that Jira issues are attached to development branches, allowing developers and other interested parties to examine which issue has informed the code development within the branch.

Example Scenario

Let's examine the following scenario for Jira integration:

1. A developer picks up a Jira issue and creates a feature branch for it
2. Bamboo creates a link between the issue and the branch, and all the branch's builds
3. The developer works on the issue, making regular pushes to the feature branch, which are built by the corresponding plan branch/es in Bamboo
4. The Jira issue shows the current build status of the feature branch
5. When work on the feature branch is complete, it can be merged to master manually through the version control system, or automatically, by enabling Bamboo's gatekeeper merge strategy

Why use Jira integration?

By including a related Jira issue as part of the branch name, Bamboo can link the issues to the related builds and to the branch itself. This makes oversight of individual stories much easier:

- Product owners can view the development of user stories from within the Jira issue
- QA can select an artifact for testing from within Jira, and identify which issues have informed its development
- Developers can examine builds and artifacts, and see which Jira issues have informed the development process.

The Jira Bamboo plugin

The Jira Bamboo plugin provides enhanced information sharing between Jira and Bamboo, allowing you to view the status of all builds and branches associated with an issue from within the issue itself. Apart from DVCS and branching, the plugin also surfaces deployment information for issues when Bamboo's deployment projects are used.

Learn more about the Jira Bamboo plugin here.

Conclusion

Jira integration with branching provides an effective mechanism for tracking changes in code development and identifying what issues have informed the process. Jira integration also provides an effective way for interested parties to track progress and locate relevant artifacts.

Bamboo Best Practice - Sharing artifacts

General overview
We've already had a look at techniques such as 'fail fast' and 'artifact promotion' as ways of improving your Bamboo processes in the using stages Best Practice guide, but here we're going to dig a little deeper and look at some ways that you can get artifact sharing to work for you.

- General overview
- Sharing build artifacts with downstream processes
- Sharing artifacts between plans

See also:
- Sharing artifacts between jobs
- Sharing artifacts between build plans
- Sharing artifacts from a build plan to a deployment environment

Best practice approaches

Sharing build artifacts with downstream processes

See Artifact promotion for a description of this technique.

**How do I configure artifact sharing between jobs?**

In Bamboo, artifact sharing between jobs is configured using the Artifacts tab on the plan's configuration:

<table>
<thead>
<tr>
<th>Name</th>
<th>Location</th>
<th>Copy pattern</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bamboo WAR</td>
<td>components/bamboo-web-app/target/</td>
<td>*.war</td>
<td>Unshare</td>
</tr>
</tbody>
</table>

Check out Sharing artifacts between jobs to learn how to configure your Bamboo server to take advantage of artifact sharing between jobs.

Sharing artifacts between plans

**Objective**

Identify and describe how artifact sharing between plans can be achieved

**Learning Outcomes**

After completing this section, you will understand how to share an artifact between plans

**Overview**

We discussed above how we can achieve significant time benefits from capturing and sharing artifacts to downstream processes rather than checking out and compiling each time the artifact is required. Generating an artifact at the top of the development pipeline, and passing it to successive downstream processes also has the benefit of ensuring the integrity of the code is maintained throughout the pipeline, because we know it is the exact same code that we tested earlier on. We also discussed how we can manage passing artifacts within a build plan, but let’s suppose that we want to pass artifacts between two plans? Easy: We use the download artifact task to make the artifact available from one plan to another.

**Example scenario**

Let's consider the following artifact sharing example:

Imagine that we have a build plan that creates and uses an artifact - Artifact A. Now let's suppose that we also have a child plan, and we would like to use Artifact A in this plan for some other purpose. Bamboo doesn't technically allow you to share artifacts between plans (but watch this space), so we can use a work around to get our artifact shared into the child plan: We copy it from the parent plan to a remote
storage location, then use the artifact download task to obtain it for the new plan. **Note:** This approach differs significantly to the process for sharing artifacts between jobs.

**Parent Plan**

**Step 1: Checkout & compile** - We need to check out the relevant code from the repository and compile it into an artifact. Our artifact is now defined and available for use by downstream jobs. Let's give it a name - Artifact A - and specify its location, so downstream jobs can find it, though of course only jobs in downstream stages can consume it.

**Step 2: Testing** - We can use some Fail Fast methodology and run some tests on our artifact before we go any further. We can conduct short and rapid unit tests and longer functional testing on our artifact. But we already know that artifact sharing can be used to increase testing speed in both cases.

**Step 3: Deployment** - When testing is complete, the artifact can be deployed to a QA environment by a consuming job that runs a deployment script against it, but we still need to share it with the child plan.

**Step 4: Copy artifact out** - The final step of this plan is to use a task to copy the artifact out to a remote location such as Nexus or Artifactory, using the applicable Bamboo plugins. Alternatively, simply run a script task to copy the artifact to a remote file server location on your own network.

**Child Plan**

**Step 1: Copy artifact in** - The first step of the child plan is to use a task to copy the artifact in from where the parent plan left it. Depending on the method you used to copy it out, you may require a task that utilizes a Bamboo plugin.

**Step 2: Business as usual** - Now that we have copied the artifact in, we can perform regular Bamboo operations as part of an ongoing build plan. These could be additional tests, or deployments into different environments.

**Extending artifact sharing**

And of course, once we have our artifact neatly stored in remote storage, the artifact download task means that it can associated with any build plans that we may want to run.

**Conclusion**

Artifact sharing is a powerful technique for making single artifacts available. Artifact sharing across plans allows us to make artifacts available for different build plans from one checkout and compile. We know that we will always be using a consistent artifact which reduces the time overhead of multiple checkout and compile steps.

**How do I configure artifact sharing between jobs?**

Artifact sharing between jobs is configured using the artifact downloader task:
Check out Sharing artifacts between build plans to learn how to configure your Bamboo server to take advantage of artifact sharing between plans.

.Bamboo Best Practice - Sharing artifacts v5.14

General overview

How do I configure artifact sharing between jobs?

Artifact sharing between jobs is configured using the artifact downloader task:
Check out Sharing artifacts between build plans to learn how to configure your Bamboo server to take advantage of artifact sharing between build plans.

**Bamboo Best Practice - Using Agents**

**General overview**

We've already had a look at how we can improve Bamboo's efficiency in the Using stages and Sharing artifacts best practice guides, so here we're going to have a look at how we can improve raw build speeds using Bamboo agents.

Let's consider this simple Bamboo scenario:

Imagine a set of plans that we have developed and are queued, awaiting a build agent to become available to execute the build. This is great, and exactly what Continuous Integration is all about, but we notice that certain plans seem to sit and wait consistently longer than others. This has the effect of slowing our progress, and may be felt later down our development streamline. But why is it happening? And what can we do about it?

- **General overview**
- **Best practice approaches**
  - Using remote agents
    - Why use remote agents?
    - Unknown capabilities
    - Adding remote agents
  - Using local agents
    - Why use local agents?
    - Adding local agents
  - Monitoring agents
    - Build Queued Duration
    - Build times plugin
    - Agent utilities plugin

See also:

- Bamboo Best Practice - Using stages
- Bamboo Best Practice - Sharing artifacts
- Bamboo Best Practice - Branching & DVCS
Let’s examine exactly what’s going on.

Each build agent offers a set of capabilities, and each plan will have capability requirements that the that the build agent must meet. These could include a range of executables, tasks and JDKs. Build agents are tailored to match specific plan requirements and as a result not all agents can build all plans. Often, only a small subset of agents will meet all of the requirements for a specific plan. Typically, plans that demonstrate consistently long wait times, are the ones that are waiting for a specific combination of capabilities to become available.

The Build Queued Duration report tells us the average time that a plan sits in the queue until build agents become available to execute it. By examining the report, we can identify which builds are too slow, and also if we are sporting wasted capacity on our systems. So how does this help us, and how can we even out our wait times? Adding required capabilities to a greater number of agents helps to improve parallel builds and even out our build loading. We can achieve this in a number of ways.

**Best practice approaches**

**Using remote agents**

*Why use remote agents?*

Adding popular capabilities to more agents is one way to tackle our wait time problem, however we can also take advantage of remote agents to boost our capabilities. By increasing the number of remote agents to the maximum allowed by our license tier, we can add significant amounts of available build capability which will in turn lead to reduced wait times. We could also consider using elastic agents on AWS.

The following graph shows how adding additional remote agents helped the Bamboo team to reduce build wait times for building Bamboo itself:

![Build Queued Duration](image)

When build wait times approached 27 minutes in late 2011, adding additional remote agents with well defined capabilities reduced wait times to less than 10 minutes. The same is also true when wait times approached 33 minutes - additional remote agents ultimately reduced wait times back to less than 10 minutes.

*Unknown capabilities*

Sometimes remote agents have capabilities that are unknown, so Bamboo will not automatically utilize these when it’s looking for agents for a build. Luckily, even if Bamboo doesn’t know about these capabilities, we can quickly and easily detect them. Simply:

Bamboo admin > Agents > $(AGENT) > Detect Server Capabilities

to identify the capabilities available on a remote agent.

*Adding remote agents*

Add remote agents using the Agents panel of the Bamboo Admin page:

Bamboo admin > Agents > Install remote agent
Agents

An agent is a service that executes Bamboo builds and deployments. You can use this page to view, add and delete agents. You can also use this matrix to determine which agents can execute which build plans.

Local agents

Local agents run on the Bamboo server.

- **Select:** All, None, Idle, Disabled
- **Actions:** Delete, Disable, Enable

<table>
<thead>
<tr>
<th>Agent</th>
<th>Status</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local Agent</td>
<td>idle</td>
<td>View</td>
</tr>
<tr>
<td>Release</td>
<td>idle</td>
<td>View</td>
</tr>
<tr>
<td>Reporting agent</td>
<td>Building - BAM-CPL-JOB1-1314</td>
<td>View</td>
</tr>
</tbody>
</table>

Remote agents

Remote agents run on computers other than the Bamboo server.

- **Select:** All, None, Idle, Disabled
- **Actions:** Delete, Disable, Enable

<table>
<thead>
<tr>
<th>Agent</th>
<th>Status</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent-03-01.buildeng.atlassian.com (2)</td>
<td>idle</td>
<td>View</td>
</tr>
</tbody>
</table>

Learn more about adding additional remote agents in the remote agent installation guide.

Using local agents

**Why use local agents?**

If your license doesn’t allow the addition of any more remote agents, then adding a small number of local agents can also help. A sound strategy is to add one or two local agents in the first instance, then evaluate the effect they have had on your build wait times.

**Remember:** too many local agents can start to impact Bamboo’s performance because local agents run inside the same JVM as Bamboo itself. Unless you have 8 cores and 64GB RAM, ~3 local agents is about as many as you can accommodate comfortably.

**Adding local agents**

Add local agents using the Agents panel of the Bamboo Admin page:

**Bamboo admin > Agents > Add Local Agent**
Agents

An agent is a service that executes Bamboo builds and deployments. You can use this page to view, add and delete agents. You can also use this matrix to determine which agents can execute which build plans.

Local agents

Local agents run on the Bamboo server.

Select: All, None, Idle, Disabled  Action: Delete  Disable  Enable

<table>
<thead>
<tr>
<th>Agent</th>
<th>Status</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local Agent</td>
<td>Idle</td>
<td>View</td>
</tr>
<tr>
<td>Release</td>
<td>Idle</td>
<td>View</td>
</tr>
<tr>
<td>Reporting agent</td>
<td>Building - BAM-CIPL-JOB1-1314</td>
<td>View</td>
</tr>
</tbody>
</table>

Remote agents

Remote agents run on computers other than the Bamboo server.

Select: All, None, Idle, Disabled  Action: Delete  Disable  Enable

<table>
<thead>
<tr>
<th>Agent</th>
<th>Status</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent-03-01.buildeng.atlassian.com (2)</td>
<td>Idle</td>
<td>View</td>
</tr>
</tbody>
</table>

Learn more about adding additional local agents in the Creating a local agent guide.

Monitoring agents

Build Queued Duration

The Build Queued Duration report shows how long each build is spending in the build queue, and is an important tool for evaluating build wait times. The build queued duration report also allows you to compare build wait time between different plans.

You can access the report by clicking Reports > Reports > Build Queued Duration and selecting the appropriate build plan for analysis.

Custom Reports and Statistics

Compare trends between different plans. You can choose the different reports and the plans you wish to compare in the form below.

Build times plugin

Atlassian doesn't provide support for the plugin in any Bamboo version.
The plugin is available only for Bamboo Server in versions 4.0 - 4.4.3.

The Build Times for Bamboo plugin provides a visual representation of the relative build times of each job in a build, as well as which agent each job was built by:

The visualization display can report:

- A bar graph of relative build and queue times of jobs in a build
- Which agent each job ran on
- Each job's status (red or green)
- Jobs that didn't run

The Build Times plugin is an official Atlassian Labs production, and is available from the Atlassian Marketplace.

Learn more, and obtain the plugin here.

**Agent utilities plugin**

The plugin is supported only for Bamboo Server 3.4 - 4.4.8.

The Agent Utilities plugin for Bamboo allows the ability to use Server Notifications to monitor Bamboo Agents. The plugin can be configured to generate notifications when agents:

- Go offline
- Are disabled/enabled
- Have capabilities changed

System Notifications

This page allows you to configure system wide notifications. Recipients will get notified regardless of which plan may have caused an event to happen.

There is currently no Instant Messaging Server or Email Server configured. Bamboo will not send out any notifications. Add an Email Server or add an Instant Messaging Server now.

<table>
<thead>
<tr>
<th>Event</th>
<th>Notification Recipient</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Agents Updated</td>
<td>smith (user)</td>
</tr>
<tr>
<td>Agent Config Updated</td>
<td>smith (user)</td>
</tr>
<tr>
<td>Agent Offline</td>
<td><a href="mailto:agents-alert@mycompany.com">agents-alert@mycompany.com</a> (email address)</td>
</tr>
<tr>
<td></td>
<td>smith (user)</td>
</tr>
</tbody>
</table>

Add System Notification

Select notification event and recipient

Event: Agent Offline
Notification set for any agent that goes offline

Recipient Type: Email Address
Email Address: agents-alert@mycompany.com

Add | Cancel
The Build Times plugin is a third party production by ProNetBeans.com, and is available from the Atlassian Marketplace. Learn more, and obtain the plugin here.

**Bamboo Best Practice v6.0**

Bamboo is a fantastic tool for continuous integration and deployment. It offers a powerful tool for automating software development, however knowledge of some of the tips and tricks that our Bamboo masters use can help reduce friction within your own development cycles.

This user guide has information about how to get the best out of Bamboo, and includes a number of scenarios and best practice approaches. Please see Using Bamboo for more information on specific Bamboo installation, configuration and usage.

Visual Studio

Visual Studio is a complete set of development tools for building ASP.NET Web applications, XML Web Services, desktop applications, and mobile applications. Visual Basic, Visual C#, and Visual C++ all use the same integrated development environment (IDE), which enables tool sharing and eases the creation of mixed-language solutions. In addition, these languages use the functionality of the .NET Framework, which provides access to key technologies that simplify the development of ASP Web applications and XML Web Services.

Integrate Bamboo with Visual Studio
Zephyr

Zephyr’s real-time test management products enable development and QA teams to ship high quality software on time in 100 countries.

BrowserStack

BrowserStack is a cross-browser testing tool, used to extensively test public websites and protected servers, on real mobile and desktop browsers. The infrastructure consists of servers and mobile device cloud across the globe which can be used for interactive, Selenium and JavaScript testing.

Integrate Bamboo with BrowserStack

GitLab

GitLab is a web-based Git repository manager with wiki and issue tracking features, using an open source license, developed by GitLab Inc.

Integrate Bamboo with GitLab

JFrog

JFrog provides solutions to automate software package management from development to distribution. JFrog Artifactory is an artifact repository manager that fully supports software packages created by any language or technology. JFrog Bintray gives developers full control over how they store, publish, download, promote and distribute software with advanced features that automate the software distribution process. With JFrog, build managers can push their build info and artifacts directly to Artifactory and Bintray.
Octopus Deploy

Octopus is a deployment and automation tool that works with your build server to enable reliable, secure, automated releases of ASP.NET applications and Windows Services into test, staging and production environments, whether they are in the cloud or on-premises.

Integrate Bamboo with Octopus Deploy

Sauce Labs

Sauce Labs provides a cloud based platform for the automated testing of web and mobile applications. Optimized for Continuous Integration (CI) and Continuous Delivery (CD), Sauce Labs eliminates the time and expense of maintaining an in house testing infrastructure, freeing development teams of any size to innovate and release better software, faster.

Integrate Bamboo with Sauce Labs

Sonatype

With more than 100,000 installations, companies around the globe use Sonatype's Nexus solutions to manage reusable components and improve the security, quality and speed of their software supply chains.

Integrate Bamboo with Sonatype

SourceClear

SourceClear provides automatic vulnerability detection for your open source dependencies that fits perfectly into your workflow. Detection is available for Java, Python, Ruby, Node, and JavaScript projects.

Integrate Bamboo with SourceClear

Administering Bamboo

Bamboo is a continuous integration (CI) and deployment server. Bamboo assists software development teams by providing:

- automated building and testing of software source-code status.
- updates on successful/failed builds.
- reporting tools for statistical analysis.
- visibility into, and control over, release artifacts and environments.

This administration guide has information about managing the Bamboo server itself. Please see Using Bamboo for help with setting up CI builds and deployments.

Administrator

System settings

You can view system information for Bamboo from the administration console.

The system information contains useful data for you to send to Atlassian when requesting support.

See Locating important directories and files for more information.

Viewing your Bamboo system information

1. Click the icon in the Bamboo header and choose Overview.
2. Click System Information (under 'System') in the left navigation panel.

Screenshot: Bamboo system information (cropped)
System properties

System date: Tuesday, 07 Jan 2014
System time: 10:10:18
Up time: 14 minutes, 28 seconds (since Tue Jan 07 09:55:49 EST 2014)
Username: atlassian
User timezone: Australia/Sydney
User locale: English (United States)
System encoding: MacRoman
Operating system: Mac OS X 10.8.5
Operating system architecture: x86_64
Available processors: 8
Application server: Apache Tomcat/6.0.33

Java / JVM information

Java version: 1.6.0_65
Java vendor: Apple Inc.
JVM spec. version: 1.0
JVM spec. vendor: Sun Microsystems Inc.
JVM version: 20.65-b04-462
JVM vendor: Apple Inc.
JVM name: Java HotSpot(TM) 64-Bit Server VM

Configuring system settings

For information on configuring system settings, see the following topics:

- Updating your Bamboo license details
- Specifying Bamboo's title
- Specifying Bamboo's URL
- Logging in Bamboo
- Enabling GZIP compression
- Enabling Bamboo's Remote API
- Starting Bamboo
- Configuring your system properties
- Configuring Gravatar support
- Tracking changes to your Bamboo server

Updating your Bamboo license details

When you upgrade or renew your Bamboo license, you will receive a new license key. You will need to update your Bamboo server with the new license key.

Please see the Licensing FAQ if you have questions to do with licensing.

### Related pages:
- System settings

To update your Bamboo license key:

1. Click the icon in the Bamboo header and choose Overview.
2. Click License Details (under 'System') in the left navigation panel. This will display your existing Bamboo license details.
3. Paste your new license into License Key.
4. Click Save New License.

Specifying Bamboo's title

Bamboo's name is the displayed title of this installation of Bamboo. It will appear throughout Bamboo (e.g. on the Dashboard), and in the window title of your users' browsers.

### Related pages:
- System settings

To specify Bamboo's title:

1. Click the icon in the Bamboo header and choose Overview.
2. Click General Configuration (under 'System') in the left navigation column.
3. Type the display title for your Bamboo server (e.g. "MyCompany's Bamboo") into the Name field.
4. Click Save.

Specifying Bamboo's URL

This is the base URL of this installation of Bamboo. All links created (for links in Bamboo email notifications etc.) will be prefixed by this URL.

### To specify Bamboo's URL:

1. Click the icon in the Bamboo header and choose Overview.
2. Click General Configuration (under 'System'), in the left navigation panel.
3. In the Base URL field, type the URL address of your Bamboo server (for example, "http://keg:8080/bamboo").
4. Click Save.

### Related pages:
- System settings

Notes

- Accessing Bamboo from Outside a Firewall — When accessing Bamboo through a web browser, most Bamboo URL links (which provide navigation throughout the product) will use the base URL that was originally entered into your browser's URL field. For example, to access Bamboo through a web browser on the same machine running Bamboo itself, you may have entered the base URL:
Logging in Bamboo

Bamboo generates the following sets of logs:

**Build logs**

The build logs are generated each time a plan is executed. All information specific to the build is stored in these logs, which can be downloaded as an artifact (see **Viewing a build’s artifacts**). You cannot change the logging configuration for the build logs.

The build logs are located in the `<Bamboo-Home>/xml-data/builds/` sub-directories.

---

**Bamboo server logs**

Bamboo records all server activity in the `atlassian-bamboo.log`. The location of the `atlassian-bamboo.log` file can be viewed in Bamboo’s **System Information** under the ‘Bamboo Paths’ section.

In case of a Tomcat webapp deployment, the logs are piped out to `catalina.out` file.

**atlassian-bamboo logs for elastic agents**

Elastic agent activity is logged inside the elastic instance where the elastic agent runs. To access the elastic agent logs (`atlassian-bamboo.log` and `bamboo-elastic-agent.out`) use `ssh` to log in to your elastic instance as described in **Viewing an elastic instance** and retrieve the logs.

**atlassian-bamboo logs for remote agents**

All agent activity is recorded in `atlassian-bamboo-agent.log` file stored on the agent machine. These are generated in the running directory of the agent. The running directory can be viewed in the **remote agent’s system properties** under the ‘Bamboo Paths’ section.

See [Locating important directories and files](#) for information on where to find other important files in Bamboo.

---

**Configuring the level of logging on the Bamboo server**

Bamboo uses the `log4j` library for logging during runtime. The logging levels can be changed by editing the `<Bamboo-Install>/atlassian-bamboo/WEB-INF/classes/log4j.properties` file. There are five logging levels available: `DEBUG`, `INFO`, `WARN`, `ERROR` and `FATAL`. Each logging level provides more logging information that the level after it:

```
DEBUG > INFO > WARN > ERROR > FATAL
```

i.e. `DEBUG` provides the most verbose logging and `FATAL` provides the least verbose logging.

You can adjust the logging levels for the different Bamboo packages on the fly, using the runtime `log4j` configuration tool in the Bamboo administration console. The default log settings are still stored in the `log4j.properties` file. When you view the log settings page for the first time you will see the default log settings as defined in `log4j.properties`. All changes to the log settings via the runtime `log4j` configuration tool **will not be persisted** and are valid during Bamboo runtime only.

Before you begin:

- Note, you do not need to restart your Bamboo server for any logging changes to take effect.

**Change the level of logging on your Bamboo server**

1. Click the `≡` icon in the Bamboo header and choose **Overview**.
2. Click Log Settings (under ‘System’) in the left navigation panel. The ‘Bamboo Log Settings’ page will display showing the Bamboo packages being logged (see screenshot below).

   - To change the logging level of a package that is already being logged, locate the Bamboo package, select the desired logging level from the list next to it and click Save.
   - To start monitoring a package in the Bamboo logs, enter the class name in the text box at the top of the page, select the desired logging level from the list next to it and click Add.
   - To stop logging a package, locate the Bamboo package and click Delete next to it.

_Screenshot: Bamboo log settings_

### Configuring the level of logging on remote agents

The runtime log4j configuration tool in the Bamboo administration console can only be used to modify the logging levels for the Bamboo server. To configure the logging levels for your remote agents, you will need to update the `log4j.properties` file manually.

You can control the logging for each of remote agents separately from the Bamboo server. To do this, simply repeat the process described below for multiple remote agents, so that each remote agent has a `log4j.properties` file that overrides the `log4j.properties` file on the Bamboo server.

**Change the level of logging on your remote agent**

1. Configure a `log4j.properties` file for your remote agent. This can be any `log4j.properties` file. If you do not already have a `log4j.properties` file, you can take a copy of the `log4j.properties` file from the server, copy it to your remote agent and configure it as desired.

   _log4j.properties file example:_

   ```properties
   # Example log4j.properties file
   log4j.rootLogger=INFO, console
   log4j.appender.console=org.apache.log4j.ConsoleAppender
   log4j.appender.console.layout=org.apache.log4j.PatternLayout
   log4j.appender.console.layout.ConversionPattern=%d{ISO8801} %-5p %c{1}:%L - %m%n
   ```
log4j.rootLogger=INFO, console
log4j.appender.console=org.apache.log4j.ConsoleAppender
log4j.appender.console.layout=org.apache.log4j.PatternLayout
log4j.appender.console.layout.ConversionPattern=%d %p [%t] [%c{1}]%m%n
log4j.category.com.atlassian.bamboo=DEBUG

**The `rootLogger` property in the `log4j.properties` file controls the verbosity of logs being generated at the top level.** By default, the root level logging is set to 'INFO'. To change the root level logging, find the following lines in `<Bamboo-Install>/webapp/WEB-INF/classes/log4j.properties` file and update the value of `log4j.rootLogger` to the desired logging level:

```
# Change the following line to configure the bamboo logging levels (one of INFO, DEBUG, ERROR, FATAL)
#
log4j.rootLogger=INFO, console, filelog
```

- Modify the logging level for any of the individual packages in the `log4j.properties` as desired, e.g. `log4j.category.webwork=WARN`

2. Save changes to the file.
3. Update the `log4j.configuration` system property on your remote agent to point to the `log4j.properties` file. To do this, add the following line to the `<bamboo-agent-home>/conf/wrapper.conf` file:

   `wrapper.java.additional.3=-Dlog4j.configuration=/full/path/to/log4j.properties`

   where `/full/path/to/log4j.properties` is the absolute path of your `log4j.properties` file.
4. Restart your remote agent.

### Configuring the location of the atlassian-bamboo logs

To change the directory that the atlassian-bamboo logs are generated to, you must set the environment variable for the target location of the logs, as seen below:

```
log4j.appender.fileLog.file=/my/path/to/atlassian-bamboo.log
```

Note that the new log file location applies to both the server and remote agents. If using an absolute path this may result in aggregated logs.

### Enabling GZIP compression

You can enable GZIP compression in order to reduce the size of Bamboo's web pages. This is useful if Bamboo is being run over slow networks. There is a slight performance penalty, and note that GZIP may not work for languages other than English.

**Related pages:**
- System settings

To enable GZIP compression:

1. Click the icon in the Bamboo header and choose Overview.
2. Click General Configuration (under 'System') in the left navigation panel.
3. Select Apply gzip compression to reduce the size of Bamboo's web pages?.
4. Click Save.

### Enabling Bamboo's Remote API

Please note, the Bamboo Remote API has been deprecated in favor of the new Bamboo REST API.

You can access Bamboo's data from an external program by using Bamboo's REST-style remote API.
Starting Bamboo

Configuring Bamboo system properties

The default settings on a number of Bamboo functions can be configured by setting the appropriate system properties.

Bamboo on UNIX-based operating systems (such as Solaris, Linux or Mac OS X) can be started by using the `setenv.sh` script.

Bamboo on Windows-based operating systems can be started by running the `setenv.bat` file from the command line (which is the same as running the 'Start in Console' option from the Windows Start menu) or as a Windows Service.

On this page:
- Configuring Bamboo system properties

Related pages:
- System settings

Please see Configuring your system properties for more information on configuring your Bamboo system properties.

Configuring your system properties

This page describes how to set Java properties and options on startup for Bamboo.

On this page:
- Linux
- Windows (starting from .bat file)
- Windows service
- Changing the Bamboo start port
- List of startup parameters

Linux

To configure system properties in Linux installations

1. From `<bamboo-install>/bin`, open `setenv.sh`.
2. Find the section `JVM_SUPPORT_RECOMMENDED_ARGS=`
3. Refer to the list of parameters below.

   Add all parameters in a space-separated list, inside the quotations.

Windows (starting from .bat file)

To configure system properties in Windows installations when starting from the .bat file

1. From `<bamboo-install>/bin`, open `setenv.bat`.
2. Find the section `set JVM_SUPPORT_RECOMMENDED_ARGS=`
3. Refer to the list of parameters below.

   Add all parameters in a space-separated list, inside the quotations.

Windows service

There are two ways to configure system properties when starting Bamboo as a service, either via the command line or in the Windows
Setting properties for Windows services from the command line

1. Identify the name of the service that Bamboo is installed as in Windows (Control Panel > Administrative Tools > Services):

   [Image of service properties]

   - Service name: Bamboo
   - Display name: Apache Tomcat Bamboo
   - Description: Atlassian Bamboo Server - http://localhost:8085/
   - Path to executable: C:\Program Files\Bamboo\bin\tomcat8w.exe
   - Startup type: Automatic

   You can specify the start parameters that apply when you start the service from here:

   Service status: Stopped
   Start Stop Pause Resume
   Start parameters:

   2. Open a command prompt from Start > Run > type 'cmd' > Enter.
   3. Change directory to the bin directory of your Bamboo installation directory.
   4. Run:

   ```
   tomcat8w //ES//%SERVICENAME%
   ```

   *In the above example, it would be tomcat8w //ES//Bamboo*

   5. Click on the Java tab to see the list of current start-up options:
6. Append any new option on its own new line by adding to the end of the existing Java Options. Refer to the list of parameters below.

If you want to change the heap size configured for the JVM, use the Initial memory pool and Maximum memory pool fields instead of adding the -Xms and -Xmx parameters to the list of Java options.

**Setting properties for Windows services using the Windows registry**

In some versions of Windows, there is no option to add Java variables to the service. In these cases, you must add the properties by viewing the option list in the registry.

To set properties for Windows services using the Windows registry

1. Go to Start > Run, and run "regedit32.exe".

2. Find the Services entry:
   
   **32-bit**: HKEY_LOCAL_MACHINE >> SOFTWARE >> Apache Software Foundation >> Procrun 2.0 >> Bamboo
   
   **64-bit**: HKEY_LOCAL_MACHINE >> SOFTWARE >> Wow6432Node >> Apache Software Foundation >> Procrun 2.0 >> Bamboo
3. To change existing properties, especially increasing Xmx memory, double-click the appropriate value.

4. To change additional properties, double-click options.

5. Refer to the list of parameters below. Enter each on a separate line.

Changing the Bamboo start port

1. Stop Bamboo.
2. Edit `<Bamboo install directory>/conf/server.xml`
3. Update the following so that `Connector port` is set to the port value you require:

```
<Service name="Catalina">
  <Connector port="8085"
    maxThreads="150"
    minSpareThreads="25"
    connectionTimeout="20000"
    enableLookups="false"
    maxHttpHeaderSize="8192"
    protocol="HTTP/1.1"
    useBodyEncodingForURI="true"
    redirectPort="8443"
    acceptCount="100"
    disableUploadTimeout="true"/>
```

4. Restart Bamboo.

Configuring your system properties v5.14

This page describes how to set Java properties and options on startup for Bamboo.

On this page:
- Linux
- Windows (starting from .bat file)
- Windows service
- Changing the Bamboo start port
- List of startup parameters

**Linux**

To configure system properties in Linux installations

1. From `<bamboo-install>/bin`, open `setenv.sh`
2. Find the section `JVM_SUPPORT_RECOMMENDED_ARGS=`
3. Refer to the list of parameters below.

Add all parameters in a space-separated list, inside the quotations.

**Windows (starting from .bat file)**

To configure system properties in Windows installations when starting from the .bat file

1. From `<bamboo-install>/bin`, open `setenv.bat`
2. Find the section `set JVM_SUPPORT_RECOMMENDED_ARGS=`
3. Refer to the list of parameters below.

Add all parameters in a space-separated list, inside the quotations.

**Windows service**

There are two ways to configure system properties when starting Bamboo as a service, either via the command line or in the Windows registry.

Setting properties for Windows services from the command line

1. Identify the name of the service that Bamboo is installed as in Windows (Control Panel > Administrative Tools > Services):
2. Open a command prompt from Start > Run > type ‘cmd’ > Enter.
3. Change directory to the bin directory of your Bamboo installation directory.
4. Run:

    tomcat8w //ES//%SERVICENAME%

In the above example, it would be tomcat8w //ES//Bamboo

5. Click on the Java tab to see the list of current start-up options:
6. Append any new option on its own new line by adding to the end of the existing Java Options. Refer to the list of parameters below.

**Warning:** If you want to change the heap size configured for the JVM, use the **Initial memory pool** and **Maximum memory pool** fields instead of adding the `-Xms` and `-Xmx` parameters to the list of Java options.

**Setting properties for Windows services using the Windows registry**

In some versions of Windows, there is no option to add Java variables to the service. In these cases, you must add the properties by viewing the option list in the registry.

**To set properties for Windows services using the Windows registry**

1. Go to **Start > Run**, and run "regedit32.exe".

2. Find the Services entry:
   - **32-bit:** `HKEY_LOCAL_MACHINE >> SOFTWARE >> Apache Software Foundation >> Procrun 2.0 >> Bamboo`
   - **64-bit:** `HKEY_LOCAL_MACHINE >> SOFTWARE >> Wow6432Node >> Apache Software Foundation >> Procrun 2.0 >> Bamboo`
3. To change existing properties, especially increasing Xmx memory, double-click the appropriate value.

4. To change additional properties, double-click options.

5. Refer to the list of parameters below. Enter each on a separate line.

**Changing the Bamboo start port**

1. Stop Bamboo.
2. Edit `<Bamboo install directory>/conf/server.xml`
3. Update the following so that `Connector port` is set to the port value you require:

   ```xml
   <Service name="Catalina">
   <Connector port="8085">
      maxThreads="150"
      minSpareThreads="25"
      connectionTimeout="20000"
      enableLookups="false"
      maxHttpHeaderSize="8192"
      protocol="HTTP/1.1"
      useBodyEncodingForURI="true"
      redirectPort="8443"
      acceptCount="100"
      disableUploadTimeout="true"
   </Connector>
   </Service>
   ```

4. Restart Bamboo.

### Configuring Gravatar support

Bamboo is configured to support Gravatars by default. This means that Bamboo will attempt to use user’s emails to retrieve profile pictures from the Gravatar service. The profile pictures will be displayed against user activity, e.g. comments, in Bamboo.

**Related pages:**
- System settings

#### Enabling Gravatar support:

1. Click the 
   ![icon](image-url)
   icon in the Bamboo header and choose **Overview**.
2. Click **General Configuration** in the left navigation panel
3. Select the **Enable Gravatar Support** checkbox
4. Enter the URL of your Gravatar server in the URL field, or leave as default if you wish to use the default Gravatar service
5. Click **Save**.

#### Disabling Gravatar support:

1. Click the 
   ![icon](image-url)
   icon in the Bamboo header and choose **Overview**.
2. Click **General Configuration** in the left navigation panel
3. Uncheck the **Enable Gravatar Support** checkbox
4. Click **Save**.

### Tracking changes to your Bamboo server

#### Tracking configuration changes

You can track changes to the configuration of your Bamboo server, as well as track changes to any plans it may be running.

To track changes, you must enable Audit logging. To enable Audit logging:

1. Click the 
   ![icon](image-url)
   icon in the Bamboo header and choose **Overview**.
2. Select **Audit Log** (under 'System') in the left navigation column.
3. Select **Enable audit logging**

The Audit log will record details of changes made to the configuration of the Bamboo server. It will record:

- the time and date
- the user
- the changed field
- the old value and
- the new value

The Audit log does not record change of permissions.

Audit logging will also record details of changes made to any plans, including:

- Plan branch creation
- Plan deletion
Deleting Audit Logs

You may wish to delete audit logs, particularly when the plans or configuration changes have expired.

To delete your configuration change history, select **Delete all global audit logs**.

To delete all audit logs, including any plan audit logs, select **Delete all audit logs**.

**Screenshot: Audit logging**

**Screenshot: Audit logging**

You can define the following capabilities for an agent:

- an executable (e.g. Maven)
- a JDK
- a Version Control System client application (e.g. Git)
- a custom capability. This is a key-value property which defines a particular characteristic of an agent (e.g. 'operating.system=WindowsXP' or 'fast.builds=true').

Capabilities typically define the path to an executable that has already been installed, and must be defined in Bamboo before Bamboo or its agents can make use of those.

Capabilities can be defined specifically for an agent, or they can be shared between all remote agents. Note that the value of an agent-specific capability overrides the value of a shared capability of the same name (if one exists).

See also:

- Configuring capabilities
- Viewing a capability’s agents and jobs
- About capabilities and requirements

**Viewing the agents and plans related to a capability**

To view the agents and plans related to a capability, see **Viewing a capability's agents and jobs**.

**Configuring agents**

A Bamboo agent is a service that can run job builds. There are the following types of Bamboo agents:

- local agents run as part of the Bamboo server.
- remote agents run on computers, other than the Bamboo server, that run the remote agent tool.
- elastic agents run in the Amazon Elastic Compute Cloud (EC2).

Local agents run in the Bamboo server's process, i.e. in the same JVM as the server. Each remote agent runs in its own process, i.e. has its own JVM.

Each agent has a defined set of capabilities and can only run builds for jobs whose requirements match the agent's capabilities.

If you are looking for information on elastic agents, please refer to the documentation on Working with Elastic Bamboo.

On this page:
- Creating a new agent
- Configuring an agent's capabilities
- Disabling or deleting an agent
- Notes

Creating a new agent

To create a new agent, see:
- Creating a local agent, or
- Creating a remote agent.

Configuring an agent's capabilities

To configure an existing agent's capabilities, see:
- Configuring capabilities
- Configuring remote agent capabilities

Disabling or deleting an agent

To disable or delete an agent, see Disabling or deleting an agent.

Notes

- A capability is a feature of an agent. A capability can be defined on an agent for:
  - an executable (e.g. Maven)
  - a JDK
  - a Version Control System client application (e.g. Git)
  - a custom capability. This is a key-value property which defines a particular characteristic of an agent (e.g. 'operating.system=WindowsXP' or 'fast.builds=true').

  Capabilities typically define the path to an executable that has already been installed, and must be defined in Bamboo before Bamboo or its agents can make use of those.

  Capabilities can be defined specifically for an agent, or they can be shared between either all local agents or all remote agents. Note that the value of an agent-specific capability overrides the value of a shared capability of the same name (if one exists).

Viewing a Bamboo agent's details

A Bamboo agent is a service that can run job builds. There are the following types of Bamboo agents:

- local agents run as part of the Bamboo server.
- remote agents run on computers, other than the Bamboo server, that run the remote agent tool.
- elastic agents run in the Amazon Elastic Compute Cloud (EC2).

Local agents run in the Bamboo server's process, i.e. in the same JVM as the server. Each remote agent runs in its own process, i.e. has its own JVM.

Each agent has a defined set of capabilities and can only run builds for jobs whose requirements match the agent's capabilities.

Viewing an agent's details

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
To view an agent's details:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Agents in the left panel to display the 'Agents' page, which lists all local and remote agents that currently exist in your Bamboo system.
3. Click the name of the desired agent. The agent's page will be displayed.
4. Click one of the following tabs to see corresponding details for the agent:

   **Capabilities**
   Displays a list of all agent-specific and shared capabilities. The capabilities in each of those sections are grouped into the following subsections:
   - Custom — custom capabilities.
   - Executable — executable capabilities.
   - JDK — JDK capabilities.
   - Perforce, Mercurial, Git — VCS capability.
   - You'll only see a subsection if a capability of that type is defined in Bamboo. To define a new capability, see Configuring capabilities.

   **Executable jobs**
   Displays a list of jobs, arranged by plan, that the agent can build.

   **System properties**
   Displays information about the agent.

   **Audit logs**
   Displays a record of changes that have been made to the agent.

---

**Viewing the agents that can build jobs**

To view which agents can build which jobs:
1. Click the ![icon](image)
   icon in the Bamboo header and choose **Overview**.
2. Click **Agent Matrix** in the left navigation panel.

**Editing an agent’s name or description**

To edit an agent’s name or description:

1. Navigate to the desired agent, as described above.
2. Click **Edit Details**.
3. Update the details for the agent.
4. Click **Save**.

**Viewing a Bamboo agent’s details v5.14**

Viewing a Bamboo agent's details v6.1

A Bamboo **agent** is a service that can run **job builds**. There are the following types of Bamboo agents:

- **local agents** run as part of the Bamboo server.
- **remote agents** run on computers, other than the Bamboo server, that run the remote agent tool.
- **elastic agents** run in the Amazon Elastic Compute Cloud (EC2).

Local agents run in the Bamboo server's process, i.e. in the same JVM as the server. Each remote agent runs in its own process, i.e. has its own JVM.

Each agent has a defined set of **capabilities** and can only run builds for jobs whose **requirements** match the agent's capabilities.
### Viewing an agent's details

#### To view an agent's details:

1. Click the icon in the Bamboo header and choose **Overview**.
2. Click **Agents** in the left panel to display the 'Agents' page, which lists all local and remote agents that currently exist in your Bamboo system.
3. Click the name of the desired agent. The agent's page will be displayed.
4. Click one of the following tabs to see corresponding details for the agent:

   - **Capabilities**
     Displays a list of all agent-specific and shared capabilities. The capabilities in each of those sections are grouped into the following subsections:
     - Custom — custom capabilities.
     - Executable — executable capabilities.
     - JDK — JDK capabilities.
     - Perforce, Mercurial, Git — VCS capability.
     You'll only see a subsection if a capability of that type is defined in Bamboo. To define a new capability, see **Configuring capabilities**.

   - **Executable jobs**
     Displays a list of jobs, arranged by plan, that the agent can build.

   - **System properties**
     Displays information about the agent.

   - **Audit logs**
     Displays a record of changes that have been made to the agent.
Viewing the agents that can build jobs

To view which agents can build which jobs:

1. Click the icon in the Bamboo header and choose **Overview**.
2. Click **Agent Matrix** in the left navigation panel.

Editing an agent's name or description

To edit an agent's name or description:

1. Navigate to the desired agent, as described above.
2. Click **Edit Details**.
3. Update the details for the agent.
4. Click **Save**.

Creating a local agent

A Bamboo agent is a service that can run job builds. There are the following types of Bamboo agents:

- **local agents** run as part of the Bamboo server.
- **remote agents** run on computers, other than the Bamboo server, that run the remote agent tool.
- **elastic agents** run in the Amazon Elastic Compute Cloud (EC2).

Local agents run in the Bamboo server's process, i.e. in the same JVM as the server. Each remote agent runs in its own process, i.e. has its own JVM.

Each agent has a defined set of capabilities and can only run builds for jobs whose requirements match the agent's capabilities.

Note that one local agent, with the default name of 'Default Agent', is automatically created after installing Bamboo.
To create a new local agent:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Agents in the left panel (under 'Build Resources') to display a list of all local and remote agents that currently exist in your Bamboo system.
3. Click Add Local Agent.
4. Enter details for the agent. The name is displayed on the dashboard. The description is only visible to administrators.
5. Click Add.

Note that your new local agent:
- will be enabled by default.
- will inherit all local server capabilities that are defined in your Bamboo system.
- will be able to run builds for all jobs whose requirements are met by the agent's capabilities (see Configuring a job's requirements).

### Add local agent

Enter a new unique name and a description for this local agent.

**Information**

- **Name**
- **Description**

[Add Cancel]

---

### Disabling or deleting an agent

Bamboo allows you to disable or delete an agent, to prevent that agent from running any further builds.

- **Disabling an agent** lets you keep the agent in Bamboo, but stops it from running builds.
  - If you need to prevent Bamboo from building any plans at all (e.g. while you re-index Bamboo), you can disable all agents. By doing so, all builds will wait in the queue until you re-enable the agents.
  - Deleting an agent removes it from Bamboo altogether. If you need to use the agent again in future, you will need to recreate it (see Creating a local agent and Creating a remote agent for more information).

Note that you can also delete/disable individual plans and/or their jobs. This prevents the plans and/or their jobs from being submitted to the build queue. See Disabling or deleting a plan and Disabling or deleting a job.

**Related pages:**

- Disabling or deleting a plan
- Disabling or deleting a job
- Creating a remote agent
  - Creating a local agent

---

To disable (or delete) an agent:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Agents in the left panel to display the 'Agents' screen, which lists all agents that currently exist in your Bamboo system. The 'Status' column indicates which agents are currently enabled or disabled. Scroll down if you require remote agents.
3. Select the check box for the agent (or agents) you wish to disable or delete.
4. Click the Disable (or Delete) button above the table.

**Screenshot: Agent — Delete or Disable Remote agent**
Dedicating an agent

Bamboo allows you to dedicate an agent, to run, for example, only specific build projects, deployment projects or associated activities. You must dedicate an agent to a type of activity and a specific entity of that type.

Note that when you dedicate an agent, then no other activity will be able to use it, unless it is dedicated to that activity as well. Similarly, no other agent will be able to build this plan other than the agent(s) that are dedicated to build it.

Related pages:
- Disabling or deleting an agent

To dedicate an agent:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Agents in the left panel to display the ‘Agents’ screen. This displays all local and remote agents currently available to your Bamboo system. The ‘Status’ column indicates which agents are currently enabled or disabled.
3. Click Image configurations for EC2 elastic agents.
4. Select the agent you wish to dedicate, and click on the Dedicate agent tab.
5. Using the menu, select the type of activity you wish to dedicate the agent to. Available choices are:
   - Build project
   - Build plan
   - Build job
   - Deployment project
   - Deployment environment
6. Select an entity to assign the dedicated agent to. This will be a specific project, plan, job or environment. Use the menu or type-ahead field to locate a suitable entity.
7. If required, click Add to add an additional entity dedication.
8. Click Save to dedicate your agent.

Monitoring agent status

You can monitor your agents’ status to check that all agents are functioning as expected.

Online versus Offline agents:

- An ‘Online’ agent is an agent which is currently available for use by Bamboo. Local agents are always online, although remote agents may be either online or offline.
An ‘Offline’ agent is a remote agent which has been registered with the Bamboo server, was online, but is now unavailable for builds because:

- The Bamboo remote agent process (running on the remote hardware) was stopped.
- The Bamboo server (for whatever reason) cannot communicate with the remote hardware that is running the Bamboo remote agent process.

Bamboo administrators can manually 'disable' an online agent to prevent it from being used in build generation. The agent will still be online and it can be 'enabled' at a later point in time. It is not possible to disable offline agents.

To monitor the status of your agents:

1. Click the icon in the Bamboo header and choose Overview.

2. Click Agents in the left panel. This will display the 'Agents' screen, showing lists of all local agents and all remote agents that currently exist in your Bamboo system (see screenshot below).

Agents can have one of the following statuses:

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Idle</td>
<td>Available to execute builds.</td>
</tr>
<tr>
<td>Building</td>
<td>Currently executing a build.</td>
</tr>
<tr>
<td>Canceling</td>
<td>Currently canceling a Job build.</td>
</tr>
<tr>
<td>Disabled</td>
<td>Not available to execute builds (see Disabling or deleting an agent).</td>
</tr>
<tr>
<td>Disabled - Building</td>
<td>Currently executing a build, but disabled so cannot execute further builds.</td>
</tr>
<tr>
<td>Disabled - Canceling</td>
<td>Currently canceling a build, and disabled so cannot execute further builds.</td>
</tr>
</tbody>
</table>

Note that to see the jobs that are currently being built, look at the Current Activity tab on the dashboard.

You can monitor your agents' status to check that all agents are functioning as expected.

Online versus Offline agents:

- An 'Online' agent is an agent which is currently available for use by Bamboo. Local agents are always online, although remote agents may be either online or offline.
- An 'Offline' agent is a remote agent which has been registered with the Bamboo server, was online, but is now unavailable for builds because:
  - The Bamboo remote agent process (running on the remote hardware) was stopped.
  - The Bamboo server (for whatever reason) cannot communicate with the remote hardware that is running the Bamboo remote agent process.

Bamboo administrators can manually 'disable' an online agent to prevent it from being used in build generation. The agent will still be online and it can be 'enabled' at a later point in time. It is not possible to disable offline agents.

To monitor the status of your agents:

1. Click the icon in the Bamboo header and choose Overview.

2. Click Agents in the left panel. This will display the 'Agents' screen, showing lists of all local agents and all remote agents that currently exist in your Bamboo system (see screenshot below).

Agents can have one of the following statuses:

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Idle</td>
<td>Available to execute builds.</td>
</tr>
<tr>
<td>Building</td>
<td>Currently executing a build.</td>
</tr>
<tr>
<td>Canceling</td>
<td>Currently canceling a Job build</td>
</tr>
</tbody>
</table>
Note that to see the jobs that are currently being built, look at the **Current Activity** tab on the **dashboard**.

### Monitoring agent status v6.1

You can monitor your agents' status to check that all agents are functioning as expected.

#### Online versus Offline agents:

- An 'Online' agent is an agent which is currently available for use by Bamboo. Local agents are always online, although remote agents may be either online or offline.
- An 'Offline' agent is a remote agent which has been registered with the Bamboo server, was online, but is now unavailable for builds because:
  - The Bamboo remote agent process (running on the remote hardware) was stopped.
  - The Bamboo server (for whatever reason) cannot communicate with the remote hardware that is running the Bamboo remote agent process.

Bamboo administrators can manually 'disable' an online agent to prevent it from being used in build generation. The agent will still be online and it can be 'enabled' at a later point in time. It is not possible to disable offline agents.

**Related pages:**
- Bamboo remote agent installation guide

#### To monitor the status of your agents:

1. Click the ![icon](image) in the Bamboo header and choose **Overview**.
2. Click **Agents** in the left panel. This will display the ‘Agents’ screen, showing lists of all local agents and all remote agents that currently exist in your Bamboo system (see screenshot below).

Agents can have one of the following statuses:

- **Idle**
  - Available to execute builds.
- **Building**
  - Currently executing a build.
- **Canceling**
  - Currently canceling a Job build.
- **Disabled**
  - Not available to execute builds (see Disabling or deleting an agent).
- **Disabled - Building**
  - Currently executing a build, but disabled so cannot execute further builds.
- **Disabled - Canceling**
  - Currently canceling a build, and disabled so cannot execute further builds.

Note that to see the jobs that are currently being built, look at the **Current Activity** tab on the **dashboard**.

### Configuring capabilities

A **capability** is a feature of an **agent**. A capability can be defined on an agent for:

- an executable (e.g. Maven)
- a JDK
- a Version Control System client application (e.g. Git)
- a custom capability. This is a key-value property which defines a particular characteristic of an agent (e.g. `operating.system=WindowsXP` or `fast.builds=true`).

Capabilities typically define the path to an executable that has already been installed, and must be defined in Bamboo before Bamboo or its agents can make use of those.

Capabilities can be defined specifically for an agent, or they can be shared between either all local agents or all remote agents. Note that the value of an agent-specific capability overrides the value of a shared capability of the same name (if one exists).

See also [Configuring agents](#).
Defining a new capability

To define a new capability, see:

- Defining a new executable capability
- Defining a new JDK capability
- Defining a new custom capability
- Defining a new version control capability
- Defining a new Docker capability

Editing and deleting a capability

To edit an existing capability, see Modifying and deleting capabilities.

Renaming a capability

To rename an existing capability, see Renaming a capability.

Notes

- A requirement is specified in a job or a task. A requirement specifies a capability that an agent must have for it to build that job or task. A job inherits all of the requirements specified in its tasks.

  Together, capabilities and requirements control which agents can execute builds for particular jobs. Each job can only be built by agents whose capabilities match the job’s requirements.

  See Configuring a job’s requirements for more information.

About capabilities and requirements

A capability is a feature of an agent. A capability can be defined on an agent for:

- an executable (e.g. Maven)
- a JDK
- a Version Control System client application (e.g. Git)
- a custom capability. This is a key-value property which defines a particular characteristic of an agent (e.g. ‘operating.system=WindowsXP’ or ‘fast.builds=true’).

Capabilities typically define the path to an executable that has already been installed, and must be defined in Bamboo before Bamboo or its agents can make use of those.

Capabilities can be defined specifically for an agent, or they can be shared between either all local agents or all remote agents. Note that the value of an agent-specific capability overrides the value of a shared capability of the same name (if one exists).

See Configuring capabilities for more information.

Related pages:

- Configuring capabilities
- Configuring agents
- Remote agents
- Working with Elastic Bamboo

How do capabilities work with requirements?

A requirement is specified in a job or a task. A requirement specifies a capability that an agent must have for it to build that job or task. A job inherits all of the requirements specified in its tasks.

Together, capabilities and requirements control which agents can execute builds for particular jobs. Each job can only be built by agents whose capabilities match the job’s requirements.

See Configuring a job’s requirements for more information.

How are builds distributed to agents?
An agent will consume a single job at a time and will block any other Bamboo jobs from being processed until that job build is complete. If you would like to build multiple jobs simultaneously on the Bamboo server, then simply set up multiple local agents. If the agents are remote, then you will need to install that number of agent instances on the machine. Separate installations are required because each remote agent will need its own home and log directories.

How do capabilities affect the distribution of builds to agents?
Modifying and deleting capabilities

Depending on the capability type, you can edit parameters such as **Path**, **Java Home** and **Value** for the capability.

Note that:

- Because each agent can only run builds for jobs whose requirements are met by the agent’s capabilities (see Configuring a job’s requirements), modifying or deleting a capability may mean that some plans can no longer be built.
- Renaming a capability involves changing its key. See Renaming a capability.

On this page:
- Modifying an agent-specific capability
- Modifying a local server capability
- Modifying a shared remote capability

Related pages:
- Configuring capabilities

Modifying an agent-specific capability

To delete an agent-specific capability:

1. Navigate to the desired agent.
2. Click either **Edit** or **Delete** for the capability you wish to modify.

Modifying a local server capability

To delete a local server capability:

1. Click the **icon** in the Bamboo header and choose **Overview**.
2. Click **Server Capabilities** in the left navigation panel.
3. Click either **Edit** or **Delete** for the capability you wish to modify.

Modifying a shared remote capability

To delete a shared remote capability:

1. Click the **icon** in the Bamboo header and choose **Overview**.
2. Click **Agents** in the left navigation column.
3. Click **Shared Remote Capabilities** in the top right of the 'Remote Agents' section.
4. Click either **Edit** or **Delete** for the capability you wish to modify.

Renaming a capability

To rename a capability you have to change its key value.

Renaming an agent-specific capability

To rename a capability:

1. Click the **icon** in the Bamboo header and choose **Overview**.
2. Click **Agents** in the left panel (under 'Build Resources').
3. Click **View** for the agent that has the capability you wish to rename. A list of agent-specific capabilities and shared capabilities for that agent is displayed.
4. Click **View** for the capability you wish to rename.
5. Click **Rename Capability**. The 'Rename Capability' page will display.
6. Enter a value for **New key** and click **Rename Capability**.

<table>
<thead>
<tr>

</table>

Renaming a local server capability

To rename a local server capability:

1. Click the **icon** in the Bamboo header and choose **Overview**.
2. Click **Server Capabilities** in the left panel (under 'Build Resources').
3. Click **View** for the capability you wish to rename.
4. Click **Rename Capability**. The 'Rename Capability' page will display.
5. Enter a value for **New key** and click **Rename Capability**.

Renaming a shared remote capability

To rename a shared remote capability:

1. Click the **icon** in the Bamboo header and choose **Overview**.
2. Click **Agents** in the left panel (under ‘Build Resources’).
3. Click **Shared Remote Capabilities** in the ‘Remote Agents’ section.
4. Click **View** for the capability you wish to rename.
5. Click **Rename Capability**. The ‘Rename Capability’ page will display.
6. Enter a value for **New key** and click **Rename Capability**.

**Screenshot: Renaming a custom capability**

**Rename capability**

Update the label of this capability. Jobs with it as a requirement will be updated and all agents with this capability will be updated accordingly.

**Viewing a capability’s agents and jobs**

You can view a capability to see the following information about it:

- which **agents** have/inherit the capability. Click one of the listed agents to show further information about that agent:
  - **Executable Jobs** tab — all the jobs whose requirements match the capabilities of this agent
  - **Capabilities** tab — the capabilities of the agent itself
  - **System Properties** tab — system information about this agent
  - **Recent Activity** link — recent builds for the agent
- which **jobs** have the capability specified as a **requirement**.

- which **elastic images** have this capability and the Bamboo plans that rely on this capability. See also Viewing an elastic image.

**On this page:**
- Viewing an agent-specific capability
- Viewing a local server capability
- Viewing a shared remote capability

**Related pages:**
- Configuring capabilities
- Renaming a capability
- Modifying and deleting capabilities

**Viewing an agent-specific capability**

To view an agent-specific capability:

1. Navigate to the desired agent.
2. Click the **Capabilities** tab.
3. Click **View** for the capability you wish to view.

**Viewing a local server capability**

To view a local server capability:

1. Click the

   [icon in the Bamboo header and choose Overview.]
2. Click **Server Capabilities** in the left navigation panel.
3. Click **View** for the capability you wish to view.

**Viewing a shared remote capability**

Before you begin:

- Shared remote capabilities are **not shared** with elastic agents.

To view a shared remote capability:

1. Click the

   [icon in the Bamboo header and choose Overview.]
2. Click **Agents** in the left navigation column.
3. Click **Shared Remote Capabilities** in the top right of the ‘Remote Agents’ section.
4. Click **View** for the capability you wish to view.

**Defining a new executable capability**

An **executable** is an external program that Bamboo uses during the build process. Bamboo supports the following executables:

- Ant
- Maven
- Grails
- NAnt
- devenv.com
- msbuild.exe
- PHPUnit
- Custom command (e.g. 'make')
- Script

### On this page:

- Defining an agent-specific executable capability
- Defining a local server executable capability
- Defining a shared remote executable capability
- Notes

Executables must be defined as capabilities (that is, 'registered') in Bamboo before they can be used by tasks in a Bamboo job. At least one capability was automatically defined when you installed Bamboo, but you can define additional capabilities for other executables.

You can define an executable capability that is:

- for a specific local or remote agent
- shared by all local agents
- shared by all remote agents.

Once you have defined a new executable capability in your Bamboo system, its label (e.g. 'Ant') will appear in the **Executable** list when you use the executable in a task (see **Configuring tasks**). The executable you select will be used every time the task is run during a build. That is, the task can only be run by agents which have a capability that matches the executable specified in the task's **Executable** list.

Note that agent-specific capabilities override any shared capability of the same name.

**Defining an agent-specific executable capability**

An **agent-specific capability** applies to one agent only. Note that the value of an agent-specific capability will override the value of a **shared capability** of the same name (if one exists).

**To define a new agent-specific executable capability:**

1. Navigate to the desired agent.
2. In the 'Agent-Specific Capabilities' section of the **Capabilities** tab, click **Add Capability**. The 'Add Capability' page is displayed.
3. Choose **Capability Type > Executable**.
4. Select the appropriate executable from the **Type** list.
5. In the **Executable Label** field, type a name/label for the executable. Bamboo uses this name in the **Executables** list whenever a task's executable is configured.
6. In the **Path** field, type the path to the installed executable. This will depend on the **Type** you selected in the previous step.
7. Click **Add**. This will verify whether the executable and path you have specified are valid.

**Defining a local server executable capability**

Local server capabilities are inherited by all local agents. This means that local agents can all make use of the executables installed on the Bamboo server machine.

Before you begin:

- If you want to run multiple Maven agents on your local server, you will need to configure repository isolation for your Maven executables. See **Configuring repository isolation for Maven executables** for details.

**To define a new local server executable capability:**

1. Click the ![icon](image)
2. In the left navigation panel.
3. Choose **Capability Type > Executable** in the 'Add Capability' section at the end of the page.
4. Select the appropriate type of executable from the **Type** list.
5. In the **Executable Label** field, type a name/label for the executable, which Bamboo presents in the **Executables** list whenever a **Task** 's executable is configured.
6. In the **Path** field, type the appropriate path. This will depend on the **Type** you selected in the previous step.
Note that for Ant and Maven, Bamboo requires the path to be the location of the executable installation folder.

7. Click Add.

**Defining a shared remote executable capability**

Shared remote capabilities are inherited by all remote agents. However, Bamboo remote agents inherit only the paths of the shared executable capabilities, not the actual executable files. This means that every time you define a capability for an agent, you must make sure that the executable (for example, Ant or Maven) has actually been installed in that location on the remote server on which the remote agent will run.

Note that the value of a shared capability will be overridden by the value of an agent-specific capability of the same name (if one exists).

Shared remote executable capabilities are not shared with elastic agents.

**To define a shared remote executable capability:**

1. Click the icon in the Bamboo header and choose Overview.
2. Click Agents in the left navigation panel.
3. In the 'Remote Agents' section, click Shared Remote Capabilities at the right.
4. Choose Capability Type > Executable in the 'Add Capability' section.
5. Select the appropriate type of executable from the Type list.
6. In the Executable Label field, type a name/label to help you identify this executable.
7. In the Path field, type the appropriate path. This will depend on the Type you selected in the previous step.
8. Note that for Ant and Maven, Bamboo requires the path to be the location of the executable installation folder.
9. Click Add.

**Notes**

- **Pre-defined executables** — The executable that was automatically defined when you installed Bamboo depends on the system environment variables (e.g. 'ANT_HOME=/opt/java/ant') that were present on the machine that Bamboo was installed on.
  - On the Bamboo server, environment variables that were present during installation were saved as local server capabilities in Bamboo.
  - On remote agents, environment variables that were present during installation were saved as agent-specific capabilities in Bamboo.
- **Using other executables** — If you need to use an executable that is not natively supported by Bamboo, a number of third-party plugin modules are available (e.g. NoseXUnit). You can also create your own executable plugin (see the Bamboo Plugin Guide for details).
  - msbuild.exe — You will need to install the .NET framework SDK and reference the default path for msbuild.exe, (e.g. C:\Windows \Microsoft.NET\Framework*64\v2.0.50727), to use this executable.
  - PHPUnit — You will need to install PHPUnit and reference the path to your PHP command-line interpreter, (e.g. /usr/bin/phpunit on Ubuntu), to use this executable.

**Viewing your executable capabilities**

You can view all of the executable capabilities that have been defined in Bamboo on the 'Executables' page. These include local server capabilities, local agent-specific capabilities, and remote agent-specific capabilities.

An executable is an external program that Bamboo uses during the build process. Generally, executables compile source code to generate compiled executable files (referred to as artifacts in Bamboo). Ant, Maven, MSBuild or PHPUnit are just some examples of executables that can be used as part of your build process.

New executables can be defined as capabilities in Bamboo. Once an executable has been defined in Bamboo, it can be configured as part of a task.

On this page:
- Viewing and configuring executable capabilities
- Notes

Related pages:
- Configuring capabilities

**Viewing and configuring executable capabilities**

To view and configure the executable capabilities defined in Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Executables in the left navigation panel.
3. Click a specific executable's tab to see the agents and jobs related to this executable capability.
  - View more details about an agent with this executable capability — click the linked name of the agent in the 'Agent' column. This will show you the complete list of capabilities and jobs associated with that agent.
  - Edit the executable path of an agent with this capability — click Edit in the 'Operations' column for the agent you wish to configure. See Defining a new executable capability.
Remove this executable capability from an agent — click **Delete** in the 'Operations' column for the agent that currently possesses this executable capability.

⚠️ Be aware that you can only remove a executable capability from all local agents, not from individual local agents. See the note below for more information.

- **View details about (and configure) an elastic image with this executable capability** — click the linked name of the elastic image in the 'Elastic Image Configuration' column.
- **Configure a job that relies on or requires this executable capability** — click the linked name of the job in the 'Plan' column.
- If you are currently viewing a Maven (2.x or later) executable capability, you can configure repository isolation for it by clicking **Edit Capability Configuration**. Please refer to Configuring repository isolation for Maven executables for more information.
- **To add a new executable as a local server capability**, click **Add executable to server capabilities** to navigate to the 'Server Capabilities' page.

**Screenshot: Executables**

### Executable

The following table lists the executables that have been defined as capabilities in Bamboo. You can **add a executable as a server capability** on this page (shared by all local agents), or delete any of the existing executable capabilities listed. A executable can only be added as an agent-specific capability on that agent's page.

#### Ant

The screen shows the summary of a capability. You can see which jobs have a requirement on this capability and which agents have the capability.

**Rename Capability**

### Notes

- **Bamboo's automatic detection of executables** — When you install the Bamboo server application or the Bamboo Remote Agent application on another machine, either of these applications will automatically look for existing executables installed on the same machine (based on a combination of the machine’s environment variables and other conditions). A 'executable capability' will be created for each executable that either of these Bamboo applications find.

The environment variables and conditions that Bamboo uses to automatically detect and create executable capabilities are listed below. With the exception of the 'Command' executable, the paths for each automatically detected executable are based on the path 'string' values found within these environment variables.
1. **Ant** — the **ANT_HOME** environment variable
2. **Maven** — the **MAVEN_HOME** environment variable (Maven 1), **M2_HOME** or **MAVEN2_HOME** environment variable (Maven 2.x)
3. **Grails** — **GRAILS_HOME** environment variable
4. **Command** — the existence of the `/bin/bash` file
5. **PHPUnit** — the existence of the `phpunit` file anywhere within the machine’s PATH environment variable value

- **Local agents and executable capabilities** — Since Bamboo automatically looks for executables installed on the same machine and creates a 'executable capability' for each executable installation it finds, all existing and subsequent local agents that you create will possess these executable capabilities. Hence, when you access the 'Executables' page and view these executable capabilities, all local agents will be grouped together in the 'All local agents' category and you will only be able to remove these executable capabilities from **all** local agents, not from individual local agents.

### Configuring repository isolation for Maven executables

Bamboo allows you to isolate Maven (2.x or later only) executables on an agent-specific basis. If you configure repository isolation for a particular Maven executable capability, each agent that uses this executable will have its own private Maven 2.x artifacts directory, thereby allowing you to avoid these jar and dependency file corruptions. Each isolated repository directory has the path:

```
$BAMBOO_HOME/.m2/AGENT-${bamboo.agentId}/repository
```

**Related pages:**
- Defining a new executable capability

You may want to configure repository isolation for Maven executables, if you run multiple Maven executables on one server machine which **run under the same user account on that server**, but belong to **different Bamboo agents**. In this case, the agents will use the same default Maven artifacts directory: `~/.m2/repository` (or `%USERPROFILE%\m2\repository` for Windows-based servers). This is the directory to which Maven dependency jars are downloaded and where project artifacts are installed during the "install" phase of a Maven build.

Hence, problems can arise if Bamboo uses these multiple Maven executables simultaneously. For example, if multiple agents on a single computer, each with a different Maven executable capability, start to run Maven builds simultaneously from the queue, the different Maven executables may attempt to download the same dependency to the same artifacts directory location, resulting in corruption of the downloaded jar and dependency files.

**Before you begin:**
- This feature is not available for Maven 1.x executables.
- When configuring any Maven executables in Bamboo in which you want to force local repository isolation, ensure that the executable label you use is one that identifies it as such — for example, 'Maven 2.x with local repository isolation'.

### To configure a new local server Maven capability with repository isolation:

1. Click the **icon in the Bamboo header and choose Overview.**
2. Click **Server Capabilities** in the left navigation panel.
3. In the 'Add Capability' section, choose your executable and enter its details as described:

   **Capability Type**
   - **Select Executable**

   **Type**
   - Select one of the Maven options (2.x or later).

   **Executable Label**
   Enter 'Maven with local repository isolation'
   - You can use any label you wish. However, it will help you and your Bamboo users if you enter an appropriate executable label that identifies this Maven 2.x executable as one that uses local repository isolation.

   **Path**
   Enter the path for your Maven executable.

4. **Click Add.**
5. **Click the label for the executable you have just added.** The executable capability summary screen will be displayed (see 'Maven 2.x Executable' screenshot below).
6. **Click Edit Capability Configuration.** The 'Configure Capability' screen will be displayed (see 'Maven 2.x Repository Isolation' screenshot below).
7. **Select the Local repository isolation check box.**
8. **Click Save.**

.Configuring repository isolation for Maven executables v5.14

Bamboo allows you to isolate Maven (2.x or later only) executables on an agent-specific basis. If you configure repository isolation for a particular Maven executable capability, each agent that uses this executable will have its own private Maven 2.x artifacts directory, thereby allowing you to avoid these jar and dependency file corruptions. Each isolated repository directory has the path:

```
$BAMBOO_HOME/.m2/AGENT-${bamboo.agentId}/repository
```

You may want to configure repository isolation for Maven executables, if you run multiple Maven executables on one server machine which run under the same user account on that server, but belong to different Bamboo agents. In this case, the agents will use the same default Maven artifacts directory: `~/m2/repository` (or `%USERPROFILE%\m2\repository` for Windows-based servers). This is the directory to which Maven dependency jars are downloaded and where project artifacts are installed during the "install" phase of a Maven build.

Hence, problems can arise if Bamboo uses these multiple Maven executables simultaneously. For example, if multiple agents on a single computer, each with a different Maven executable capability, start to run Maven builds simultaneously from the queue, the different Maven executables may attempt to download the same dependency to the same artifacts directory location, resulting in corruption of the downloaded jar and dependency files.

Before you begin:

- This feature is not available for Maven 1.x executables.
- When configuring any Maven executables in Bamboo in which you want to force local repository isolation, ensure that the executable label you use is one that identifies it as such — for example, 'Maven 2.x with local repository isolation'.

To configure a new local server Maven capability with repository isolation:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Server Capabilities in the left navigation panel.
3. In the 'Add Capability' section, choose your executable and enter its details as described:

<table>
<thead>
<tr>

.Configuring repository isolation for Maven executables v6.1

Bamboo allows you to isolate Maven (2.x or later only) executables on an agent-specific basis. If you configure repository isolation for a particular Maven executable capability, each agent that uses this executable will have its own private Maven 2.x artifacts directory, thereby allowing you to avoid these jar and dependency file corruptions. Each isolated repository directory has the path:

$BAMBOO_HOME/.m2/AGENT-{$bamboo.agentId}/repository

You may want to configure repository isolation for Maven executables, if you run multiple Maven executables on one server machine which run under the same user account on that server, but belong to different Bamboo agents. In this case, the agents will use the same default Maven artifacts directory: $HOME/.m2/repository (or %USERPROFILE%\m2\repository for Windows-based servers). This is the directory to which Maven dependency jars are downloaded and where project artifacts are installed during the "install" phase of a Maven build.

Hence, problems can arise if Bamboo uses these multiple Maven executables simultaneously. For example, if multiple agents on a single computer, each with a different Maven executable capability, start to run Maven builds simultaneously from the queue, the different Maven executables may attempt to download the same dependency to the same artifacts directory location, resulting in corruption of the downloaded jar and dependency files.

Before you begin:

- This feature is not available for Maven 1.x executables.
- When configuring any Maven executables in Bamboo in which you want to force local repository isolation, ensure that the executable label you use is one that identifies it as such — for example, 'Maven 2.x with local repository isolation'.

To configure a new local server Maven capability with repository isolation:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Server Capabilities in the left navigation panel.
3. In the 'Add Capability' section, choose your executable and enter its details as described:
   - Capability Type: Select Executable
   - Type: Select one of the Maven options (2.x or later).
   - Executable Label: Enter 'Maven with local repository isolation'. You can use any label you wish. However, it will help you and your Bamboo users if you enter an appropriate executable label that identifies this Maven 2.x executable as one that uses local repository isolation.
   - Path: Enter the path for your Maven executable.
4. Click Add.
5. Click the label for the executable you have just added. The executable capability summary screen will be displayed (see 'Maven 2.x Executable' screenshot below).
6. Click Edit Capability Configuration. The 'Configure Capability' screen will be displayed (see 'Maven 2.x Repository Isolation' screenshot below).
7. Select the Local repository isolation check box.
8. Click Save.

Defining a new JDK capability

A JDK must be installed, and defined in Bamboo as a capability, before Bamboo can make use of it when building jobs.

At least one JDK was automatically defined when you installed Bamboo. You can define additional JDK capabilities that are:

- for a specific local or remote agent
- shared by all local agents
- shared by all remote agents.

**On this page:**
- Defining a JDK capability on an agent
- Defining a local server JDK capability
- Defining a shared remote JDK capability
- Notes

Once you have defined a new JDK capability in your Bamboo system, its label (e.g. ‘1.5’) will appear in the Build JDK list when you configure a job’s builder (see Configuring tasks). The JDK you select will be used for every one of that job’s builds. That is, the job can only be built by agents which have a JDK capability whose label is specified in the job's Build JDK field.

Note that if an agent has its own specific JDK capability, that value will override the value of a shared JDK capability of the same name (if one exists).

**Defining a JDK capability on an agent**

**To define a new agent-specific JDK capability:**

1. Click the ![icon](image)
   and select **Overview**.
2. Click **Agents** in the left panel.
3. Click the name of the required agent.
4. Click the **Capabilities** tab, and then **Add capability** (to the right of ‘Agent-Specific capabilities’).
5. Choose **Capability type > JDK**.
6. In the **JDK label** field, type a name/label for the JDK. Bamboo displays this in the Build JDK list whenever a job's builder is configured.
7. In the **Java home** field, type the location of the JDK Home Directory.
8. Click **Add**.

**Defining a local server JDK capability**

Local server capabilities are inherited by all local agents.

**To define a new local server JDK capability:**

1. Click the ![icon](image)
   in the Bamboo header and choose **Overview**.
2. Click **Server Capabilities** in the left navigation panel.
3. Choose **Capability Type > JDK** in the ‘Add Capability’ section at the end of the page.
4. In the **JDK Label** field, type a name/label for the JDK. Bamboo displays this in the Build JDK list whenever a job's builder is configured.
5. In the **Java Home** field, type the location of the JDK Home Directory.  
6. Click **Add**.

### Defining a shared remote JDK capability

Shared remote JDK capabilities are not shared with elastic agents.

To define a new shared remote JDK capability:

1. Click the ![gear icon](image) in the Bamboo header and choose **Overview**.  
2. Click **Agents** in the left navigation panel.  
3. In the 'Remote Agents' section, click **Shared Remote Capabilities** at the right.  
4. Choose **Capability Type** > **JDK** in the 'Add Capability' section at the end of the page (see screenshot below).  
5. In the **JDK Label** field, type a name/label for the JDK. Bamboo Bamboo displays this in the **Build JDK** list whenever a job's builder is configured.  
6. In the **Java Home** field, type the location of the JDK Home Directory.  
7. Click **Add**.

### Notes

- **Configuring generic JDK capabilities** — If you want to indicate that an agent is capable of running builds for a set of related JDKs (e.g. all point versions of JDK 1.5), you set up generic JDK capabilities to encompass these JDKs.  
  For example, you can set up the following JDK capabilities for your Bamboo agent(s):
  - **JDK** (where 'JDK Label' = 'JDK' and 'Java Home' = '/usr/java/jdk1.5.0_07') — this JDK capability indicates that an agent(s) is capable of running builds with any JDK requirement.  
  - **JDK 1.5** (where 'JDK Label' = 'JDK 1.5' and 'Java Home' = '/usr/java/jdk1.5.0_07') — this JDK capability indicates that an agent(s) is capable of running builds with a JDK 1.5 requirement or any point version of JDK 1.5, e.g. 1.5.0_07, 1.5.0_08, etc.  
  - **JDK 1.5.0_07** (where 'JDK Label' = 'JDK 1.5.0_07' and 'Java Home' = '/usr/java/jdk1.5.0_07') — this JDK capability indicates that an agent(s) is only capable of running builds with a JDK 1.5.0_07 requirement.
- If you wish to find redundant JDK capabilities, you can view the list of JDK capabilities set up in Bamboo and delete any unwanted JDK capabilities.

- **Automatically defined capabilities** — This depends on the system environment variables (e.g. `JAVA_HOME=/opt/java/java_sdk1.5`) that were present on the machine on which Bamboo was installed:
  - On the Bamboo server, environment variables that were present during installation were saved as shared local capabilities in Bamboo.  
  - On remote agents, environment variables that were present during installation were saved as agent-specific capabilities in Bamboo.

### Viewing your JDK capabilities

You can view all the JDK capabilities that have been defined in your Bamboo system on the **JDKs** page. These include local server capabilities, local agent-specific capabilities and remote agent-specific capabilities.

Note the following:

- **Bamboo's automatic detection of JDKs** — When you install either Bamboo or the Bamboo Remote Agent, it will automatically look for an existing JDK installed on the same machine (based on the machine's `JAVA_HOME` environment variable) and create a 'JDK capability' for that JDK installation, with its path being the value of `JAVA_HOME`.  
- **Local agents and JDK capabilities** — Since Bamboo automatically looks for an existing JDK installed on the same machine and creates a 'JDK capability' for it, all existing and subsequent local agents that you create will possess this JDK capability. Hence, when you access the 'JDKs' page and view this JDK capability, all local agents will be grouped together in the 'All local agents' category and you will only be able to remove this JDK capability from all local agents, not from individual local agents.

### Related pages:

- Defining a new JDK capability

### To view and configure the JDK capabilities defined in Bamboo:

1. Click the ![gear icon](image) in the Bamboo header and choose **Overview**.  
2. Click **JDKs** (under 'Build Resources') in the left navigation panel.  
3. Click the tab for a specific JDK to see the agents and jobs related to this JDK capability.
   - View the capabilities and jobs associated with an agent with this JDK capability — click the linked name of the agent in the 'Agent' column. See Viewing a capability's agents and jobs.
   - Edit **JAVA_HOME** for an agent — click **Edit** in the 'Operations' column for the agent you wish to configure. See Defining a new JDK capability.
Remove this JDK capability from an agent — click **Delete** in the 'Operations' column for the agent that currently possesses this JDK capability.

⚠️ Be aware that you can only remove a JDK capability from all local agents, not from individual local agents. See the note above for more information.

View details about (and configure) an elastic image with this JDK capability — click the name of the elastic image in the 'Elastic Image Configuration' column. See Viewing an elastic image.

Configure a job that relies on this JDK capability — click the name of the job in the 'Plan' column.

To add a new JDK as a local server capability, click **add a JDK as a server capability** at the top of the page. This opens the 'Server Capabilities' page at the 'Add Capability' section, with the JDK selected as the Capability Type.

</table>

**Rename Capability**
Defining a new version control capability

Version control capabilities let Bamboo know where the client application for a version control system is located, so that Bamboo can perform a checkout while building. Bamboo requires that a capability for at least one of the following version control repositories be set so that Bamboo can check out source code from that repository type:

- Bitbucket Cloud
- Git
  - If no capability is provided, Bamboo will use its built-in Git implementation. Note that the built-in Git implementation does not support symbolic links, submodules, automatic branch detection or automatic merging.
- Mercurial
- Perforce

Note that there is no need to create a SVN capability as SVN support is built into every Bamboo agent.

Example version control executable paths

For the version control systems that require capabilities to be set on agents, the following table offers example paths for both Linux and Windows systems.

Note that these paths may differ on your actual system's configuration.

<table>
<thead>
<tr>
<th>Capability type</th>
<th>Example paths</th>
</tr>
</thead>
<tbody>
<tr>
<td>Git</td>
<td>/usr/bin/git</td>
</tr>
<tr>
<td></td>
<td>C:\Program Files\Git\git.exe</td>
</tr>
<tr>
<td>Mercurial</td>
<td>/usr/local/bin/hg</td>
</tr>
<tr>
<td></td>
<td>C:\Program Files\Mercurial\hg.exe</td>
</tr>
</tbody>
</table>

To define a new version control capability

1. Navigate to the desired agent.
2. Select either a local or remote agent.
3. Choose the version control type you require from Capability Type.
4. Provide the full path to the client executable on the agent machine.

If you install a new agent on a machine that has Git already installed, the agent will find the Git client automatically.
To define a new version control capability

1. Navigate to the desired agent.
2. Select either a local or remote agent.
3. Choose the version control type you require from Capability Type.
4. Provide the full path to client executable on the agent machine.

If you install a new agent on a machine that has Git already installed, the agent will find the Git client automatically.

Version control capabilities let Bamboo know where the client application for a version control system is located, so that Bamboo can perform a checkout while building. Bamboo requires that a capability for at least one of the following version control repositories be set so that Bamboo can check out source code from that repository type:

- Bitbucket Cloud
- Git
  - If no capability is provided, Bamboo will use its built-in Git implementation. Note that the built-in Git implementation does not support symbolic links, submodules, automatic branch detection or automatic merging.
- Mercurial
- Perforce

Note that there is no need to create a SVN capability as SVN support is built into every Bamboo agent.

Example version control executable paths

- Perforce
Note that there is no need to create a SVN capability as SVN support is built into every Bamboo agent.

**Example version control executable paths**

For the version control systems that require capabilities to be set on agents, the following table offers example paths for both Linux and Windows systems.

Note that these paths may differ on your actual system’s configuration.

<table>
<thead>
<tr>
<th>Capability type</th>
<th>Example paths</th>
</tr>
</thead>
</table>
| Git             | - /usr/bin/git  
|                 | - C:\Program Files\Git\git.exe  
| Mercurial       | - /usr/local/bin/hg  
|                 | - C:\Program Files\Mercurial\hg.exe |

To define a new version control capability

1. Navigate to the desired agent.
2. Select either a local or remote agent.
3. Choose the version control type you require from **Capability Type**.
4. Provide the full path to client executable on the agent machine.

If you install a new agent on a machine that has Git already installed, the agent will find the Git client automatically.

**Defining a new version control capability v6.1**

Version control capabilities let Bamboo know where the client application for a version control system is located, so that Bamboo can perform a checkout while building. Bamboo requires that a capability for at least one of the following version control repositories be set so that Bamboo can check out source code from that repository type:

- Bitbucket Cloud
- Git
  - If no capability is provided, Bamboo will use its built-in Git implementation. Note that the built-in Git implementation does not support symbolic links, submodules, automatic branch detection or automatic merging.
- Mercurial
- Perforce

Note that there is no need to create a SVN capability as SVN support is built into every Bamboo agent.

**Example version control executable paths**

For the version control systems that require capabilities to be set on agents, the following table offers example paths for both Linux and Windows systems.

Note that these paths may differ on your actual system’s configuration.

<table>
<thead>
<tr>
<th>Capability type</th>
<th>Example paths</th>
</tr>
</thead>
</table>
| Git             | - /usr/bin/git  
|                 | - C:\Program Files\Git\git.exe  
| Mercurial       | - /usr/local/bin/hg  
|                 | - C:\Program Files\Mercurial\hg.exe |

To define a new version control capability

1. Navigate to the desired agent.
2. Select either a local or remote agent.
3. Choose the version control type you require from **Capability Type**.
4. Provide the full path to client executable on the agent machine.

If you install a new agent on a machine that has Git already installed, the agent will find the Git client automatically.

**Defining a new custom capability**

Custom capabilities can be used to control which jobs will be built by a particular agent, since agent capabilities are required to match job requirements. For example, if the builds for a particular job should only run in a Windows environment, you could create a custom capability `cpe rating.system=WindowsXP` for the appropriate agent(s), and specify it as a requirement for this job. (See Configuring a job’s requirements.)

You can define a custom capability that is:
Defining an agent-specific custom capability

To define a new agent-specific custom capability:

1. Navigate to the desired agent.
2. Click Add capability in the top right of the ‘Agent-Specific Capabilities’ section.
3. Choose Capability type > Custom.
4. Specify values for Key and Value.
5. Click Add.

Defining a local server custom capability

Local server capabilities are inherited by all local agents.

To define a new local server custom capability:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Server Capabilities in the left navigation panel (under ‘Build Resources’).
3. Locate the ‘Add Capability’ section at the bottom of the screen (see screenshot below).
4. Choose Capability Type > Custom.
5. Specify values for Key and Value.
6. Click Add.

Defining a shared remote custom capability

Shared remote custom capabilities are not shared with elastic agents.

To define a new shared remote custom capability:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Agents in the left navigation panel (under ‘Build Resources’).
3. Locate the ‘Remote Agents’ section.
4. Click Shared Remote Capabilities.
5. Locate the ‘Add Capability’ section at the bottom of the screen (see screenshot below).
6. Choose Capability Type > Custom.
7. Specify values for Key and Value.
Defining a new Docker capability

You need to define (that is, 'register') a Docker capability in Bamboo before you can use a Docker task in Bamboo builds and deployments.

If you’re using a Windows Bamboo server, you can’t run Docker commands directly from the Windows command line. To use the Docker task with a Windows Bamboo server, run Docker Machine.

A capability typically defines the path to a module or executable that has already been installed, and must be defined in Bamboo before Bamboo or its agents can make use of that.

For Bamboo 5.8, and later versions, Stock images already provide Docker, but you might still need to add the capability manually if you have upgraded from Bamboo 5.7 or an earlier version. See Existing stock images require manual update if new capabilities are needed for more details.

Note that Bamboo requires Docker 1.7.1 or later.

Define a Docker capability on an elastic image

1. Click the icon in the Bamboo header and choose Overview.
2. Click Image configurations in the left navigation panel (under 'Elastic Bamboo').
3. Click Capabilities (under 'Operations') for the relevant elastic image.
4. Use the 'Add Capability’ panel at the end of the page to add the new Docker capability to the image:
   - From Capability type, choose Docker.
   - For Path, enter the path to the Docker executable, for example /usr/bin/docker.
5. Click Add.

Define a Docker capability on an agent

1. Click the icon in the Bamboo header and choose Overview.
2. Click Agents in the left panel.
3. Click the name of the required agent.
4. Click the Capabilities tab, and then Add capability (to the right of 'Agent-Specific capabilities').
5. In the 'Add Capability' panel:
   - From Capability type, choose Docker.
   - For Path, enter the path to the Docker executable, for example /usr/bin/docker.
6. Click Add.

Define a Docker capability on the Bamboo server

1. Click the icon in the Bamboo header and choose Overview.
2. Click Server capabilities in the left navigation panel.
3. Use the 'Add Capability’ panel at the end of the page to add the new Docker capability to the server:
   - From Capability type, choose Docker.
   - For Path, enter the path to the Docker executable, for example /usr/bin/docker.
4. Click Add.

Remote agents

For information about installing and using remote agents, see the following pages:

- Bamboo remote agent installation guide
- Configuring remote agent capabilities using bamboo-capabilities.properties
- Disabling and enabling remote agents support

Disabling and enabling remote agents support
Remote agent support

Disabling remote agent support in Bamboo will disable all remote agents and prevent any users from creating new remote agents. This function will not delete any remote agents that you have already created. To delete a remote agent, see Disabling or deleting an agent.

Note that remote agent support must be enabled to use Elastic Bamboo. Disabling remote agent support will disable Elastic Bamboo.

To enable, or disable, remote agent support:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Agents (under ‘Build Resources’)
3. Click either Enable Remote Agent Support or Disable Remote Agent Support.

Remote agents

Remote agents run on computers other than the Bamboo server.

There are currently 4 remote agents online (1 non-elastic and 3 elastic). Start elastic agents here. A maximum of 100 agents are supported by your license.

Related pages:

- Agents and capabilities
- Configuring a job’s requirements

Additional remote agent options

This page describes additional options for running a Bamboo remote agent.

Changing where the remote agent stores its data

By default, the remote agent will store its data in a USER_HOME/bamboo-agent-home. If you wish to specify a different directory, add the following command line parameter before the JAR file name:

```
-Dbamboo.home=RemoteAgentHome
```

where RemoteAgentHome is the path to the Bamboo agent home directory you created in step 1.1.

Your command line will look something like this:

```
```

The name of the jar file (e.g. atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar) will vary depending on the version of Bamboo you are running.

Disabling auto-capability detection for the remote agent

There may be situations where you want to prevent Bamboo from automatically detecting and adding capabilities (such as JDKs) to the remote agent, or where you don’t want to run the remote agent with default capabilities.

```
Elastic agents don't support the DISABLE_AGENT_AUTO_CAPABILITY_DETECTION system property.
```

The DISABLE_AGENT_AUTO_CAPABILITY_DETECTION system property is handled only from the wrapper.conf file, not from the command line.

To update the property for a remote agent, add the following line to the <bamboo-agent-home>\conf\wrapper.conf file:
**wrapper.java.additional.3=-DDISABLE_AGENT_AUTO_CAPABILITY_DETECTION=true**

Then restart the agent with regular command `java -jar agent.jar URL_TO_SERVER SECURITY_TOKEN`

**Specifying a custom log4j file for the remote agent**

You can specify a custom log4j file in the wrapper.conf file. The file is located in `<bamboo-agent-home>/conf/wrapper.conf`.

Find the `wrapper.java.additional.3=-Dlog4j.configuration=` line, uncomment it and provide path to log4j.properties file at your disk. Then restart the agent with regular command `java -jar agent.jar URL_TO_SERVER SECURITY_TOKEN`.

**Changing the logging on the remote agent**

By default, the remote agent will use the same logging level as the Bamboo server. However, you can control the level of logging of your remote agent independently of your Bamboo server by setting up a separate logging configuration file.

Please see Logging in Bamboo for further details.

**Accepting self-signed certificates installed on the server**

Use the text-based keytool utility or GUI-based Portecle to add the self-signed certificate to the trusted certificates in your keystore.

**Disabling hostname verification for certificates**

If you are connecting to your Bamboo server via https (SSL is enabled) using a hostname or IP address that does not match the Common Name of your Bamboo server's certificate (or any of its Subject Alternative Names) you need to disable hostname verification:

Add the following parameter to the remote agent's command line:

```
-Dbamboo.agent.ignoreServerCertName=true
```

Your command line will look something like this:

```
```

⚠️ Please note that this reduces the security of your configuration, as the identity of your Bamboo server will not be authenticated by the remote agent.

**Running Bamboo without the Remote Agent Supervisor**

The remote agent supervisor is included in the remote agent JAR bundled with Bamboo. The appropriate remote agent supervisor for the operating system of your remote machine, will be automatically installed when you run the default remote agent start-up command line.

The remote agent supervisor cannot be installed on a small number of operating systems (i.e. the remote agent will start without the remote agent supervisor). If the remote agent supervisor fails to install, please check the operated systems list on the remote agent supervisor page. If your operating system is on the list and the remote agent supervisor still fails to install, please raise a support request in the Bamboo project.

If you need to run the remote agent without running the remote agent supervisor, you can execute the 'classic' version of the remote agent JAR. The 'classic' agent jar is available from Bamboo's agent installation page for download. Follow the steps below to run the 'classic' version of the remote agent:

1. Browse to:

```
http://<host>:8085/admin/agent/addRemoteAgent.action
```

2. Click the the direct agent JAR is available at bamboo-agent-2.2.2.jar link and save 'classic' agent jar.
3. Start the agent with:
Running the remote agent with different start-up commands

The remote agent supervisor is executed by default when you run the default remote agent start-up command line. The remote agent supervisor is implemented via a Java Service wrapper. The wrapper allows you to execute a number of general start-up commands when the remote agent is run. These commands are appended to the end of the default remote agent start-up command line:

```
java -jar atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer <wrapper_command>
```

where `<wrapper_command>` is one of the keywords described below:

- **console** — runs the remote agent in the foreground, i.e. display all of the commands on the screen. The agent home directory will be populated only if it is empty. This parameter is used by default.
- **start** — runs the remote agent in the background, i.e. no commands are displayed on screen. If you have installed the remote agent as a Windows service, this command will work with the service.
- **stop** — stops a remote agent that is running. If you have installed the remote agent as a Windows service, this command will work with the service.
- **status** — (non-Windows OS only) returns the status of the remote agent, e.g. "Remote agent is not running."
- **install** — installs the files for the remote agent, but does not start it. This will overwrite any changes that have been made to the wrapper.conf file. The agent home directory will be populated, regardless of whether it is empty or not, i.e. existing files will be overwritten. You may wish to use this option, if you want to customize the remote agent files before starting it.

Installing the remote agent as a Windows service (Windows only)

The remote agent supervisor is executed by default when you run the default remote agent start-up command line. The remote agent supervisor is implemented via a Java Service wrapper. The wrapper allows you to install or uninstall the remote agent as a service in Windows (i.e. start the Bamboo remote agent automatically when the machine boots). This is done by appending the appropriate wrapper commands to the end of the default remote agent start-up command line:

```
java -jar atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer <wrapper_command>
```

where `<wrapper_command>` is one of the keywords described below:

- **installntservice** — (Windows only) installs the remote agent as a Windows service.
- **uninstallntservice** — (Windows only) uninstalls the remote agent as a Windows service.

If you have installed the NT service, you will be able to use the start and stop start-up console commands with the service.

```
The name of the jar file (e.g. atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar) will vary depending on the version of Bamboo you are running.
```

1. The remote agents connect to the Bamboo server on the normal http/https port and 54663. You need to ensure that the network firewall isn't blocking these ports. If you're having issues connecting the remote agent with the Bamboo server, please this Troubleshooting Guide.

2. On Windows, when the Bamboo remote agent is installed as a service under the Local System user account. The temporary folder created by the agent isn't accessible by any other application. To allow enable to that folder, configure the agent to use a commonly accessible temporary folder by defining a new Java property in the service wrapper:

   1. Go to: `<BAMBOO_AGENT_HOME>/conf/wrapper.conf`
   2. Add the following line using the next property number as X:
      ```
      wrapper.java.additional.X=-Djava.io.tmpdir=C:\path\to\temp
      ```
   3. Restart the agent.

This page describes additional options for running a Bamboo remote agent.

On this page:

* Changing where the remote agent stores its data
* Disabling auto-capability detection for the remote agent
* Specifying a custom log4j file for the remote agent
* Accepting self-signed certificates installed on the server
* Disabling hostname verification for certificates
* Running Bamboo without the Remote Agent Supervisor
* Running the remote agent with different start-up commands
* Installing the remote agent as a Windows service (Windows only)

### Changing where the remote agent stores its data

By default, the remote agent will store its data in a USER_HOME/bamboo-agent-home. If you wish to specify a different directory, add the following command line parameter before the JAR file name:

```
-Dbamboo.home=RemoteAgentHome
```

where RemoteAgentHome is the path to the Bamboo agent home directory you created in step 1.1.

Your command line will look something like this:

```
java -Dbamboo.home=RemoteAgentHome -jar
atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer/
```

The name of the jar file (e.g. atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar) will vary depending on the version of Bamboo you are running.

### Disabling auto-capability detection for the remote agent

There may be situations where you want to prevent Bamboo from automatically detecting and adding capabilities (such as JDKs) to the remote agent, or where you don't want to run the remote agent with default capabilities.

The DISABLE_AGENT_AUTO_CAPABILITY_DETECTION system property is handled only from the wrapper.conf file, not from the command line.

To update the property for a remote agent, add the following line to the <bamboo-agent-home>/conf/wrapper.conf file:

```
wrapper.java.additional.3=-DDISABLE_AGENT_AUTO_CAPABILITY_DETECTION=true
```

Then restart the agent with regular command `java -jar agent.jar URL_TO_SERVER SECURITY_TOKEN`.

### Specifying a custom log4j file for the remote agent

You can specify a custom log4j file in the wrapper.conf file. The file is located in <bamboo-agent-home>/conf/wrapper.conf.

Find the `#wrapper.java.additional.3=-Dlog4j.configuration= line, uncomment it and provide path to log4j.properties file at your disk. Then restart the agent with regular command `java -jar agent.jar URL_TO_SERVER SECURITY_TOKEN`.

### Changing the logging on the remote agent

By default, the remote agent will use the same logging level as the Bamboo server. However, you can control the level of logging of your remote agent independently of your Bamboo server by setting up a separate logging configuration file.
Please see Logging in Bamboo for further details.

Accepting self-signed certificates installed on the server

Use the text-based keytool utility or GUI-based Portecle to add the self-signed certificate to the trusted certificates in your keystore.

Disabling hostname verification for certificates

If you are connecting to your Bamboo server via https (SSL is enabled) using a hostname or IP address that does not match the Common Name of your Bamboo server's certificate (or any of its Subject Alternative Names) you need to disable hostname verification:

Add the following parameter to the remote agent's command line:

```
-Dbamboo.agent.ignoreServerCertName=true
```

Your command line will look something like this:

```
java -Dbamboo.agent.ignoreServerCertName=true -jar
atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
https://bamboo-host-server:8085/agentServer/
```

⚠️ Please note that this reduces the security of your configuration, as the identity of your Bamboo server will not be authenticated by the remote agent.

Running Bamboo without the Remote Agent Supervisor

The remote agent supervisor is included in the remote agent JAR bundled with Bamboo. The appropriate remote agent supervisor for the operating system of your remote machine, will be automatically installed when you run the default remote agent start-up command line.

```
The remote agent supervisor cannot be installed on a small number of operating systems (i.e. the remote agent will start without the remote agent supervisor). If the remote agent supervisor fails to install, please check the operated systems list on the remote agent supervisor page. If your operating system is on the list and the remote agent supervisor still fails to install, please raise a support request in the Bamboo project.
```

If you need to run the remote agent without running the remote agent supervisor, you can execute the 'classic' version of the remote agent JAR.

The 'classic' agent JAR is available from Bamboo's agent installation page for download. Follow the steps below to run the 'classic' version of the remote agent:

1. Browse to:

   `http://<host>:8085/admin/agent/addRemoteAgent.action`

2. Click the direct agent JAR is available at bamboo-agent-2.2.2.jar link and save 'classic' agent JAR.

3. Start the agent with:

   `java -jar bamboo-agent-2.2.2.jar http://<host>:8085/agentServer/

⚠️ The name of the jar file (e.g. bamboo-agent-2.2.2.jar) will vary depending on the version of Bamboo you are running.

Running the remote agent with different start-up commands

The remote agent supervisor is executed by default when you run the default remote agent start-up command line. The remote agent supervisor is implemented via a Java Service wrapper. The wrapper allows you to execute a number of general start-up commands when the remote agent is run. These commands are appended to the end of the default remote agent start-up command line:
java -jar atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer <wrapper_command>

where <wrapper_command> is one of the keywords described below:

- **console** — runs the remote agent in the foreground, i.e. display all of the commands on the screen. The agent home directory will be populated only if it is empty. This parameter is used by default.
- **start** — runs the remote agent in the background, i.e. no commands are displayed on screen. If you have installed the remote agent as a Windows service, this command will work with the service.
- **stop** — stops a remote agent that is running. If you have installed the remote agent as a Windows service, this command will work with the service.
- **status** — (non-Windows OS only) returns the status of the remote agent, e.g. “Remote agent is not running.”
- **install** — installs the files for the remote agent, but does not start it. This will overwrite any changes that have been made to the wrapper.conf file. The agent home directory will be populated, regardless of whether it is empty or not, i.e. existing files will be overwritten. You may wish to use this option, if you want to customize the remote agent files before starting it.

The name of the jar file (e.g. atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar) will vary depending on the version of Bamboo you are running.

### Installing the remote agent as a Windows service (Windows only)

The remote agent supervisor is executed by default when you run the default remote agent start-up command line. The remote agent supervisor is implemented via a Java Service wrapper. The wrapper allows you to install or uninstall the remote agent as a service in Windows (i.e. start the Bamboo remote agent automatically when the machine boots). This is done by appending the appropriate wrapper commands to the end of the default remote agent start-up command line:

java -jar atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer <wrapper_command>

where <wrapper_command> is one of the keywords described below:

- **installntservice** — (Windows only) installs the remote agent as a Windows service.
- **uninstallntservice** — (Windows only) uninstalls the remote agent as a Windows service.

The name of the jar file (e.g. atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar) will vary depending on the version of Bamboo you are running.

If you have installed the NT service, you will be able to use the **start** and **stop** start-up console commands with the service.

The remote agents connect to the Bamboo server on the normal http/https port and 54663. You need to ensure that the network firewall isn’t blocking these ports. If you’re having issues connecting the remote agent with the Bamboo server, please see this Troubleshooting Guide.

### Additional remote agent options v5.15

This page describes additional options for running a Bamboo remote agent.

**Changing where the remote agent stores its data**

By default, the remote agent will store its data in a USER_HOME/bamboo-agent-home. If you wish to specify a different directory, add the following command line parameter before the JAR file name:

```
-Dbamboo.home=RemoteAgentHome
```

where RemoteAgentHome is the path to the Bamboo agent home directory you created in step 1.1. Your command line will look something like this:
java -Dbamboo.home=RemoteAgentHome -jar
atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer/

The name of the jar file (e.g. atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar) will vary depending on the version of Bamboo you are running.

Disabling auto-capability detection for the remote agent

There may be situations where you want to prevent Bamboo from automatically detecting and adding capabilities (such as JDKs) to the remote agent, or where you don't want to run the remote agent with default capabilities.

Elastic agents don't support the DISABLE_AGENT_AUTO_CAPABILITY_DETECTION system property.

The DISABLE_AGENT_AUTO_CAPABILITY_DETECTION system property is handled only from the wrapper.conf file, not from the command line.

To update the property for a remote agent, add the following line to the <bamboo-agent-home>/conf/wrapper.conf file:

```
wrapper.java.additional.3=-DDISABLE_AGENT_AUTO_CAPABILITY_DETECTION=true
```

Then restart the agent with regular command java -jar agent.jar URL_TO_SERVER SECURITY_TOKEN

Specifying a custom log4j file for the remote agent

You can specify a custom log4j file in the wrapper.conf file. The file is located in <bamboo-agent-home>/conf/wrapper.conf.

Find the line, uncomment it and provide path to log4j.properties file at your disk. Then restart the agent with regular command java -jar agent.jar URL_TO_SERVER SECURITY_TOKEN.

Changing the logging on the remote agent

By default, the remote agent will use the same logging level as the Bamboo server. However, you can control the level of logging of your remote agent independently of your Bamboo server by setting up a separate logging configuration file.

Please see Logging in Bamboo for further details.

Accepting self-signed certificates installed on the server

Use the text-based keytool utility or GUI-based Portecle to add the self-signed certificate to the trusted certificates in your keystore.

Disabling hostname verification for certificates

If you are connecting to your Bamboo server via https (SSL is enabled) using a hostname or IP address that does not match the Common Name of your Bamboo server's certificate (or any of its Subject Alternative Names) you need to disable hostname verification:

Add the following parameter to the remote agent's command line:

```
-Dbamboo.agent.ignoreServerCertName=true
```

Your command line will look something like this:

```
java -Dbamboo.agent.ignoreServerCertName=true -jar
atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
https://bamboo-host-server:8085/agentServer/
```

Please note that this reduces the security of your configuration, as the identity of your Bamboo server will not be authenticated by the remote agent.

Running Bamboo without the Remote Agent Supervisor

The remote agent supervisor is included in the remote agent JAR bundled with Bamboo. The appropriate remote agent supervisor for the operating system of your remote machine, will be automatically installed when you run the default remote agent start-up command line.
If you need to run the remote agent without running the remote agent supervisor, you can execute the 'classic' version of the remote agent JAR.

The 'classic' agent jar is available from Bamboo's agent installation page for download. Follow the steps below to run the 'classic' version of the remote agent:

1. Browse to:

   http://<host>:8085/admin/agent/addRemoteAgent.action

2. Click the [link](http://<host>:8085/admin/agent/addRemoteAgent.action) and save 'classic' agent jar.

3. Start the agent with:

   java -jar bamboo-agent-2.2.2.jar http://<host>:8085/agentServer/

You will need to replace `<host>` with the host name or IP address of your Bamboo instance.

**Running the remote agent with different start-up commands**

The remote agent supervisor is executed by default when you run the default remote agent start-up command line. The remote agent supervisor is implemented via a Java Service wrapper. The wrapper allows you to execute a number of general start-up commands when the remote agent is run. These commands are appended to the end of the default remote agent start-up command line:

```
java -jar atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer <wrapper_command>
```

where `<wrapper_command>` is one of the keywords described below:

- `console` — runs the remote agent in the foreground, i.e. display all of the commands on the screen. The agent home directory will be populated only if it is empty. This parameter is used by default.
- `start` — runs the remote agent in the background, i.e. no commands are displayed on screen. If you have installed the remote agent as a Windows service, this command will work with the service.
- `stop` — stops a remote agent that is running. If you have installed the remote agent as a Windows service, this command will work with the service.
- `status` — (non-Windows OS only) returns the status of the remote agent, e.g. “Remote agent is not running.”
- `install` — installs the files for the remote agent, but does not start it. This will overwrite any changes that have been made to the wrapper.conf file. The agent home directory will be populated, regardless of whether it is empty or not. i.e. existing files will be overwritten. You may wish to use this option, if you want to customize the remote agent files before starting it.

**Installing the remote agent as a Windows service (Windows only)**

The remote agent supervisor is executed by default when you run the default remote agent start-up command line. The remote agent supervisor is implemented via a Java Service wrapper. The wrapper allows you to install or uninstall the remote agent as a service in Windows (i.e. start the Bamboo remote agent automatically when the machine boots). This is done by appending the appropriate wrapper commands to the end of the default remote agent start-up command line:

```
java -jar atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer <wrapper_command>
```

where `<wrapper_command>` is one of the keywords described below:

- `installntservice` — (Windows only) installs the remote agent as a Windows service.
- `uninstallntservice` — (Windows only) uninstalls the remote agent as a Windows service.

**Unsupported operating systems**

The remote agent supervisor cannot be installed on a small number of operating systems (i.e. the remote agent will start without the remote agent supervisor). If the remote agent supervisor fails to install, please check the operated systems list on the remote agent supervisor page. If your operating system is on the list and the remote agent supervisor still fails to install, please raise a [support request](https://support.atlassian.com) in the Bamboo project.

---

Documentation for Bamboo 6.7

Created by Atlassian in 2018. Licensed under a [Creative Commons Attribution 2.5 Australia License](https://creativecommons.org/licenses/by/2.5/au/).
you are running.

If you have installed the NT service, you will be able to use the `start` and `stop` start-up console commands with the service.

- The remote agents connect to the Bamboo server on the normal http/https port and 54663. You need to ensure that the network firewall isn’t blocking these ports. If you’re having issues connecting the remote agent with the Bamboo server, please this Troubleshooting Guide

- On Windows, when the Bamboo remote agent is installed as a service under the Local System user account. The temporary folder created by the agent isn’t accessible by any other application. To allow enable to that folder, configure the agent to use a commonly accessible temporary folder by defining a new Java property in the service wrapper:
  1. Go to: `<BAMBOO_AGENT_HOME>/conf/wrapper.conf`
  2. Add the following line using the next property number as X:
     ```
     wrapper.java.additional.X=-Djava.io.tmpdir=C:\path\to\temp
     ```
  3. Restart the agent.

### Additional remote agent options v6.6

This page describes additional options for running a Bamboo remote agent. Additional options can be found in *How to extend the Remote agent installation command using JVM parameters.*

#### Changing where the remote agent stores its data

By default, the remote agent will store its data in a USER_HOME/bamboo-agent-home. If you wish to specify a different directory, add the following command line parameter before the JAR file name:

```
-Dbamboo.home=RemoteAgentHome
```

where `RemoteAgentHome` is the path to the Bamboo agent home directory you created in step 1.1.

Your command line will look something like this:

```
java -Dbamboo.home=RemoteAgentHome -jar
atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer/
```

The name of the jar file (e.g. `atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar`) will vary depending on the version of Bamboo you are running.

#### Disabling auto-capability detection for the remote agent

There may be situations where you want to prevent Bamboo from automatically detecting and adding capabilities (such as JDKs) to the remote agent, or where you don’t want to run the remote agent with default capabilities.

```
wrapper.java.additional.3=-DDISABLE_AGENT_AUTO_CAPABILITY_DETECTION=true
```

Elastic agents don’t support the `DISABLE_AGENT_AUTO_CAPABILITY_DETECTION` system property.

The `DISABLE_AGENT_AUTO_CAPABILITY_DETECTION` system property is handled only from the wrapper.conf file, not from the command line.

To update the property for a remote agent, add the following line to the `<bamboo-agent-home>/conf/wrapper.conf` file:

```
wrapper.java.additional.3=-DDISABLE_AGENT_AUTO_CAPABILITY_DETECTION=true
```

Then restart the agent with regular command `java -jar agent.jar URL_TO_SERVER SECURITY_TOKEN`

#### Specifying a custom log4j file for the remote agent

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
You can specify a custom log4j file in the wrapper.conf file. The file is located in `<bamboo-agent-home>/conf/wrapper.conf`. Find the `#wrapper.java.additional.3=-Dlog4j.configuration=` line, uncomment it and provide path to log4j.properties file at your disk. Then restart the agent with regular command `java -jar agent.jar URL_TO_SERVER SECURITY_TOKEN`.

Changing the logging on the remote agent

By default, the remote agent will use the same logging level as the Bamboo server. However, you can control the level of logging of your remote agent independently of your Bamboo server by setting up a separate logging configuration file.

Please see Logging in Bamboo for further details.

- **Accepting self-signed certificates installed on the server**
  Use the text-based keytool utility or GUI-based Portecle to add the self-signed certificate to the trusted certificates in your keystore.

- **Disabling hostname verification for certificates**
  If you are connecting to your Bamboo server via https (SSL is enabled) using a hostname or IP address that does not match the Common Name of your Bamboo server's certificate (or any of its Subject Alternative Names) you need to disable hostname verification:

    Add the following parameter to the remote agent's command line:

    ```
    -Dbamboo.agent.ignoreServerCertName=true
    ```

    Your command line will look something like this:

    ```
    java -Dbamboo.agent.ignoreServerCertName=true -jar
    atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
    https://bamboo-host-server:8085/agentServer/
    ```

    Please note that this reduces the security of your configuration, as the identity of your Bamboo server will not be authenticated by the remote agent.

- **Running Bamboo without the Remote Agent Supervisor**

  The remote agent supervisor is included in the remote agent JAR bundled with Bamboo. The appropriate remote agent supervisor for the operating system of your remote machine, will be automatically installed when you run the default remote agent start-up command line.

  The remote agent supervisor cannot be installed on a small number of operating systems (i.e. the remote agent will start without the remote agent supervisor). If the remote agent supervisor fails to install, please check the operated systems list on the remote agent supervisor page. If your operating system is on the list and the remote agent supervisor still fails to install, please raise a support request in the Bamboo project.

  If you need to run the remote agent without running the remote agent supervisor, you can execute the 'classic' version of the remote agent JAR. The 'classic' agent jar is available from Bamboo's agent installation page for download. Follow the steps below to run the 'classic' version of the remote agent:

  1. Browse to:

     ```
     http://<host>:8085/admin/agent/addRemoteAgent.action
     ```

  2. Click the the direct agent JAR is available at bamboo-agent-2.2.2.jar link and save 'classic' agent jar.

  3. Start the agent with:

     ```
     java -jar bamboo-agent-2.2.2.jar http://<host>:8085/agentServer/
     ```

     The name of the jar file (e.g. bamboo-agent-2.2.2.jar) will vary depending on the version of Bamboo you are running.

- **Running the remote agent with different start-up commands**

  The remote agent supervisor is executed by default when you run the default remote agent start-up command line. The remote agent supervisor is implemented via a Java Service wrapper. The wrapper allows you to execute a number of general start-up commands
when the remote agent is run. These commands are appended to the end of the default remote agent start-up command line:

```
java -jar atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer <wrapper_command>
```

where `<wrapper_command>` is one of the keywords described below:

- **console** — runs the remote agent in the foreground, i.e. display all of the commands on the screen. The agent home directory will be populated only if it is empty. This parameter is used by default.
- **start** — runs the remote agent in the background, i.e. no commands are displayed on screen. If you have installed the remote agent as a Windows service, this command will work with the service.
- **stop** — stops a remote agent that is running. If you have installed the remote agent as a Windows service, this command will work with the service.
- **status** — (non-Windows OS only) returns the status of the remote agent, e.g. "Remote agent is not running."
- **install** — installs the files for the remote agent, but does not start it. This will overwrite any changes that have been made to the wrapper.conf file. The agent home directory will be populated, regardless of whether it is empty or not, i.e. existing files will be overwritten. You may wish to use this option, if you want to customize the remote agent files before starting it.

The name of the jar file (e.g. atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar) will vary depending on the version of Bamboo you are running.

### Installing the remote agent as a Windows service (Windows only)

The remote agent supervisor is executed by default when you run the default remote agent start-up command line. The remote agent supervisor is implemented via a Java Service wrapper. The wrapper allows you to install or uninstall the remote agent as a service in Windows (i.e. start the Bamboo remote agent automatically when the machine boots). This is done by appending the appropriate wrapper commands to the end of the default remote agent start-up command line:

```
java -jar atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer <wrapper_command>
```

where `<wrapper_command>` is one of the keywords described below:

- **installnts** — *(Windows only)* installs the remote agent as a Windows service.
- **uninstallnts** — *(Windows only)* uninstalls the remote agent as a Windows service.

The name of the jar file (e.g. atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar) will vary depending on the version of Bamboo you are running.

If you have installed the NT service, you will be able to use the `start` and `stop` start-up console commands with the service.

- The remote agents connect to the Bamboo server on the normal http/https port and 54663. You need to ensure that the network firewall isn't blocking these ports. If you're having issues connecting the remote agent with the Bamboo server, please see this Troubleshooting Guide.
- On Windows, when the Bamboo remote agent is installed as a service under the Local System user account. The temporary folder created by the agent isn't accessible by any other application. To allow enable to that folder, configure the agent to use a commonly accessible temporary folder by defining a new Java property in the service wrapper:
  1. Go to: `<BAMBOO_AGENT_HOME>/conf/wrapper.conf`
  2. Add the following line using the next property number as X:
     ```java
     wrapper.java.additional.X=-Djava.io.tmpdir=C:\path\to\temp
     ```
  3. Restart the agent.

### Additional remote agent options v6.7

This page describes additional options for running a Bamboo remote agent. Additional options can be found in *How to extend the Remote agent installation command using JVM parameters*.
Changing where the remote agent stores its data

By default, the remote agent will store its data in a USER_HOME/bamboo-agent-home. If you wish to specify a different directory, add the following command line parameter before the JAR file name:

```
-Dbamboo.home=RemoteAgentHome
```

where RemoteAgentHome is the path to the Bamboo agent home directory you created in step 1.1.

Your command line will look something like this:

```
java -Dbamboo.home=RemoteAgentHome -jar
atlassian-bamboo-agent-installer-X.X-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer/
```

The name of the jar file (e.g. atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar) will vary depending on the version of Bamboo you are running.

Disabling auto-capability detection for the remote agent

There may be situations where you want to prevent Bamboo from automatically detecting and adding capabilities (such as JDKs) to the remote agent, or where you don't want to run the remote agent with default capabilities.

```
Elastic agents don't support the DISABLE_AGENT_AUTO_CAPABILITY_DETECTION system property.
```

The DISABLE_AGENT_AUTO_CAPABILITY_DETECTION system property is handled only from the wrapper.conf file, not from the command line.

To update the property for a remote agent, add the following line to the <bamboo-agent-home>/conf/wrapper.conf file:

```
wrapper.java.additional.3=-DDISABLE_AGENT_AUTO_CAPABILITY_DETECTION=true
```

Then restart the agent with regular command `java -jar agent.jar URL_TO_SERVER SECURITY_TOKEN`

Specifying a custom log4j file for the remote agent

You can specify a custom log4j file in the wrapper.conf file. The file is located in <bamboo-agent-home>/conf/wrapper.conf.

Find the `wrapper.java.additional.3=-Dlog4j.configuration=` line, uncomment it and provide path to log4j.properties file at your disk. Then restart the agent with regular command `java -jar agent.jar URL_TO_SERVER SECURITY_TOKEN`.

Changing the logging on the remote agent

By default, the remote agent will use the same logging level as the Bamboo server. However, you can control the level of logging of your remote agent independently of your Bamboo server by setting up a separate logging configuration file.

Please see Logging in Bamboo for further details.

Accepting self-signed certificates installed on the server

Use the text-based keytool utility or GUI-based Portecle to add the self-signed certificate to the trusted certificates in your keystore.

Disabling hostname verification for certificates

If you are connecting to your Bamboo server via https (SSL is enabled) using a hostname or IP address that does not match the Common Name of your Bamboo server's certificate (or any of its Subject Alternative Names) you need to disable hostname verification:

Add the following parameter to the remote agent's command line:

```
-Dbamboo.agent.ignoreServerCertName=true
```

Your command line will look something like this:
Please note that this reduces the security of your configuration, as the identity of your Bamboo server will not be authenticated by the remote agent.

**Running Bamboo without the Remote Agent Supervisor**

The remote agent supervisor is included in the remote agent JAR bundled with Bamboo. The appropriate remote agent supervisor for the operating system of your remote machine, will be automatically installed when you run the default remote agent start-up command line.

Running the remote agent with different start-up commands

The remote agent supervisor is executed by default when you run the default remote agent start-up command line. The remote agent supervisor is implemented via a Java Service wrapper. The wrapper allows you to execute a number of general start-up commands when the remote agent is run. These commands are appended to the end of the default remote agent start-up command line:

```
java -jar atlassian-bamboo-agent-installer-2.2-<SNAPSHOT>.jar http://<host>:8085/agentServer/"<wrapper_command>
```

where `<wrapper_command>` is one of the keywords described below:

- **console** — runs the remote agent in the foreground, i.e. display all of the commands on the screen. The agent home directory will be populated only if it is empty. This parameter is used by default.
- **start** — runs the remote agent in the background, i.e. no commands are displayed on screen. If you have installed the remote agent as a Windows service, this command will work with the service.
- **stop** — stops a remote agent that is running. If you have installed the remote agent as a Windows service, this command will work with the service.
- **status** — (non-Windows OS only) returns the status of the remote agent, e.g. “Remote agent is not running.”
- **install** — installs the files for the remote agent, but does not start it. This will overwrite any changes that have been made to the wrapper.conf file. The agent home directory will be populated, regardless of whether it is empty or not, i.e. existing files will be overwritten. You may wish to use this option, if you want to customize the remote agent files before starting it.

The name of the jar file (e.g. atlassian-bamboo-agent-installer-2.2-<SNAPSHOT>.jar) will vary depending on the version of Bamboo you are running.

**Installing the remote agent as a Windows service (Windows only)**
The remote agent supervisor is executed by default when you run the default remote agent start-up command line. The remote agent supervisor is implemented via a Java Service wrapper. The wrapper allows you to install or uninstall the remote agent as a service in Windows (i.e. start the Bamboo remote agent automatically when the machine boots). This is done by appending the appropriate wrapper commands to the end of the default remote agent start-up command line:

```
java -jar atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar
http://bamboo-host-server:8085/agentServer <wrapper_command>
```

where <wrapper_command> is one of the keywords described below:

- `installntservice` — (Windows only) installs the remote agent as a Windows service.
- `uninstallntservice` — (Windows only) uninstalls the remote agent as a Windows service.

The name of the jar file (e.g. `atlassian-bamboo-agent-installer-2.2-SNAPSHOT.jar`) will vary depending on the version of Bamboo you are running.

If you have installed the NT service, you will be able to use the `start` and `stop` start-up console commands with the service.

- The remote agents connect to the Bamboo server on the normal http/https port and 54663. You need to ensure that the network firewall isn't blocking these ports. If you're having issues connecting the remote agent with the Bamboo server, please this Troubleshooting Guide.
- On Windows, when the Bamboo remote agent is installed as a service under the Local System user account, the temporary folder created by the agent isn't accessible by any other application. To allow enable to that folder, configure the agent to use a commonly accessible temporary folder by defining a new Java property in the service wrapper:
  1. Go to: `<BAMBOO_AGENT_HOME>/conf/wrapper.conf`
  2. Add the following line using the next property number as X:
     ```
     wrapper.java.additional.X=-Djava.io.tmpdir=C:\path\to\temp
     ```
  3. Restart the agent.

---

**Working with Elastic Bamboo**

Elastic Bamboo allows you to use computing resources from the Amazon Elastic Compute Cloud (EC2) to run builds. Elastic Bamboo uses a remote agent AMI (Amazon Machine Image) to create instances of remote agents in the Amazon EC2.

The following pages and sub-pages describe how to work with Elastic Bamboo:

- **About Elastic Bamboo** — Elastic Bamboo concepts.
- **Getting started with Elastic Bamboo** — setting up Elastic Bamboo for the first time. It contains instructions on enabling Elastic Bamboo for your Bamboo installation and running your first build.
- **Configuring Elastic Bamboo** — changing settings for Elastic Bamboo. This includes instructions on how to use Amazon's Elastic Block Storage to persist build information for your builds on Elastic Bamboo.
- **Managing your elastic images**
- **Managing your elastic instances**
- **Managing your elastic agents**
- **Elastic Bamboo FAQ** — running your builds using Elastic Bamboo.
- **Elastic Bamboo Security** — setting up secure communication between Bamboo and the EC2.

---

**About Elastic Bamboo**

On this page:

- **Conceptual Overview**
- **Key Terms**
- **Setting Up Elastic Bamboo**

---

**Conceptual Overview**

Elastic Bamboo allows you to use computing resources from the Amazon Elastic Compute Cloud (EC2) to run builds. Elastic Bamboo uses a remote agent AMI (Amazon Machine Image) to create instances of remote agents in the Amazon EC2.

_Elastic Bamboo Conceptual Overview_
A Bamboo build job can be run on an elastic agent, provided that the capabilities of the elastic agent meet the requirements of the job. Bamboo will assign the relevant job to an available elastic agent from the build queue automatically. The elastic agent must already be running for a job to be assigned to it.

An elastic agent is started by creating a new instance of an elastic image. Creating this new elastic instance automatically runs an elastic agent process in the instance. The agent inherits the capabilities of the image it was created from. Only one agent process can be run in an instance, although multiple instances can be created from the same image.

Once a job has completed running on an elastic agent, its results are made available (like those of any other job executed on a non-elastic agent). The elastic agent and instance will continue to run until they are shut down. Shutting down an elastic instance will terminate the agent, not take it offline. However, Bamboo will store historical information about the terminated elastic agent, such as the job which it has run.

An Amazon Web Services (AWS) account is required to use Elastic Bamboo. Elastic Bamboo Costs are charged by Amazon, separate to Bamboo license costs, as Elastic Bamboo is powered by Amazon resources.

Did you know you can configure Bamboo to start and shut down elastic instances automatically, based on build queue demands? Please refer to Configuring Elastic Bamboo for more information.

Key Terms

**Elastic Image**

An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer’s boot hard drive and elastic instances would be the software that runs on this operation system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an AMI ID.

You can associate multiple elastic images with a Bamboo server. One default shared image is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

You can also create your own custom elastic images.

**Elastic Instance**

An elastic instance is a running instance of an elastic image. One elastic instance is created whenever an elastic image is started. Hence, starting one elastic image multiple times, results in the creation of multiple elastic instances. Each time an elastic instance is created, one elastic agent is created on that instance.

---

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Conceptually, an elastic instance can be thought of as a computer. The elastic agent's processes are run on this computer and the elastic image is the boot hard drive. Unlike computers, however, elastic instances are temporary and stateless. When an elastic instance is shut down:

- Any changes that an elastic instance makes to the boot hard drive (e.g. agent log file) will not persist
- Any customizations to the instance itself will also be lost.

The Amazon Elastic Block Store can provide persistent storage for your elastic instances.

**Elastic Agent**

An elastic agent is an agent that runs in the Amazon Elastic Compute Cloud (EC2). An elastic agent process runs in an elastic instance of an elastic image. An elastic agent inherits its capabilities from the elastic image that it was created from.

**Setting Up Elastic Bamboo**

If you would like to set up Elastic Bamboo for your Bamboo installation, please read [Getting started with Elastic Bamboo](#). This document guides you through the initial configuration of Elastic Bamboo and running your first Job build.

**Elastic Bamboo Costs**

This page provides high level guidelines to Elastic Bamboo costs. As usage patterns vary from user to user, these guidelines are only intended to provide a picture of how Elastic Bamboo operates, not to make definitive pricing statements.

The Bamboo pricing page on the Atlassian website details the costs for Elastic Bamboo. This page is intended to complement that information.

### Amazon EC2 Pricing Information

You can use Elastic Bamboo to run remote agents on elastic instances in the Amazon Elastic Compute Cloud (EC2). If you choose to do this, you will be charged by Amazon for your EC2 compute usage. These charges will be billed to the AWS account that you provide.

*Please note, if you do not have an AWS account, you must register for one on the AWS registration page before you can enable Elastic Bamboo.*

Full details on Amazon EC2 pricing is available on the [Amazon EC2 pricing page](#). Please also note the following important information, which is relevant to EC2 usage by Elastic Bamboo:

- **You are responsible for all EC2 usage costs incurred on your AWS account.**
- Elastic Bamboo creates "High-CPU Medium" Instances by default, however you can configure the EC2 instance type. Read [Managing your elastic image configurations](#) for instructions on how to change your default instance type. Please note the different costs for different instance types.
- You are responsible for creating and shutting down resources required to run agents in EC2.
- You can track your EC2 usage in near real-time on the [AWS Account page](#).
- Your Elastic Bamboo compute usage will not be distinguishable from your non-Bamboo EC2 compute usage in your AWS billing.

### General Notes about EC2 Usage and Costs

The following information is based on our usage of Elastic Bamboo at Atlassian. These points are intended to be guidelines to EC2 usage and costs only.

- The bulk of EC2 costs from using Elastic Bamboo is for the uptime of EC2 instances. We strongly recommend that you shut down your instances when not in use.
- The costs for storing and moving data in and out of the EC2 will vary. However these costs are minimal (e.g. storing image) compared to instance uptime costs. Using the Amazon Elastic Block Store (EBS) with Elastic Bamboo can significantly reduce the data transfer (and associated costs) in and out of the EC2. Read more about configuring elastic instances to use EBS.
- The costs for using the Amazon Elastic Block Store (EBS) is minimal, relative to instance uptime costs.

**Elastic Bamboo Security**

Elastic Bamboo is a feature in Bamboo that allows Bamboo to dynamically source computing resources from the Amazon Elastic Compute Cloud (EC2).

All traffic sent between the agents located in EC2 and the Bamboo server is tunnelled through an SSL-encrypted tunnel. The tunnel will be initiated from the Bamboo Server to the EC2 instance, which means that you don't need to allow any inbound connections to your server. You will need to permit outbound traffic from the server on the tunnel port, however - the default port number is 26224. On the EC2 instance, only the tunnel port needs to be open for inbound traffic.

SSL tunneling is not implemented for VCS (Version Control System) to EC2 traffic though. You will need to make your VCS available for access from EC2 to use Elastic Bamboo. Please see the section on [setting up your VCS for Elastic Bamboo](#), which contains guidelines on securing your VCS.

Please be warned that just as with a regular host accessible from the Internet, if one of your remote agent instances is compromised, your Bamboo installation may be exposed to number of security vulnerabilities. These include confidential data (e.g. source code, VCS...
credentials) being stolen, malicious code being injected into elastic agents, unauthorized access to build queues and false information being submitted to Bamboo servers. Given that all Bamboo-related traffic is sent through a single encrypted connection, the risk of that happening is not high and can be further mitigated by setting up a VPC (Amazon Virtual Private Cloud). In a VPC, your elastic instances typically have no public IPs which means they are inaccessible from the internet other than through a regular, industry-standard VPN connection.

The sections below explain the default access rules for remote agent instances and how to change these rules, if desired.

### Default EC2 Access Rules

When you first use Elastic Bamboo, i.e. start an elastic instance, an 'elasticbamboo' security group will be set up for you on your AWS account. This security group is essentially a set of IP addresses that are permitted access to the EC2. By default, the security group will contain two rules — one to allow connections for Elastic Bamboo itself, and another to allow connections via SSH.

The EC2 security groups can be accessed via the AWS management console (see “Security Groups” in the left-hand menu under “Configuration”).

---

Related pages:
- Configuring Elastic Bamboo

---

Diagram above: Elastic Bamboo security architecture

**Default EC2 Access Rules**

When you first use Elastic Bamboo, i.e. start an elastic instance, an 'elasticbamboo' security group will be set up for you on your AWS account. This security group is essentially a set of IP addresses that are permitted access to the EC2. By default, the security group will contain two rules — one to allow connections for Elastic Bamboo itself, and another to allow connections via SSH.

The EC2 security groups can be accessed via the AWS management console (see “Security Groups” in the left-hand menu under “Configuration”).
Changing the Default EC2 Access Rules

If you wish to permit additional connections to your EC2 instance, you can do this by adding entries to the 'Allowed Connections' section for the 'elasticbamboo' security group. See the previous section on 'Default EC2 Access Rules' for instructions on how to access your EC2 security groups.

Using VPCs with Elastic Bamboo

VPC functionality is available with Bamboo 4.3. Amazon Virtual Private Cloud (Amazon VPC) lets you provision a private, isolated section of the Amazon Web Services (AWS) Cloud where you can launch AWS resources in a virtual network. By default, the instances running in that network will have no public IPs and will not be accessible to the computers outside of your VPC. You can also create a Hardware Virtual Private Network (VPN) connection between your company datacenter and your VPC and leverage the AWS cloud as an extension of your company datacenter. You can read more about VPCs on the Amazon Web Services VPC page.

Using a VPC means that your agents (and other instances launched in the VPC) will not be available on the Internet. There are several basic scenarios that can be realised using a VPC:

- Secure access to your company datacenter - agents can securely access resources from your internal network through a VPN connection. In this way, you can safely use your Version Control System or other internal resources such as databases from your Elastic Agents - without making them publicly accessible.
• Hiding some EC2 instances from the Internet - agents can communicate with your other hosts on the VPC using the internal network. This lets you e.g. set up an agent with a Windows-based DBMS and another one that runs tests against that DBMS from a different platform. Computers from outside of the VPC will not be able to access the DBMS because it will have no external IP. You don't need to use VPN for that use case, it's enough to assign an Elastic IP to the agent.
• Full-cloud deployment - you can host your Bamboo server in an Amazon's VPC and hide all your agents in a VPC. This will also let you access your other resources located in a VPC. The Bamboo Server can be accessed using VPN or an Elastic IP.

Setting up your Version Control System (VCS) for Elastic Bamboo

We recommend that you take the following steps to ensure that your Version Control System is set up securely for Elastic Bamboo:

1. Make your Version Control System accessible to the public internet
   You only need to do this if you are not using a VPC for agent connectivity. See using Bamboo with VPCs for more information.
   As SSL tunnelling is not implemented for VCS to EC2 connections, you will need to make your VCS accessible to the public internet to use Elastic Bamboo. If your VCS is behind a firewall this will involve configuring an access point in your firewall. Please consult the documentation for your firewall software for details on how to do this.

2. Use VCS authentication and access control
   We highly recommend that you secure access to your VCS by enabling the authentication and access control features on your VCS. Please consult the documentation for your VCS for details.

3. Use encrypted connections to VCS
   We also highly recommend that you use encrypted connections for your VCS (e.g. SSL). Please consult the documentation for your VCS for details.

About Elastic Bamboo v6.1

On this page:
• Conceptual Overview
• Key Terms
• Setting Up Elastic Bamboo

Conceptual Overview

Elastic Bamboo allows you to use computing resources from the Amazon Elastic Compute Cloud (EC2) to run builds. Elastic Bamboo uses a remote agent AMI (Amazon Machine Image) to create instances of remote agents in the Amazon EC2.
A Bamboo build job can be run on an elastic agent, provided that the capabilities of the elastic agent meet the requirements of the job. Bamboo will assign the relevant job to an available elastic agent from the build queue automatically. The elastic agent must already be running for a job to be assigned to it.

An elastic agent is started by creating a new instance of an elastic image. Creating this new elastic instance automatically runs an elastic agent process in the instance. The agent inherits the capabilities of the image it was created from. Only one agent process can be run in an instance, although multiple instances can be created from the same image.

Once a job has completed running on an elastic agent, its results are made available (like those of any other job executed on a non-elastic agent). The elastic agent and instance will continue to run until they are shut down. Shutting down an elastic instance will terminate the agent, not take it offline. However, Bamboo will store historical information about the terminated elastic agent, such as the job which it has run.

An Amazon Web Services (AWS) account is required to use Elastic Bamboo. Elastic Bamboo Costs are charged by Amazon, separate to Bamboo license costs, as Elastic Bamboo is powered by Amazon resources.

Did you know you can configure Bamboo to start and shut down elastic instances automatically, based on build queue demands? Please refer to Configuring Elastic Bamboo for more information.

**Key Terms**

**Elastic Image**

An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer’s boot hard drive and elastic instances would be the software that runs on this operating system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an AMI ID.

You can associate multiple elastic images with a Bamboo server. One default shared image is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

You can also create your own custom elastic images.

**Elastic Instance**

An elastic instance is a running instance of an elastic image. One elastic instance is created whenever an elastic image is started. Hence, starting one elastic image multiple times, results in the creation of multiple elastic instances. Each time an elastic instance is created, one elastic agent is created on that instance.
Conceptually, an elastic instance can be thought of as a computer. The elastic agent's processes are run on this computer and the elastic image is the boot hard drive. Unlike computers, however, elastic instances are temporary and stateless. When an elastic instance is shut down:

- Any changes that an elastic instance makes to the boot hard drive (e.g. agent log file) will not persist
- Any customizations to the instance itself will also be lost.

The Amazon Elastic Block Store can provide persistent storage for your elastic instances.

**Elastic Agent**

An elastic agent is an agent that runs in the Amazon Elastic Compute Cloud (EC2). An elastic agent process runs in an elastic instance of an elastic image. An elastic agent inherits its capabilities from the elastic image that it was created from.

**Setting Up Elastic Bamboo**

If you would like to set up Elastic Bamboo for your Bamboo installation, please read Getting started with Elastic Bamboo. This document guides you through the initial configuration of Elastic Bamboo and running your first Job build.

### About Elastic Bamboo v5.14

**On this page:**
- Conceptual Overview
- Key Terms
- Setting Up Elastic Bamboo

**Conceptual Overview**

Elastic Bamboo allows you to use computing resources from the Amazon Elastic Compute Cloud (EC2) to run builds. Elastic Bamboo uses a remote agent AMI (Amazon Machine Image) to create instances of remote agents in the Amazon EC2.

Elastic Bamboo Conceptual Overview

A Bamboo build job can be run on an elastic agent, provided that the capabilities of the elastic agent meet the requirements of the job.
Bamboo will assign the relevant job to an available elastic agent from the build queue automatically. The elastic agent must already be running for a job to be assigned to it.

An elastic agent is started by creating a new instance of an elastic image. Creating this new elastic instance automatically runs an elastic agent process in the instance. The agent inherits the capabilities of the image it was created from. Only one agent process can be run in an instance, although multiple instances can be created from the same image.

Once a job has completed running on an elastic agent, its results are made available (like those of any other job executed on a non-elastic agent). The elastic agent and instance will continue to run until they are shut down. Shutting down an elastic instance will terminate the agent, not take it offline. However, Bamboo will store historical information about the terminated elastic agent, such as the job which it has run.

An Amazon Web Services (AWS) account is required to use Elastic Bamboo. Elastic Bamboo Costs are charged by Amazon, separate to Bamboo license costs, as Elastic Bamboo is powered by Amazon resources.

Did you know you can configure Bamboo to start and shut down elastic instances automatically, based on build queue demands? Please refer to Configuring Elastic Bamboo for more information.

**Setting Up Elastic Bamboo**

If you would like to set up Elastic Bamboo for your Bamboo installation, please read Getting started with Elastic Bamboo. This document guides you through the initial configuration of Elastic Bamboo and running your first Job build.

**Getting started with Elastic Bamboo**

Elastic Bamboo allows you to use computing resources from the Amazon Elastic Compute Cloud (EC2) to run builds. Elastic Bamboo uses a remote agent AMI (Amazon Machine Image) to create instances of remote agents in the Amazon EC2.

**On this page:**

1. Read important documents
2. Enable and configure Elastic Bamboo
3. Start an Elastic Instance
4. Run a plan build
5. Shut down your Elastic instance
   Further information
1. Read important documents

If you are using Elastic Bamboo for the first time, we highly recommend that you start by reading the following important documents:

- **About Elastic Bamboo** — This high-level overview explains the key concepts behind the Elastic Bamboo feature.
- **Elastic Bamboo Security** — *We strongly recommend* that you read this document to understand the security implications of enabling Elastic Bamboo. This includes important information on securing your version control system (VCS) for use with Elastic Bamboo.
- **Elastic Bamboo Costs** — Elastic Bamboo sources resources from the Amazon Elastic Compute Cloud (EC2) which are charged separately to your Bamboo license fee. We recommend that you read this document to understand how you will be charged for using Elastic Bamboo.

2. Enable and configure Elastic Bamboo

Once you have understood the concepts, security implications and costs of Elastic Bamboo, you can enable and configure Elastic Bamboo for your Bamboo installation. You will also need to make your version control system (VCS) available to Amazon for Elastic Bamboo to work correctly.

2.1. Enabling Elastic Bamboo

To enable Elastic Bamboo:

1. Enable remote agent support in Bamboo — if you have disabled remote agent support, you must enable it before you can enable Elastic Bamboo. The Disabling and enabling remote agents support documentation also contains instructions on how to enable remote agent support.
2. In Bamboo, click **Administration** in the top menu bar.
3. Click **Configuration** in the left navigation panel (under 'Elastic Bamboo'). The 'Elastic Bamboo Configuration' screen will display.
4. Click **Enable**.

2.2. Configuring Elastic Bamboo

Before you can use Elastic Bamboo, you must configure it as detailed in the 'Configuring Elastic Bamboo' document. This is a simple three-step process:

1. Provide your Amazon Web Services account details
2. Configure your Elastic Bamboo global settings
3. Configure your elastic instance settings

- **Read the Configuring Elastic Bamboo document.**

2.3. Providing access to your VCS

You need to make your version control system available to Amazon to run job builds using Elastic Bamboo. This has security implications, particularly if your VCS is behind a firewall.

- **Read the Elastic Bamboo Security document for further instructions**, if you have not read it already.

3. Start an Elastic Instance

Now that you have enabled and configured Elastic Bamboo for your Bamboo installation, you can try building a plan with Elastic Bamboo. You can manually start an elastic instance using the Bamboo administration console. Starting an elastic instance will automatically start an elastic agent process on it.

- **Read about starting an elastic instance**

4. Run a plan build

To run a plan build on your elastic agent, you must set up a plan with its Default Job (plus any other optional jobs) all of whose requirements can meet your elastic agent's capabilities. Elastic agents inherit the capabilities of the image they are started from. We recommend that you use the Bamboo default image to start with.

- **Read about the capabilities of the default image.**

For the purposes of this guide, you should set up your plan so that its jobs' requirements can only be met by the elastic agent's capabilities. This will ensure that the jobs' builds run on your elastic agent. If you cannot set up your jobs' requirements to meet your elastic agent's capabilities, you can customize your elastic agent's capabilities to add a unique custom capability, e.g. `elastic=true`.

- **Read about configuring the capabilities of elastic agents.**
Job builds on elastic agents are run just like job builds on any other agent. You will see the progress of your build on your dashboard and can view the build result when it has completed.

Tip: You can significantly reduce the costs and time taken to run a job build by configuring Elastic Bamboo to use Amazon's Elastic Block Store (EBS).

5. Shut down your Elastic instance

When your job builds successfully, shut down your elastic instance. As described in Elastic Bamboo Costs, the bulk of your Elastic Bamboo costs are from instance uptime. We strongly recommend that you shut down your elastic instances when not in use.

- Read about shutting down an elastic instance.

Please note, that when you shut down an elastic instance, the agent process it is running is terminated. This means that elastic agents are not present on the 'Agents' page in Bamboo unless they are online. If you wish to view information about a terminated elastic agent, you can find the agent in the elastic agent usage history.

- Read about viewing your elastic agent usage history.

Congratulations! You have successfully set up and run a job build with Elastic Bamboo.

Further information

You may be interested in reading the following related topics below to help you manage and improve Elastic Bamboo's handling of job builds:

- Managing your elastic images, Managing your elastic instances, Managing your elastic agents — information hubs for managing Elastic Bamboo images, instances and agents.
- Configuring elastic instances to use the EBS — information on configuring Elastic Bamboo to use the Amazon Elastic Block Store (EBS) to improve job build times.

Configuring Elastic Bamboo

Elastic Bamboo allows you to use computing resources from the Amazon Elastic Compute Cloud (EC2) to run builds. Elastic Bamboo uses a remote agent AMI (Amazon Machine Image) to create instances of remote agents in the Amazon EC2.

Builds run on these 'elastic agents' in a similar way to how they run on local and remote agents.

If you have disabled remote agent support, you must enable it before you can enable Elastic Bamboo. Refer to Disabling and enabling remote agents support for instructions on how to enable remote agent support.

To configure your Amazon Web Services (AWS) account details or settings for Elastic Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. In the left navigation panel, go to Elastic Bamboo > Configuration.
3. Click Edit configuration.
4. Configure settings as described in the sections below.
5. Click Save when finished.

On this page:
- AWS account settings
- Global settings
- EC2 spot instances
- AWS settings
- Automatic elastic instance management

Related pages:
- AWS account for Bamboo
- Configuring elastic instances to use the EBS
- Disabling Elastic Bamboo

AWS account settings

Before you use Elastic Bamboo for the first time in your Bamboo instance, you must enter your Amazon Web Services (AWS) account details into the Bamboo application. If you do not have an AWS account, you must register for one on the AWS registration page before you can enable Elastic Bamboo.
Before you begin:

- Please note, Elastic Bamboo dynamically creates and runs remote agents in the Amazon Elastic Compute Cloud (EC2). Hence, if you choose to use Elastic Bamboo, you will be charged by Amazon for your EC2 compute usage (separately to your Bamboo license fee). These charges will be billed to the AWS account that you provide. Please read Elastic Bamboo Costs for more details.
- Please note, if you change your AWS account details, Bamboo will stop all elastic agents that are currently running.

To set your AWS account details:

You can enter or update your AWS Access Key ID and AWS Secret Access Key as follows:

1. Go to your account: choose My account/console from your user menu at the top right.
2. Click Security credentials.
3. Enter, or update, your AWS Access Key ID.
4. Select the Change AWS Secret Access Key? checkbox, and enter or update your AWS Secret Access Key.
5. Click Save.

Note that your AWS Access Key ID and AWS Secret Access Key are used together to identify you when accessing Amazon EC2 services. If you are unsure what your AWS Account ID and AWS Secret Access Key are, please refer to the Amazon documentation on AWS access identifiers.

Global settings

Elastic Bamboo provides you with a number of global configuration options to help you optimize EC2 usage for your Bamboo job builds. These settings control how the Bamboo server operates and how it manages its elastic instances and agents.

Maximum Number of Elastic Instances

The number of elastic instances that can be running at any one time. You may wish to decrease this value if you are concerned about EC2 compute costs, and you have a large number of concurrent job builds that cannot be supported by your non-elastic agents.

Automatically terminate elastic instance when elastic agent process ends

Controls whether your elastic instances will automatically shut down after the elastic agent processes running on them terminate.

- Shutdown Delay —controls how long an elastic instance will wait before shutting down, after its elastic agent process terminates.

EC2 spot instances

Elastic Bamboo provides support for Amazon EC2 Spot Instances. Amazon spot instances allow you to bid on unused EC2 capacity and use it, as long as your bid exceeds the current "Spot price". You can configure Elastic Bamboo to bid for a spot instance of a particular type, and fall back to a regular instance after a set amount of time if no instances are available.

Enable support for spot instances

Select this checkbox to enable support for spot instances.

Fallback to a regular instance after

The time (in minutes) after which Elastic Bamboo will fall back to using a regular instance, if a spot instance has not become available.

Your current bid levels (per hour)

Fill out this table with your bids. The bids are categorized by EC2 instance type and operating system.

AWS settings

These settings allow you to specify your AWS configuration settings in Bamboo so that Bamboo can operate elastic instances through your AWS account. This section includes settings that are used to configure elastic instances to work with the Amazon Elastic Block Store (EBS).

Using EBS with your elastic instances can significantly reduce the amount of data transfer required to run a job build, compared with starting a clean elastic instance. To find out more about this feature and how to set it up in Elastic Bamboo, read Configuring elastic instances to use the EBS.

Upload AWS account identifiers to new elastic instances

Select to upload the AWS Account Private Key File and Account Certificate File to all new elastic instances started. This is mandatory if you wish to use EBS to store job build information in a snapshot. However, you can also check this option if you are not using EBS (e.g. if you wish upload the AWS account identifiers in order to use Amazon's AWS command line tools).

Key files location

Choose how private key and certificate will be provided.

Account Private Key File

You must specify the location of this file to use the Amazon EBS with Elastic Bamboo. This file is generated by Amazon.

Account Certificate File

You must specify the location of this file to use the Amazon EBS with Elastic Bamboo. This file is generated by Amazon.
Automatic elastic instance management

The Automatic Elastic Instance Management feature allows Bamboo to start and shut down elastic instances automatically (based on build queue demands), so that you do not have to perform these actions manually. This feature reduces Bamboo administration overhead and can help minimize your overall elastic instance usage costs.

If a job's requirements cannot be met by any available online agents, this feature will start any elastic instance whose elastic agent has the capabilities to execute the job, so that the job's build can be generated. Regardless of how an elastic instance was started, all elastic instances will be shut down based on the settings specified below.

Elastic Instance Management

Choose from the following elastic instance management presets. Each of these presets define values for the five criteria described in the 'Custom' user-defined options (below). (Bear in mind that both the 'Aggressive' and 'Passive' presets have trade-offs.)

- **Default** — Balances build queue clearance rates with elastic instance usage costs.
- **Aggressive** — Favors higher build queue clearance rates but with higher elastic instance usage costs.
- **Passive** — Favors lower instance usage costs but with lower build queue clearance rates.
- **Custom** — Choose your own settings, as described below.
- **Disabled** — Disables Bamboo's automatic elastic instance management feature.

**Idle Agent Shutdown Delay**

Specify the number of minutes that an elastic agent must be idle before Bamboo shuts down the elastic instance running that agent. Elastic instances running in the Amazon EC2 compute cloud are charged in hourly blocks from the time they are started. To maximize usage of elastic instances in a cost-effective manner, Bamboo only performs these checks just prior to the expiry of each hourly block.

Allowed non-Bamboo instances

The maximum number of elastic instances allowed on your AWS account that are not controlled by this Bamboo instance. When this limit is exceeded, Bamboo will not start any new instances.

Maximum Number of Instances to Start at Once

The maximum number of elastic instances that Bamboo can start in one go. Bamboo only starts this maximum number of elastic instances on a 'per minute' basis.

Number of Builds in Queue Threshold

The total number of builds in a queue. When this and all other thresholds have been reached, new elastic instances will be started.

Number of Elastic Builds in Queue Threshold

The number of builds in the queue that can be executed on elastic instances. When this and all other thresholds have been reached, new elastic instances will be started.

Average Queue Time Threshold

The average number of minutes that job builds have been waiting in a queue. When this and all other thresholds have been reached, new elastic instances will be started.

Generating your AWS Private Key File and Certificate File

There are several security mechanisms associated with Amazon Web Services (AWS) and EC2:

- The AWS Access Key ID and Secret Access Key that are used by the Bamboo server to authenticate with AWS.
- A login key pair that you can use to log in to EC2 instances that have been started by Bamboo. The key pair is automatically generated, either the first time you use Elastic Bamboo, or if you delete the key pair. The key pair is listed as 'elasticbamboo' in your AWS console. Bamboo does not use this key pair.
- The AWS private key file and certificate file that are generated by Amazon and used together to allow Elastic Bamboo to securely access some of the AWS services, such as EBS for elastic instances and the Amazon command line tools. These are described below.

On this page:

- AWS private key file and certificate file
- Generating the files
- Downloading the files
- Notes

Related pages:

- Configuring Elastic Bamboo

AWS private key file and certificate file

These settings were used for older Bamboo setup. Since then, we've introduced a simplified mechanisms for working with instances as described above.
The Amazon Web Services (AWS) private key file and certificate file are generated by Amazon and work together to allow Elastic Bamboo to securely access your AWS account. These are required to enable certain features, such as EBS for elastic instances and the Amazon command line tools.

- The certificate file contains the public key associated with your AWS account. This file is kept by Amazon, (not on your Bamboo server).
- The private key file contains the private key that is used to authenticate requests to AWS. This file must be stored on your Bamboo server, if you are using EBS for elastic instances or the Amazon command line tools.
- The public key and private key from these files together form an X.509 certificate.

**Generating the files**

The certificate file will be kept by Amazon (to inject into your elastic instances) and the private key file will be downloaded to your Bamboo server in your Bamboo Home directory. If you are setting up Elastic Bamboo on multiple Bamboo servers using the same AWS account, you can simply copy the private key file across from the original Bamboo server. You should not need to regenerate the private key file and certificate file unless your private key file is lost or corrupted.

If you do need to regenerate the private key file and certificate file, please follow the instructions in the Amazon X.509 Certificates documentation. The Amazon documentation also contains instructions on using your own certificate, if you wish.

**Downloading the files**

We recommend that you store the files in the Home directory of your Bamboo server.

**Notes**

- If you wish to use this security mechanism with multiple Bamboo installations using the same AWS account (e.g. you have configured your elastic instances on each installation to use EBS), you will need to copy the AWS private key file and certificate file to each Bamboo server.
- You can only download the AWS private key file at the time it is generated. If the private key file has already been generated for your AWS account, you will not be able to download it from AWS again (for security purposes). You will have to copy it from wherever it was previously downloaded to. Otherwise you will have to generate a new private key file and certificate file to go with it.
  - If you regenerate a new private key file and certificate file, any Bamboo servers using the old private key file and certificate file will no longer be able to access the Amazon EC2, as only one X.509 certificate can be associated with your AWS account.
- You can download the AWS certificate file as many times as you want. This file does not need to be regenerated.

**Configuring elastic instances to use the EBS**

The Amazon Elastic Block Store (EBS) provides ‘EBS volumes’ which can attach to EC2 instances. EBS volumes (and the ‘EBS snapshots’ created from these volumes) provide persistent storage for your elastic instances.

If you have relatively static resources required for building your Bamboo jobs (such as, source code checkouts and Maven repository artifacts), you can add these to an EBS volume. From this volume, you can create an EBS snapshot, which effectively records the ‘state’ of an EBS volume at a given point in time.

After setting up an EBS snapshot, you can then associate it with an elastic image configuration. When this elastic image is started:

- its elastic instance will be started, along with the EBS volume (derived from the EBS snapshot associated with the elastic image) and
- this EBS volume will be attached to this elastic instance

Any build resources (added to the EBS volume prior to creating its snapshot) will be available to this elastic instance.

**Why should I use the EBS with Elastic Bamboo?**

Because an elastic instance is stateless, so also is the elastic agent that runs on it. Hence, every time an elastic instance is restarted from the same image:

- Any resources that its elastic agent must retrieve externally (for example, Maven repository artifacts), must be downloaded in their entirety.
- Full checkouts must be performed by elastic agents when new Jobs are built.

Therefore, you can use the EBS to store these external resources in an EBS volume and snapshot so that they do not have to be downloaded or source code checked out each time you start up an elastic instance from an image. If your jobs rely heavily on downloading such resources and/or you are not performing clean builds each time, the EBS may significantly improve your build times.

Additionally, the EBS provides an easy mechanism for customizing elastic agents, rather than you having to create a custom elastic image from scratch (with your own elastic agent capabilities). For example, you could upload files and scripts to your EBS volume that would install resources such as PostgreSQL databases for your elastic agents, which will be available when the agent’s elastic instance is started.

Creating your first EBS snapshot

To create your first EBS snapshot:

1. Download Amazon Web Services (AWS) account identifiers to your Bamboo server — You will need to store the AWS private key file and certificate file on your Bamboo server to use Elastic Bamboo with EBS. If you haven't downloaded an AWS private key file or certificate file to your Bamboo server yet, please see Generating your AWS Private Key File and Certificate File for instructions.
2. Update your Bamboo configuration settings with the location of the AWS account identifier files you have downloaded. This will ensure that these files are uploaded to any new elastic instances started. See the Elastic Instance Settings section on the Configuring Elastic Bamboo for instructions (you will need to update the Upload AWS account identifiers to new elastic instances (mandatory if EBS Snapshot ID specified) checkbox and Account Private Key File and Account Certificate File fields described on this page).
4. Access your elastic instance via SSH (see Accessing an elastic instance for instructions).
5. Log in as and administrator, such as root in Linux and, in Linux, make sure to load the root user's environment as below:

   ```
   sudo su -
   ```

   In this case, the ‘-’ or the ‘-l’ or the ‘-login’ parameters is required, otherwise some of the scripts may fail.

6. Follow the steps below to create an EBS volume and attach it to the elastic instance (steps a & b), upload content to the EBS volume (step c & d), and generate the snapshot (step e & f):

   All the scripts mentioned below are available in /opt/bamboo-elastic-agent/bin on Bamboo stock images. You can also download them from here (choose the latest version).

   a. Run `createInitialVolume.sh <volume size>` — This script creates a EBS volume (where <volume size> is the size of the volume), attaches the volume and mounts it on the elastic instance. For example, `createInitialVolume.sh 100` will create a 100GB EBS volume and attach and mount it on the elastic instance.

   b. Run `rewarmEbsSnapshot.sh` — This script sets up the standard structure for Elastic Bamboo on the EBS volume. The directories and files for this standard volume structure are detailed in the Important EBS Directories and Files section below.

   c. (optional) Populate your EBS volume — Your EBS volume can now be populated with any files and scripts that you wish to make available to the elastic instances that use the EBS volume. For example, you may want to upload maven repository data, source code, scripts and files to install databases on your elastic agents, etc. You must upload your files to the /mnt/bamboo-<imagename> folder or its subfolders, if you want them to be included in the snapshot. We recommend that you read Populating your EBS volume for guidelines on how to populate your EBS volume effectively.

   The EBS volume is attached to the elastic instance, so accessing your elastic instance via SSH will give you full access to the EBS volume (see Important EBS Directories and Files below).

   d. Ensure all uploaded content has the owner `bamboo:bamboo` — You can set the owner of a file by executing the following command: `chown -R bamboo:bamboo <filename>`

   e. Execute the `killall java` command — This command kills all processes on the instance, such as agent processes, so that the volume can be unmounted to be snapshotted.

   f. Run `generateSnapshot.sh` — This script unmounts and detaches the volume, before creating a snapshot based on the volume. The volume must be unmounted before the snapshot can be created. The time taken to create the snapshot will vary depending on the amount of content that you have uploaded to the EBS volume. The Snapshot ID for the snapshot will be available in the logs for the elastic instance. See Accessing an Elastic Instance for instructions on how to access the logs for your elastic instance.

   The device can not unmount if any terminals are currently in the mounted volume.

7. Shut down your elastic instance. See Shutting down an elastic instance for instructions.

Configuring an elastic image to use an EBS snapshot

Once you have set up an EBS snapshot, the final step is to add the snapshot details to an elastic image configuration, so that any instances started from that image will have EBS volumes attached to them. You can associate different snapshots with different elastic image configurations.

To configure Elastic Bamboo to use an EBS snapshot:

1. Determine the Snapshot ID of the EBS snapshot you have just created. The Snapshot ID should be recorded in the logs of the elastic instance you created it on. You can also view your EBS snapshots in the AWS Console by clicking the Snapshots menu item.

2. Click the

   ![icon](image)

   icon in the Bamboo header and choose Overview.

3. In the menu on the left, go to Elastic Bamboo > Image Configurations.

4. Click Edit in the 'Operations' column for the elastic image configuration that you would like to add your EBS snapshot to. The 'Edit Elastic Image Configuration - <imagename>-' screen will display (see screenshot below).
5. Check **Automatically attach an Amazon Elastic Block Store (EBS) volume to new elastic instances.**
6. Enter the Snapshot ID of your EBS snapshot in the **EBS Snapshot ID** field.
7. Check **Use legacy EBS handling** to resolve EBS issues for images older than two years.
8. Click **Save**. A new EBS volume will be created from the specified snapshot and attached to any new elastic instances started from that image.

**Updating your EBS snapshot**

If you are currently using EBS with Elastic Bamboo and want to update your snapshot, follow the instructions below. These are similar to the instructions for creating a new EBS snapshot.

**To update your EBS snapshot:**

1. Start a single elastic instance via Bamboo. See **Starting an elastic instance** for instructions.
2. (optional) Run a build on the elastic agent of the instance to populate the attached EBS volume. We recommend that you read **Populating your EBS volume** for guidelines on how to populate your EBS volume effectively.
3. Access your elastic instance via SSH (see **Accessing an elastic instance** for instructions) and do the following:
   
   a. Log in as and administrator, such as `root` in Linux and, in Linux, make sure to load the root user's environment as below:

   ```bash
   sudo su -
   ```

   In this case, the '-' or the '-l' or the '-login' parameters is required, otherwise some of the scripts may fail.

   b. (optional) Upload any additional content to the attached EBS volume via Secure Copy (SCP). You must upload your files to the `/mnt/bamboo-ebs` folder or its subfolders, if you want them to be included in the snapshot.

   c. Execute `killall java` — This command kills all agent processes, so that nothing is using the mounted volume.

   d. Execute `jps -vl` — This command displays a list of all java processes running on your instance. There should be no java processes running.

   e. Run `generateSnapshot.sh` — This script unmounts and detaches the volume, before creating a snapshot based on the volume.

   f. Check the elastic instance logs for the Snapshot ID of the snapshot you just created. See **Accessing an Elastic Instance** for instructions on how to access the logs for your elastic instance.

   g. Update the new Snapshot ID in your Elastic Bamboo configuration, as described in **Configuring an Elastic Image to use an EBS snapshot** above.

**Important EBS directories and files**

By convention, Bamboo will attach an EBS device at `/dev/sdh`. This will be mounted at `/mnt/bamboo-ebs`. The contents of the standard structure are:

- `/bin/customiseInstance.sh` - This script is run on startup of an elastic instance. We recommend that you do not customize this script, as it is overwritten when `rewarmEbsSnapshot.sh` is run.
- `/bin/customise-extras.sh` - This script is run on startup of an elastic instance as the root (as opposed to being run as the Bamboo user). This script is safe to customize, as it will never be overwritten. You can customize this script to automate processes such as setting up your database, move files to custom locations on the instance, etc.
- `/profile-extras.sh` - This script gets appended to the profile that is run under the Bamboo user (as opposed to being run as the root). It is useful for setting up environment variables.
- bamboo-agent/bamboo-agent.cfg.xml - This configuration file modifies the build working directory to point to build working directory on the EBS volume.
- bamboo-agent/build-dir - This is the build working directory.
- maven/build.properties - This properties file is copied to /home/bamboo on startup of an elastic instance. It points the Maven 1 default repository to /mnt/bamboo-elastic-maven/.maven
- maven/.m2/settings.xml - This configuration file is copied to /mnt/bamboo-elastic-maven/.m2/repository.
- tmp-extras - The contents of this directory is copied to /tmp on startup of an elastic instance.

-----

2. Access your elastic instance via SSH (see Accessing an elastic instance for instructions).
3. sudo su -

   a. In this case, the '-' or the '-l' or the '-login' parameters is required, otherwise some of the scripts may fail.
4. Follow the steps below to create an EBS volume and attach it to the elastic instance (steps a & b), upload content to the EBS volume (step c & d), and generate the snapshot (step e & f):

   i. All the scripts mentioned below are available in /opt/bamboo-elastic-agent/bin on Bamboo stock images. You can also download them from here (choose the latest version).
   a. Run createInitialVolume.sh <volume size> — This script creates a EBS volume (where <volume size> is the size of the volume), attaches the volume and mounts it on the elastic instance. For example, createInitialVolume.sh 100 will create a 100GB EBS volume and attach and mount it on the elastic instance.

Populating your EBS volume

This page is intended to complement the instructions for Configuring elastic instances to use the EBS. It lists different methods of for populating your EBS volume, depending on the data you wish to have available in your snapshot.

On this page:
- Uploading Maven 2 repository data
- Uploading Ant repository data
- Setting up PostgreSQL for elastic agents
- Setting up Selenium on elastic agents

Related pages:
- Configuring elastic instances to use the EBS

Uploading Maven 2 repository data

You can upload Maven 2 repository data to your EBS volume, so that it does not have to be downloaded every time an elastic agent (running on an instance which uses the EBS volume) is started.

To populate your EBS snapshot with your Maven repository data, we recommend that you upload it via SCP (see step 5c of the 'Creating your first EBS snapshot' section in Configuring elastic instances to use the EBS). In most cases, you will have a modified settings.xml file if you are using Maven 2. This means that you will need to upload this file and Maven repository data to your EBS volume, rather than populating your volume by running a build.

Uploading Ant repository data

You can upload Ant repository data to your EBS volume, so that it does not have to be downloaded every time an elastic agent (running on an instance which uses the EBS volume) is started.

To populate your EBS snapshot with your Ant repository data, we recommend that you run a build on an elastic agent with a blank EBS volume attached to the elastic instance (see step 2 of the 'Updating your EBS snapshot' section in Configuring elastic instances to use the EBS). This is a faster and more reliable method of populating your volume, if you are using Ant.

Setting up PostgreSQL for elastic agents

You can upload scripts to your EBS volume so that the elastic agent started on any elastic instances which use this EBS volume, will have PostgreSQL automatically installed.

   i. These elastic instances must be started from an elastic image which is associated with an EBS snapshot derived from this EBS volume.

To set up the automatic installation of PostgreSQL on your EBS volume for elastic agents, you will need to create the following script:

setupPostgreSQL.sh
#!/bin/sh
yum install -y postgresql-server
service postgresql initdb
cat > /var/lib/pgsql/data/pg_hba.conf << EOF
local all all trust
host all all 127.0.0.1/32 trust
EOF
/etc/init.d/postgresql start

This script uses the package management tools provided by Fedora to install and configure PostgreSQL on the agent when its started.

1. Uses yum to install the PostgreSQL server packages. Details on the yum tool can be found in the Fedora Software Management Guide.
2. Initializes the PostgreSQL server environment by creating the database directories and default config files.
3. Creates a new pg_hba.conf file which trusts all local connections and all connections coming from localhost.
4. Starts PostgreSQL.

You then need to update the customise-extras.sh file on your EBS volume (see Important EBS Directories and Files) to invoke this script.

Finally, you need to add a custom capability (e.g. postgres=true) to the elastic agents with PostgreSQL installed. You can do this by updating the elastic image configuration that the agents inherit their capabilities from. Read Configuring elastic agent capabilities for detailed instructions.

Setting up Selenium on elastic agents

You can upload scripts to your EBS volume so that the elastic agent started on any elastic instances which use the EBS volume, will be able to run Selenium tests.

These elastic instances must be started from an elastic image which is associated with an EBS snapshot derived from this EBS volume.

To set up elastic agents to support Selenium test, you will need to create the following script:

setupSelenium.sh
#!/bin/sh

centosMajorVersion=5
centosVersion=${centosMajorVersion}

cat >/etc/yum.repos.d/centos-$centosVersion.repo <<EOF
[centos-base]
name=CentOS - Base
mirrorlist=http://mirrorlist.centos.org/?release=${centosVersion}&arch=\$basearch&repo=os
gpgcheck=1
gpgkey=http://mirror.centos.org/centos/RPM-GPG-KEY-CentOS-${centosMajorVersion}
enabled=0

[centos-update]
name=CentOS - Updates
mirrorlist=http://mirrorlist.centos.org/?release=${centosVersion}&arch=\$basearch&repo=updates
gpgcheck=1
gpgkey=http://mirror.centos.org/centos/RPM-GPG-KEY-CentOS-${centosMajorVersion}
enabled=0

EOF

yum -y --enablerepo=centos-base install firefox

yum -y install xorg-x11-server-Xvfb xterm xorg-x11-server-utils twm xorg-x11-fonts-ISO8859-1-75dpi xorg-x11-fonts-Type1

/usr/bin/killall Xvfb

#Start virtual screen
Xvfb :100 -ac -screen 0 1024x768x24 &

This script uses the package management tools provided by Fedora to install Mozilla's Firefox and enough of X to get a VNC (Virtual Network Computing) server running.

1. Uses yum to install the following packages. Details on the yum tool can be found in the Fedora Software Management Guide.
   * vnc-server — the vnc server used by the selenium test server.
   * xorg-x11-server-Xvfb xterm xorg-x11-server-utils twm xorg-x11-fonts— these packages cover the xorg dependencies to get Firefox to run.

2. The script then copies some prepared VNC authentication files into the bamboo home directory and sets their permissions accordingly. These files are:
   * vncpasswd — this is the password file used by the VNC server (copied to /home/bamboo/.vnc/passwd)
   * vncxstartup — this is the script executed by the VNC server when a connection is made (copied to /home/bamboo/.vnc/xstartup)

3. The last step of this script is to manually install Firefox into /opt/firefox (we manually install Firefox because the package that would be installed by the Fedora 8 package management appears to be outdated).
   * The tar is extracted to the appropriate directory
   * The .bashrc file is customized to include the Firefox directory when searching for libraries. This is so Firefox will be able to find its libraries.

You then need to update the customise-extras.sh file on your EBS volume (see Important EBS Directories and Files) to invoke this script.

Finally, you need to add a custom capability (e.g. selenium=true) to the elastic agents with PostgreSQL installed. You can do this by updating the elastic image configuration that the agents inherit their capabilities from. Read Configuring elastic agent capabilities for detailed instructions.
1. Configuring Elastic Bamboo v6.1

Elastic Bamboo allows you to use computing resources from the Amazon Elastic Compute Cloud (EC2) to run builds. Elastic Bamboo uses a remote agent AMI (Amazon Machine Image) to create instances of remote agents in the Amazon EC2.

Builds run on these 'elastic agents' in a similar way to how they run on local and remote agents.

⚠️ If you have disabled remote agent support, you must enable it before you can enable Elastic Bamboo. Refer to Disabling and enabling remote agents support for instructions on how to enable remote agent support.

To configure your Amazon Web Services (AWS) account details or settings for Elastic Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. In the left navigation panel, go to Elastic Bamboo > Configuration.
3. Click Edit configuration.
4. Configure settings as described in the sections below.
5. Click Save when finished.

On this page:
- AWS account settings
- Global settings
- EC2 spot instances
- AWS settings
- Automatic elastic instance management

Related pages:
- AWS account for Bamboo
- Configuring elastic instances to use the EBS
- Disabling Elastic Bamboo

AWS account settings

Before you use Elastic Bamboo for the first time in your Bamboo instance, you must enter your Amazon Web Services (AWS) account details into the Bamboo application. If you do not have an AWS account, you must register for one on the AWS registration page before you can enable Elastic Bamboo.

Before you begin:
- Please note, Elastic Bamboo dynamically creates and runs remote agents in the Amazon Elastic Compute Cloud (EC2). Hence, if you choose to use Elastic Bamboo, you will be charged by Amazon for your EC2 compute usage (separately to your Bamboo license fee). These charges will be billed to the AWS account that you provide. Please read Elastic Bamboo Costs for more details.
- Please note, if you change your AWS account details, Bamboo will stop all elastic agents that are currently running.

To set your AWS account details:

You can enter or update your AWS Access Key ID and AWS Secret Access Key as follows:

1. Go to your account; choose My account/console from your user menu at the top right.
2. Click Security credentials.
3. Enter, or update, your AWS Access Key ID.
4. Select the Change AWS Secret Access Key? checkbox, and enter or update your AWS Secret Access Key.
5. Click Save.

Note that your AWS Access Key ID and AWS Secret Access Key are used together to identify you when accessing Amazon EC2 services. If you are unsure what your AWS Account ID and AWS Secret Access Key are, please refer to the Amazon documentation on AWS access identifiers.

Global settings

Elastic Bamboo provides you with a number of global configuration options to help you optimize EC2 usage for your Bamboo job builds. These settings control how the Bamboo server operates and how it manages its elastic instances and agents.

Maximum Number of Elastic Instances

The number of elastic instances that can be running at any one time. You may wish to decrease this value if you are concerned about EC2 compute costs, and you have a large number of concurrent job builds that cannot be supported by your non-elastic agents.

Automatically terminate elastic instance when elastic agent process ends

Controls whether your elastic instances will automatically shut down after the elastic agent processes running on them terminate.

- Shutdown Delay —controls how long an elastic instance will wait before shutting down, after its elastic agent process terminates.
**EC2 spot instances**

Elastic Bamboo provides support for Amazon EC2 Spot Instances. Amazon spot instances allow you to bid on unused EC2 capacity and use it, as long as your bid exceeds the current "Spot price". You can configure Elastic Bamboo to bid for a spot instance of a particular type, and fall back to a regular instance after a set amount of time if no instances are available.

**Enable support for spot instances**
Select this checkbox to enable support for spot instances.

**Fallback to a regular instance after**
The time (in minutes) after which Elastic Bamboo will fall back to using a regular instance, if a spot instance has not become available.

**Your current bid levels (per hour)**
Fill out this table with your bids. The bids are categorized by EC2 instance type and operating system.

**AWS settings**

These settings allow you to specify your AWS configuration settings in Bamboo so that Bamboo can operate elastic instances through your AWS account. This section includes settings that are used to configure elastic instances to work with the Amazon Elastic Block Store (EBS).

Using EBS with your elastic instances can significantly reduce the amount of data transfer required to run a job build, compared with starting a clean elastic instance. To find out more about this feature and how to set it up in Elastic Bamboo, read Configuring elastic instances to use the EBS.

**Upload AWS account identifiers to new elastic instances**
Select to upload the AWS Account Private Key File and Account Certificate File to all new elastic instances started. This is mandatory if you wish to use EBS to store job build information in a snapshot. However, you can also check this option if you are not using EBS (e.g. if you wish upload the AWS account identifiers in order to use Amazon's AWS command line tools).

**Key files location**
Choose how private key and certificate will be provided.

**Account Private Key File**
You must specify the location of this file to use the Amazon EBS with Elastic Bamboo. This file is generated by Amazon.

**Account Certificate File**
You must specify the location of this file to use the Amazon EBS with Elastic Bamboo. This file is generated by Amazon.

If you haven't downloaded an AWS private key file or certificate file to your Bamboo server yet, see IAM best practices on the Amazon page.

**Automatic elastic instance management**

The Automatic Elastic Instance Management feature allows Bamboo to start and shut down elastic instances automatically (based on build queue demands), so that you do not have to perform these action manually. This feature reduces Bamboo administration overhead and can help minimize your overall elastic instance usage costs.

If a job's requirements cannot be met by any available online agents, this feature will start any elastic instance whose elastic agent has the capabilities to execute the job, so that the job's build can be generated. Regardless of how an elastic instance was started, all elastic instances will be shut down based on the settings specified below.

**Elastic Instance Management**
Choose from the following elastic instance management presets. Each of these presets define values for the five criteria described in the 'Custom' user-defined options (below). (Bear in mind that both the 'Aggressive' and 'Passive' presets have trade-offs.)

- **Default** — Balances build queue clearance rates with elastic instance usage costs.
- **Aggressive** — Favors higher build queue clearance rates but with higher elastic instance usage costs.
- **Passive** — Favors lower instance usage costs but with lower build queue clearance rates.
- **Custom** — Choose your own settings, as described below.
- **Disabled** — Disables Bamboo's automatic elastic instance management feature.

**Idle Agent Shutdown Delay**
Specify the number of minutes that an elastic agent must be idle before Bamboo shuts down the elastic instance running that agent.

Elastic instances running in the Amazon EC2 compute cloud are charged in hourly blocks from the time they are started. To maximize usage of elastic instances in a cost-effective manner, Bamboo only performs these checks just prior to the expiry of each hourly block.

**Allowed non-Bamboo instances**
The maximum number of elastic instances allowed on your AWS account that are not controlled by this Bamboo instance. When this limit is exceeded, Bamboo will not start any new instances.

**Maximum Number of Instances to Start at Once**
The maximum number of elastic instances that Bamboo can start in one go. Bamboo only starts this maximum number of elastic instances on a 'per minute' basis.

**Number of Builds in Queue Threshold**
The total number of builds in a queue. When this and all other thresholds have been reached, new elastic instances will be started.

**Number of Elastic Builds in Queue Threshold**
The number of builds in the queue that can be executed on elastic instances. When this and all other thresholds have been reached, new elastic instances will be started.

**Average Queue Time Threshold**
The average number of minutes that job builds have been waiting in a queue. When this and all other thresholds have been reached, new elastic instances will be started.

---

### Configuring Elastic Bamboo v5.14

Elastic Bamboo allows you to use computing resources from the Amazon Elastic Compute Cloud (EC2) to run builds. Elastic Bamboo uses a remote agent AMI (Amazon Machine Image) to create instances of remote agents in the Amazon EC2.

Builds run on these 'elastic agents' in a similar way to how they run on local and remote agents.

⚠️ If you have disabled remote agent support, you must enable it before you can enable Elastic Bamboo. Refer to Disabling and enabling remote agents support for instructions on how to enable remote agent support.

---

To configure your Amazon Web Services (AWS) account details or settings for Elastic Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. In the left navigation panel, go to Elastic Bamboo > Configuration.
3. Click Edit configuration.
4. Configure settings as described in the sections below.
5. Click Save when finished.

**On this page:**

### Global settings

Elastic Bamboo provides you with a number of global configuration options to help you optimize EC2 usage for your Bamboo job builds. These settings control how the Bamboo server operates and how it manages its elastic instances and agents.
Maximum Number of Elastic Instances

The number of elastic instances that can be running at any one time. You may wish to decrease this value if you are concerned about EC2 compute costs, and you have a large number of concurrent job builds that cannot be supported by your non-elastic agents.

Automatically terminate elastic instance when elastic agent process ends

Controls whether your elastic instances will automatically shut down after the elastic agent processes running on them terminate.

- **Shutdown Delay** —controls how long an elastic instance will wait before shutting down, after its elastic agent process terminates.

EC2 spot instances

Elastic Bamboo provides support for Amazon EC2 Spot Instances. Amazon spot instances allow you to bid on unused EC2 capacity and use it, as long as your bid exceeds the current "Spot price". You can configure Elastic Bamboo to bid for a spot instance of a particular type, and fall back to a regular instance after a set amount of time if no instances are available.

Enable support for spot instances

Select this checkbox to enable support for spot instances.

Fallback to a regular instance after

The time (in minutes) after which Elastic Bamboo will fall back to using a regular instance, if a spot instance has not become available.

Your current bid levels (per hour)

Fill out this table with your bids. The bids are categorized by EC2 instance type and operating system.

AWS settings

These settings allow you to specify your AWS configuration settings in Bamboo so that Bamboo can operate elastic instances through your AWS account. This section includes settings that are used to configure elastic instances to work with the Amazon Elastic Block Store (EBS).

Using EBS with your elastic instances can significantly reduce the amount of data transfer required to run a job build, compared with starting a clean elastic instance. To find out more about this feature and how to set it up in Elastic Bamboo, read Configuring elastic instances to use the EBS.

Upload AWS account identifiers to new elastic instances

Select to upload the AWS Account Private Key File and Account Certificate File to all new elastic instances started. This is mandatory if you wish to use EBS to store job build information in a snapshot. However, you can also check this option if you are not using EBS (e.g. if you wish upload the AWS account identifiers in order to use Amazon's AWS command line tools).

Key files location

Choose how private key and certificate will be provided.

Account Private Key File

You must specify the location of this file to use the Amazon EBS with Elastic Bamboo. This file is generated by Amazon.

Account Certificate File

You must specify the location of this file to use the Amazon EBS with Elastic Bamboo. This file is generated by Amazon.

If you haven't downloaded an AWS private key file or certificate file to your Bamboo server yet, see IAM best practices on the Amazon page.

Automatic elastic instance management

The Automatic Elastic Instance Management feature allows Bamboo to start and shut down elastic instances automatically (based on build queue demands), so that you do not have to perform these actions manually. This feature reduces Bamboo administration overhead and can help minimize your overall elastic instance usage costs.

If a job's requirements cannot be met by any available online agents, this feature will start any elastic instance whose elastic agent has the capabilities to execute the job, so that the job's build can be generated. Regardless of how an elastic instance was started, all elastic instances will be shut down based on the settings specified below.
Elastic Instance Management

Choose from the following elastic instance management presets. Each of these presets define values for the five criteria described in the 'Custom' user-defined options (below). (Bear in mind that both the 'Aggressive' and 'Passive' presets have trade-offs.)

- **Default** — Balances build queue clearance rates with elastic instance usage costs.
- **Aggressive** — Favors higher build queue clearance rates but with higher elastic instance usage costs.
- **Passive** — Favors lower instance usage costs but with lower build queue clearance rates.
- **Custom** — Choose your own settings, as described below.
- **Disabled** — Disables Bamboo’s automatic elastic instance management feature.

Idle Agent Shutdown Delay

Specify the number of minutes that an elastic agent must be idle before Bamboo shuts down the elastic instance running that agent.

Elastic instances running in the Amazon EC2 compute cloud are charged in hourly blocks from the time they are started. To maximize usage of elastic instances in a cost-effective manner, Bamboo only performs these checks just prior to the expiry of each hourly block.

Allowed non-Bamboo instances

The maximum number of elastic instances allowed on your AWS account that are not controlled by this Bamboo instance. When this limit is exceeded, Bamboo will not start any new instances.

Maximum Number of Instances to Start at Once

The maximum number of elastic instances that Bamboo can start in one go. Bamboo only starts this maximum number of elastic instances on a 'per minute' basis.

Number of Builds in Queue Threshold

The total number of builds in a queue. When this and all other thresholds have been reached, new elastic instances will be started.

Number of Elastic Builds in Queue Threshold

The number of builds in the queue that can be executed on elastic instances. When this and all other thresholds have been reached, new elastic instances will be started.

Average Queue Time Threshold

The average number of minutes that job builds have been waiting in a queue. When this and all other thresholds have been reached, new elastic instances will be started.

Configuring Elastic Bamboo v6.0

Elastic Bamboo allows you to use computing resources from the Amazon Elastic Compute Cloud (EC2) to run builds. Elastic Bamboo uses a remote agent AMI (Amazon Machine Image) to create instances of remote agents in the Amazon EC2.

Builds run on these 'elastic agents' in a similar way to how they run on local and remote agents.

*If you have disabled remote agent support, you must enable it before you can enable Elastic Bamboo. Refer to [Disabling and enabling remote agents support](#) for instructions on how to enable remote agent support.*

To configure your Amazon Web Services (AWS) account details or settings for Elastic Bamboo:

1. Click the ![icon](#)
   icon in the Bamboo header and choose Overview.
2. In the left navigation panel, go to Elastic Bamboo > Configuration.
3. Click Edit configuration.
4. Configure settings as described in the sections below.
5. Click Save when finished.

### AWS settings

These settings allow you to specify your AWS configuration settings in Bamboo so that Bamboo can operate elastic instances through your AWS account. This section includes settings that are used to configure elastic instances to work with the Amazon Elastic Block Store (EBS).
Using EBS with your elastic instances can significantly reduce the amount of data transfer required to run a job build, compared with starting a clean elastic instance. To find out more about this feature and how to set it up in Elastic Bamboo, read [Configuring elastic instances to use the EBS](#).

### Upload AWS account identifiers to new elastic instances

Select to upload the AWS Account Private Key File and Account Certificate File to all new elastic instances started. This is mandatory if you wish to use EBS to store job build information in a snapshot. However, you can also check this option if you are not using EBS (e.g. if you wish upload the AWS account identifiers in order to use Amazon's AWS command line tools).

### Key files location

Choose how private key and certificate will be provided.

- **Account Private Key File**
  
  You must specify the location of this file to use the Amazon EBS with Elastic Bamboo. This file is generated by Amazon.

- **Account Certificate File**
  
  You must specify the location of this file to use the Amazon EBS with Elastic Bamboo. This file is generated by Amazon.

If you haven't downloaded an AWS private key file or certificate file to your Bamboo server yet, see [IAM best practices](#) on the Amazon page.

### Automatic elastic instance management

The Automatic Elastic Instance Management feature allows Bamboo to start and shut down elastic instances automatically (based on build queue demands), so that you do not have to perform these actions manually. This feature reduces Bamboo administration overhead and can help minimize your overall elastic instance usage costs.

If a job's requirements cannot be met by any available online agents, this feature will start any elastic instance whose elastic agent has the capabilities to execute the job, so that the job's build can be generated. Regardless of how an elastic instance was started, all elastic instances will be shut down based on the settings specified below.

#### Elastic Instance Management

Choose from the following elastic instance management presets. Each of these presets define values for the five criteria described in the 'Custom' user-defined options (below). (Bear in mind that both the 'Aggressive' and 'Passive' presets have trade-offs.)

- **Default** — Balances build queue clearance rates with elastic instance usage costs.
- **Aggressive** — Favors higher build queue clearance rates but with higher elastic instance usage costs.
- **Passive** — Favors lower instance usage costs but with lower build queue clearance rates.
- **Custom** — Choose your own settings, as described below.
- **Disabled** — Disables Bamboo's automatic elastic instance management feature.

#### Idle Agent Shutdown Delay

Specify the number of minutes that an elastic agent must be idle before Bamboo shuts down the elastic instance running that agent.

*Elastic instances running in the Amazon EC2 compute cloud are charged in hourly blocks from the time they are started. To maximize usage of elastic instances in a cost-effective manner, Bamboo only performs these checks just prior to the expiry of each hourly block.*

#### Allowed non-Bamboo instances

The maximum number of elastic instances allowed on your AWS account that are not controlled by this Bamboo instance. When this limit is exceeded, Bamboo will not start any new instances.

#### Maximum Number of Instances to Start at Once

The maximum number of elastic instances that Bamboo can start in one go. Bamboo only starts this maximum number of elastic instances on a 'per minute' basis.

#### Number of Builds in Queue Threshold

The total number of builds in a queue. When this and all other thresholds have been reached, new elastic instances will be started.

#### Number of Elastic Builds in Queue Threshold

The number of builds in the queue that can be executed on elastic instances. When this and all other thresholds have been reached, new elastic instances will be started.

#### Average Queue Time Threshold

The average number of minutes that job builds have been waiting in a queue. When this and all other thresholds have been reached, new elastic instances will be started.
Managing Elastic Bamboo

The following pages and the related sub-pages contain information on managing your elastic image, instances and agents.

- **Managing your elastic images** — please see this page and the related sub-pages for detailed information about Elastic Bamboo images in Bamboo. This includes instructions on how to view and customize the capabilities of your Elastic Bamboo images.
- **Managing your elastic instances** — please see this page and the related sub-pages for detailed information about Elastic Bamboo instances in Bamboo. This includes instructions on how to view, start, stop and access an elastic instance.
- **Managing your elastic agents** — please see this page and the related sub-pages for detailed information about Elastic Bamboo remote agent instances in Bamboo. This includes instructions on how to view and disable an elastic instance.

Managing your elastic images

An **elastic image** is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer's boot hard drive and elastic instances would be the software that runs on this operating system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an **AMI ID**.

You can **associate multiple elastic images** with a Bamboo server. One **default shared image** is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

You can also **create your own custom elastic images**.

If you haven’t provided your AWS details in Bamboo, you must set them before you can work with elastic instances. For more information, see [Configuring Elastic Bamboo](#).

- To view an elastic image, including the image properties, capabilities and the jobs that an image can build, see [Viewing an elastic image](#).
- To associate an elastic image with your Bamboo installation, see [Managing your elastic image configurations](#).
- To create your own custom elastic image, see [Creating a custom elastic image](#).

Viewing an elastic image

An **elastic image** is similar to an agent, so the 'Image' page closely resembles the 'Agent' page. A number of functions available for agents are also available for images.

- **Viewing an elastic image’s capabilities** — your image has capabilities, similar to how agents have capabilities. Read more about [viewing an agent's capabilities](#).
- **Viewing the jobs that an image can build** — you can also view the jobs that an image is capable of building (using the elastic agent created from the image), in a similar way to how you view the jobs that an agent is capable of building. Read more about [viewing the jobs that an agent can build](#) and determining which agents can build which jobs.

- **Managing your elastic images**

To view an image:

1. Click the ![icon](image.png) in the Bamboo header and choose **Overview**.
2. Click **Image Configurations** in the left navigation panel (under ‘Elastic Bamboo’).
3. Click the name, or **View**, for the image that you want to view.

**Name**
The name of the image.

**AMI ID**
The Amazon Machine Image identifier that uniquely identifies the image.

**EBS Snapshot ID**
The ID of the EBS Snapshot that you have associated with this image. See [Configuring elastic instances to use the EBS and Managing your elastic image configurations](#) for more information on how to use EBS with Elastic Bamboo.

**Instance Type**
The instance type of new instances started from this image. Read more about [Amazon instance types](#).

**Availability Zone Preference**
New instances started from this image will be run in the Amazon availability zone named here.

**Active Instances**
The number of currently active instances that were started from this image.
**Manage Elastic Image Configurations**

### Maven 2.1 Image

**Elastic Image Configuration**

- **Name**: Maven 2.1 Image
  - Contains Maven 2.1 and the necessary bits for Selenium 2
- **AMI ID**: ami-0ab64663
- **EBS Snapshot ID**: snap-68204c00
- **Instance Type**: High-CPU Medium
- **Availability Zone**: Default (chosen by EC2)
- **Preference**: 
- **Active Instances**: 13

**Elastic Image Capabilities**

A capability is a feature of an agent. There are 3 types of capabilities: builders, JDKs and custom. You can use this page to view, add and delete capabilities associated with this Elastic Image Configuration. Any existing elastic instances will need to be restarted to pick up these changes.

The following capabilities exist on Elastic Agents running on an instance of this Image:

#### Custom

"Custom" capabilities are key-value pairs that define particular characteristics of an agent (e.g., 'operating system=Windows/XP', 'fast builds=true'). For an agent to be able to build a job, both the 'Key' and 'Value' must match the job's requirements.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>bamboo.functionalTest</td>
<td>true</td>
<td>View</td>
</tr>
</tbody>
</table>

#### Builder

"Builder" capabilities define the builders which are available to your build plans.

<table>
<thead>
<tr>
<th>Builder Label</th>
<th>Path</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ant (Ant)</td>
<td>/opt/apache-ant-1.7.1</td>
<td>View</td>
</tr>
<tr>
<td>Maven 2 (Maven 2.x)</td>

Add Capability
Managing your elastic image configurations

An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer's boot hard drive and elastic instances would be the software that runs on this operation system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an AMI ID.

You can associate multiple elastic images with a Bamboo server. One default shared image is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

You can also create your own custom elastic images.

On this page:
- Associating custom elastic images with Bamboo
- Creating elastic images with custom agent capabilities

Related pages:
- Managing your elastic images

Associating custom elastic images with Bamboo

Associating a custom elastic image with your Bamboo installation allows you to start elastic instances with capabilities that are different from those inherited from the default image. For example, you may wish to associate a Ubuntu operating system-based elastic image with your Bamboo installation, so that you can run Ubuntu-related tests on the instances started from that image.

Once you have associated a custom elastic image with Bamboo, the settings for your elastic image are stored as an elastic image configuration.

To associate a custom image with Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Image Configurations in the left navigation panel (under 'Elastic Bamboo').
3. Enter the details of your custom elastic image in the panel under 'Create Elastic Image Configuration':

   **Name**
   The name of your custom elastic image. If you created your own custom image, you should have named it in step 6 of the Creating a custom elastic image instructions. You can also view the image name via the AWS console.

   **Description**
   A description for your image, which is used in Bamboo only.

   **AMI ID**
   The AMI ID obtained as an output from step 6 of the Creating a custom elastic image instructions. You can also view the AMI IDs of elastic images via the AWS console.

   **Automatically attach an Amazon Elastic Block Store (EBS) volume to new elastic instances**
   Select this option if you want the elastic instances started from this image to use the EBS. Read more about Configuring elastic instances to use the EBS.

   **EBS Snapshot ID** — Specify the EBS Snapshot ID of the EBS volume that you wish to attach to new instances.

   **Instance Type**
   The instance type for new instances started from this image. Amazon offers a number of instance types that provide different computing capacity. Read more about Amazon EC2 instance types.

   **Virtual Private Cloud Subnet**
   The Subnet of the Virtual Private Cloud where your Elastic Bamboo agent will start up. Choose multiple subnets from the list to enable Bamboo to automatically switch between Availability Zones when starting agents. This reduces the chance of a build failing because of a lack of available resources in a particular zone. For more about VPC, see the Amazon VPC FAQ.

   **Availability Zone**

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
The availability zone used to start your new instances from this image in (e.g. if you wish to use Elastic Bamboo with reserved instances). We recommend that you select "Default (chosen by EC2)" to allow Amazon to select the best zone for your instance. Read more about Amazon EC2 availability zones.

**Product**
The EC2 product name.

**Screenshot: Manage your Elastic Image Configurations**

Creating elastic images with custom agent capabilities

You can customize the agent capabilities of an elastic image that is already associated with Bamboo. The initial process is similar to that of associating a custom elastic image with Bamboo (above). Here, however, you use the AMI ID of an image already associated with Bamboo — most commonly the default image.

To create an elastic image with customized agent capabilities:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Image Configurations in the left navigation panel (under “Elastic Bamboo”).
3. Click the name, or View, for the image that you want to view.
4. Enter the details of your custom elastic image in the panel (under ’Create Elastic Image Configuration’). See the section above for details.
5. You now have a new elastic image configuration based on an existing elastic image. Follow the procedure on Configuring elastic agent capabilities to customize this elastic image’s agent capabilities.

**Managing your elastic image configurations v5.14**

An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer's boot hard drive and elastic instances would be the software that runs on this operating system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an AMI ID.

You can associate multiple elastic images with a Bamboo server. One default shared image is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

You can also create your own custom elastic images.

**Creating elastic images with custom agent capabilities**

You can customize the agent capabilities of an elastic image that is already associated with Bamboo. The initial process is similar to that of associating a custom elastic image with Bamboo (above). Here, however, you use the AMI ID of an image already associated with Bamboo...
To create an elastic image with customized agent capabilities:

1. Click the icon in the Bamboo header and choose **Overview**.
2. Click **Image Configurations** in the left navigation panel (under 'Elastic Bamboo').
3. Click the name, or **View**, for the image that you want to view.
4. Enter the details of your custom elastic image in the panel (under 'Create Elastic Image Configuration'). See the section above for details.
5. You now have a new elastic image configuration based on an existing elastic image. Follow the procedure on **Configuring elastic agent capabilities** to customize this elastic image's agent capabilities.

Creating a custom elastic image

An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer's boot hard drive and elastic instances would be the software that runs on this operating system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an **AMI ID**.

You can **associate multiple elastic images** with a Bamboo server. One **default shared image** is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

At a high level, the process for creating a custom elastic image consists of taking one of the existing Amazon Machine Images (AMIs) available on Amazon EC2, starting an instance of the AMI, customizing the instance and then creating an image from the customized instance. This image can then be used as an elastic image in your Bamboo installation.

Instead of creating a custom image (Linux/UNIX only) consider:

- Using the "Instance setup script" feature to run commands (executed as the root user) before the agent is started. This field is available for every image from the Administration > Image Configurations page. Click the "Edit" link under Operations for the image you want to use.
- Customizing an existing Bamboo image by using Amazon's Elastic Block Store (EBS), as described in **Configuring elastic instances to use the EBS**.

The options above are much simpler than creating a new custom image. If you are having problems, please don't hesitate to contact us for further help.

Before you begin:

- This is not a trivial procedure and chances are you don't need it.
- Please note, Atlassian does not support custom elastic images. Consider customizing the elastic agents started from your stock images instead.
- A number of the EC2 commands in the steps below can be completed using the **AWS console** rather than command line tools (e.g. registering an image). You should use the method you feel most comfortable with.

On this page:

1. Requirements
2. Selecting an existing AMI
3. Starting an instance
4. Accessing your instance
5. Customizing your instance
6. Creating an image of your customized instance
7. Next steps
8. Need more help?

1. Requirements

First ensure that you have set up the following:

- **Amazon Web Services (AWS) account with EC2** — if you are already using Elastic Bamboo, you should already have an AWS account with EC2 set up. If not, please read **Getting started with Elastic Bamboo**.
- **Amazon EC2 API Tools** — you must install the EC2 API tools on your local machine, otherwise you will not be able to start and access your AMI instance. Note: you need Java Runtime Environment to run these tools. You can install the EC2 API tools by executing the following commands:
wget http://s3.amazonaws.com/ec2-downloads/ec2-api-tools.zip
unzip ec2-api-tools.zip

- **Environment Variables** — you must set up the following environment variables on your local machine before creating a custom elastic image:
  - `EC2_HOME` — set this to the path to the installed EC2 API Tools
  - `EC2_CERT` — set this to the path to the certificate assigned to EC2 account
  - `EC2_PRIVATE_KEY` — set this to the path to the private key assigned to your AWS account

- **Registered Key Pair** — you need a registered EC2 key pair, which consists of a private key file and certificate file, to use the EC2 API tools with your AMI instance. If you have previously generated and registered an EC2 key pair (e.g. to use the EC2 API tools), you can re-use it. If you need to generate a new key pair, you can use the following command to do so:

  ```bash
  ec2-add-keypair <key_pair_name>
  ```

  The content of the private key will be displayed in the command-line output on your console. Save this content in a file, starting with the line:

  ```
  --BEGIN RSA PRIVATE KEY--
  ```

  and ending with the line:

  ```
  --END RSA PRIVATE KEY--
  ```

  This private key file will be used to access your AMI instance. Set up the appropriate permissions on the private key file by executing the following command:

  ```bash
  chmod 600 <private_key_file>
  ```

2. **Selecting an existing AMI**

We strongly recommend that you select an existing Linux/UNIX AMI to customize, rather than starting with a blank AMI. When choosing an AMI, decide whether you want to launch **32-bit** or **64-bit** instances from your custom elastic image and select an existing AMI matching your choice.

We recommend the following existing Linux/UNIX AMIs for customization (in order of preference):

<table>
<thead>
<tr>
<th>Source</th>
<th>Description</th>
<th>AMI list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Atlassian</td>
<td>One of the Stock images provided by Atlassian. It is an Amazon image, for either Linux or Windows, updated and prepared for Bamboo, i.e. you will not have to install any Bamboo prerequisites.</td>
<td>Available on your Bamboo instance under Administration/Image Configurations</td>
</tr>
<tr>
<td>Amazon</td>
<td>CentOS-based image provided by Amazon. It does not have any Bamboo prerequisites installed. Typically, you will be better off using the Atlassian AMI.</td>
<td>Amazon's site</td>
</tr>
<tr>
<td>Canonical(Ubuntu)</td>
<td>An official Ubuntu image provided by Canonical (the company behind the Ubuntu Linux project). It does not have any Bamboo prerequisites installed.</td>
<td>Canonical's site</td>
</tr>
</tbody>
</table>

Atlassian's AMIs (and hence, their IDs) may change with each release of Bamboo, including both major and minor releases. To quickly access Atlassian's AMI IDs for your currently-running version of Bamboo, open that Bamboo site in a web browser and access its 'Image Configurations' page (see Managing your Elastic Image Configurations for more information). The AMI IDs of Atlassian's AMIs are labeled with "(stock image)".

If you want to find out the AMI IDs for a version of Bamboo you don't have running or you're starting an image from scratch and you need the image baseline:

2. On the resulting directory page, click the link that represents the version of Bamboo you are currently running. For example, if you are running Bamboo 5.9.7, click on the 5.9.7 link. Another directory page opens, listing a .pom and some additional checksum files.

   ! Do not click on a version number link that contains 'mX', 'rcX' or 'betaX' (where 'X' is a number), since these relate to publicly available developmental releases of Bamboo.

3. Open the atlassian-bamboo-x.x.x.pom file (where x.x.x is your version of Bamboo). The image version/baseline is stored in the `elastic-image.version` tag. For example, this value is "4.2" for Bamboo version 5.9.4.
5. Click on the image version/baseline you found in the `elastic-image.version` tag. On the resulting directory page, the file with `.ami` extension contains all stock image AMI IDs.

3. Starting an instance

After you have selected an existing AMI to customize, the next step is to start an instance of the AMI.

3.1 Starting an instance of Atlassian's default AMI

If you chose to customize Atlassian's default AMI, you will have to start the instance from the admin section of Bamboo. See Starting an elastic instance.

Note that Atlassian's default AMI cannot be started using the command line ec2 tools. This is because, on start up, the Bamboo agent on Atlassian's AMI checks to see if it was started from a Bamboo server, and immediately shuts itself down if it was not.

Once started, see Accessing an elastic instance for details on how to access the running instance.

3.2 Starting an instance from the command line

Use the `ec2-run-instances` command to start your instance, as follows:

```
ec2-run-instances <image_name> -k <key_pair_name>
```

where `<image_name>` is the name of the AMI selected in the previous step and `<key_pair_name>` is the name of the registered key pair generated in '1. Requirements'. The public certificate of this key will be injected into your instance.

For example, if you wanted to start an instance of image `ami-e55bbd8c` using key pair `my-keypair`, you would run the following command:

```
ec2-run-instances ami-e55bbd8c -k my-keypair
```

This command would produce the following command-line output:

```
INSTANCEx i-25b86743 amixe55bbd8c running my-keypair
```

*i-25b86743* is the name of the new instance in the above example. You should note down the name of your new instance, as you will need that to access your instance in the next step.

**Don't forget to shut down unused instances**

Please note that once you start an instance, you will be billed by Amazon for instance uptime. If you decide to abandon the setup of a custom elastic image after this step, please ensure that you shut down your instance via the AWS console.

3.3 Starting an instance from Bamboo

You can also start a fresh, uncustomized image from Bamboo and begin customization. The drawback of this approach is that you have only 40 minutes before Bamboo shuts down your instance. The advantage is that you can customize the agent in a single step (as opposed to having to customize/create image/start from Bamboo/save image again).

4. Accessing your instance

If you started the instance from Bamboo, see Accessing an elastic instance for details on how to access the running instance.

Once your instance is running, you will need to obtain the address of the instance so you can access it. To do this, use the following command:

```
ec2-describe-instances <instance_name>
```

For example, if you wanted to find the address of instance `i-25b86743`, you would enter:
This command would produce the following command-line output similar to this:

```
RESERVATION r-790f7210 121852097033 default
INSTANCE i-25b86743 ami-e55bbd8c
e2-174-129-94-241.compute-1.amazonaws.com
domU-12-31-39-04-38-87.compute-1.internal running elasticbamboo 0
m1.small
2009-06-24T12:36:20+0000 us-east-1c aki-a71cf9ce ari-a51cf9cc
monitoring-disabled
```

The address of the instance in the above example is `ec2-174-129-94-241.compute-1.amazonaws.com`

You can then use this address to access the instance via SSH. See Accessing an elastic instance for instructions. If you are using the example command text from that document, you will need to adjust it as follows:

- replace `/opt/bamboo/home/xml-data/configuration/elasticbamboo.pk` in the example command text with the private key file you generated in '1. Requirements'.
- replace `ec2-68-111-185-197.compute-1.amazonaws.com` in the example command text with the address of your instance.

5. Customizing your instance

Now that you have a running instance, customization steps heavily depend on the operating system you're using. We've prepared separate pages with Linux-specific instructions and Windows-specific instructions.

6. Creating an image of your customized instance

The process of creating a new image varies depending whether you based your image on an instance-store or EBS-root image. You can check your image type via AWS console or using ec2-describe-images.

**Creating an image from EBS-root instances**

See here for instructions: Amazon Tutorial

**Creating an image from instance-store (S3) instances**

The final step is to create an image from your customized instance. To do this, you will require the following information:

- Amazon Account Number
- Access Key ID
- Secret Access Key
- Amazon S3 bucket name that will be used to store image (if you don't have access to Amazon S3, you can sign up on this page.

1. **Transfer Amazon private key file and certificate to your instance**

   Transfer the key files to your instance by running these commands on your local machine:

   ```
   scp -i <private_key_file> $EC2_PRIVATE_KEY
   root@<instance_address>:/mnt
   scp -i <private_key_file> $EC2_CERT root@<instance_address>:/mnt
   ```

   where `<private_key_file>` is the private key file from your local machine created in step 'Registered Key Pair' of 1. Requirements and the `<instance_address>` is the address of your instance from '4. Accessing your Instance'.

2. **Set up EC2_HOME and JAVA_HOME environment variables**

   Set up these environment variables by running the following commands on your instance:

   ```
   ```
export EC2_HOME=<location of your EC2 tools installation>
export EC2_PRIVATE_KEY=/mnt/<ec2_private_key_file>
export EC2_CERT=/mnt/<ec2_certificate_file>
export JAVA_HOME=<path to JRE used to start the agent>

3. You can create an image of your customized instance by using the `ec2-bundle-vol` command, as follows:

```bash
ec2-bundle-vol -c $EC2_CERT -k $EC2_PRIVATE_KEY -u
<amazon_account_number> -p <elastic_image_name> --batch --debug
```

where `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1')

4. Once the image is created, you need to upload it to Amazon S3 by running the command below:

```bash
ec2-upload-bundle -b <s3_bucket_name> -m
/tmp/<elastic_image_name>.manifest.xml -a <access_key_id> -s
<secret_access_key> --retry --debug
```

where `<s3_bucket_name>` and `<access_key_id>` and `<secret_access_key>` are the Amazon S3 bucket name, Access Key ID and Secret Access Key described previously, and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1').

You will then need to register your image with Amazon EC2 by using the `ec2-register` command:

```bash
ec2-register <s3_bucket_name>/<elastic_image_name>.manifest.xml
```

where `<s3_bucket_name>` is the Amazon S3 bucket name described previously and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1'). The output of this command will show the AMI ID of your custom image.

7. Next steps

Now that you have created a custom elastic image, there are **two more steps** that you will need to complete before you can use it.

First, you will need to **associate your custom elastic image with your Bamboo installation** by creating an Elastic Image Configuration. Please note the AMI ID of your new custom image and read **Managing your Elastic Image Configurations** for further instructions.

Secondly, you will need to **configure the capabilities of the elastic agents** that will run on instances started from your image. This is done by adding the appropriate builder, JDK, Perforce and custom capabilities to your elastic image configuration, so that it reflects what your custom elastic image actually can do. For example, if you have created a custom elastic image with JDK 1.6 and Maven 2 installed, you will need to add capabilities for JDK 1.6 and Maven 2 to the elastic image configuration. Read **Configuring Elastic Agent Capabilities** for further instructions.

8. Need more help?

If you need **more help**, there are a number of resources that you can take advantage of:

- **AWS Support Center** — if you are having problems with any of your Amazon services, not specifically related to Bamboo, you can obtain basic support from the AWS Support Center. Note, you will need to sign up for Premium Support to get access to web/phone support.
- **AWS Resource Center** — the AWS Resource Center has links to online documentation, code samples and tools for AWS services.
- **Bamboo Developer Forums** — please feel free to discuss any useful tips or issues regarding this process in the Bamboo Developer Forums.
Creating a custom elastic image - Linux

Atlassian doesn’t provide support for customized images. Bamboo provides flexibility to use customized machine images, but it’s impossible for us to support all individual configurations.

Use Bamboo stock images as the base for all image customizations to ensure a minimal level of consistency of your Elastic Bamboo setup.

5. Customizing your instance

Customizing your instance is the most complicated part of creating a custom elastic image. You need to install the packages that are prerequisites for Bamboo onto your instance (if you didn’t choose the Elastic Bamboo Stock images as your base AMI), deploy Bamboo onto your instance and set up an EC2 environment on your instance.

5.1 Installing Bamboo prerequisite packages

If you selected Atlassian’s AMI as your base AMI in ‘2. Selecting an Existing AMI’, you can skip this step and go to ‘5.2 Adding Customizations’ as this image has been pre-configured for Bamboo. If you have selected a different AMI, you will need to install the following packages onto your instance using the commands shown below:

Amazon EC2 API tools

```
wget http://s3.amazonaws.com/ec2-downloads/ec2-api-tools.zip
unzip ec2-api-tools.zip
mv ec2-api-tools-* /opt/ec2-api-tools
```

Note: if your distribution already contains ec2-api-tools package, you can install it instead.

Java JRE

You need to install a JRE (or JDK) on your instance to be able to run the agent. The preferred way of doing this is to install a package that came with your distribution. For a list of supported JREs, see supported platforms.

5.2 Adding user customizations to your instance

Adding your own customizations is quite a simple process, once you have made it this far.

To add user customizations to your instance:

1. Log into your elastic instance (as previously described in ‘4. Accessing your Instance’).
2. Once you have logged into your elastic instance, you can treat it as a standalone machine and install anything you want. For example, if you want to install Tomcat on an Ubuntu instance you would run `sudo apt-get install tomcat6`, configure it, ensure that your startup scripts are in place, etc, just as you would when installing Tomcat on a standalone machine.
   **Please note however, you cannot customize the operating system of a running instance. If you want to create an instance with a customized operating system (e.g. Ubuntu), you will need to select an AMI with that operating system installed (as previously described in ‘2. Selecting an Existing AMI’).**
3. Everything that you install will be saved in snapshot image created at the end of these instructions (see ‘6. Creating an Image of your Customized Instance’). Any instances started from this image will have all of your user customizations automatically installed.

5.3 Deploying Bamboo onto your instance

Once you have installed the Bamboo pre-requisites on you instance and added your customizations, you can deploy Bamboo elastic bootstrap files onto your instance.

5.3.1 Creating Bamboo user

First, you need to create a ‘bamboo’ user on your instance by running the following command:

```
useradd -m bamboo
```

5.3.2 Downloading agent installer to the instance

Then, install Bamboo Agent binaries as described below. In this case we’re using image version 2.2, you should use the latest version available at https://maven.atlassian.com/content/repositories/atlassian-public/com/atlassian/bamboo/atlassian-bamboo-elastic-image/.
imageVer=2.2
wget https://maven.atlassian.com/content/repositories/atlassian-public/com/atlassian/bamboo/atlassian-bamboo-elastic-image/${imageVer}/atlassian-bamboo-elastic-image-${imageVer}.zip
sudo mkdir -p /opt/bamboo-elastic-agent
sudo unzip -o atlassian-bamboo-elastic-image-${imageVer}.zip -d /opt/bamboo-elastic-agent
sudo chown -R bamboo /opt/bamboo-elastic-agent
sudo chmod -R u+r+w /opt/bamboo-elastic-agent

5.4 Instance configuration

At this stage, you should have a customized instance with Bamboo deployed onto it. The last step in creating a customized instance is to set up an EC2 environment on your instance. Carry out the following steps to set this up:

1. Run the following command on your instance to set permissions on the bamboo user directory:

   ```
   chown -R bamboo:bamboo /home/bamboo/
   ```

2. Configure path variables
   Create a file `profile.sh` in your instance's `/mnt` directory. This file contains the default Elastic Bamboo path configuration settings, as seen below:

   ```
   export JAVA_HOME=<path to JRE used to start the agent>
   export EC2_HOME=<location of your EC2 tools installation>
   export EC2_PRIVATE_KEY=/root/pk.pem
   export EC2_CERT=/root/cert.pem
   export PATH=/opt/bamboo-elastic-agent/bin:$EC2_HOME/bin:$JAVA_HOME/bin:$M2_HOME/bin:$MAVEN_HOME/bin:$ANT_HOME/bin:$PATH
   ```

   If all of the tools on this page were installed in recommended locations, no changes are required. Otherwise, you can update the file as required.

   Once `profile.sh` is correctly customized for your instance, you need to copy it to the `/etc/profile.d` directory by running the following command on your instance in the `/mnt` directory:

   ```
   mv profile.sh /etc/profile.d/bamboo.sh
   ```

3. Configure automatic startup of the Bamboo agent
   You will need to configure your instance to start the Bamboo agent automatically when the instance is started. You can do this by sourcing Bamboo `rc.local` file in `/etc/rc.local` file:

   ```
   . /opt/bamboo-elastic-agent/etc/rc.local
   ```

   Make sure you add this line before the "exit 0" line in your `/etc/rc.local`.

4. Final settings and cleanup
   Finally, create a Bamboo welcome screen and clean up keys on your instance by running the following command:
cp /opt/bamboo-elastic-agent/etc/motd /etc/motd
echo bamboo-<x.x.x>  >> /etc/motd
rm -f /root/firstlogin /etc/ssh/ssh_host_dsa_key
/etc/ssh/ssh_host_dsa_key.pub
/etc/ssh/ssh_host_key /etc/ssh/ssh_host_key.pub
/etc/ssh/ssh_host_rsa_key
/etc/ssh/ssh_host_rsa_key.pub /root/.ssh/authorized_keys
touch /root/firstrun

where <x.x.x> is the Bamboo version you are running (e.g. 4.1.2).

5. Now, follow the instructions from section “Creating an image of your Customized Instance” to create an AMI.
6. Start the image from Bamboo. The agent should come up and download all necessary data to the EC2 instance.
7. Run /opt/bamboo-elastic-agent/bin/prepareInstanceForSaving.sh.
8. Now, follow the instructions from section “Creating an image of your Customized Instance” to create an AMI. That's it, the newly created AMI contains everything you need to start Bamboo Agents.

Note: if you started your instance from Bamboo right at the start, instead of steps 5 & 6, you can just run:
su -c /opt/bamboo-elastic-agent/bin/bamboo-elastic-agent - bamboo

Creating a custom elastic image - Windows

Atlassian doesn't provide support for customized images. Bamboo provides flexibility to use customized machine images, but it's impossible for us to support all individual configurations.

Use Bamboo stock images as the base for all image customizations to ensure a minimal level of consistency of your Elastic Bamboo setup.

To perform the tasks listed below, log in to your instance with an Administrator account using Remote Desktop Client.

Setting up the user account

Create the user account that will be used by the Bamboo agent. The account name is up to you, I will use Bamboo in the examples below. All builds running on your machine will use this account. It can be a regular user (i.e. it does not need to be a Power User or Administrator, unless your builds require it). Set up a password for that user. The default user on a Windows image has a user name of Bamboo with a password of Atlassian1.

Important: by default, a newly created user should be denied remote login rights (which is as we want it to be). To be on the safe side, please make sure that you indeed cannot log in using that user’s credentials (unless you change the credentials to non-default ones).

If your builds are not headless (i.e. they show/manipulate windows, like Selenium does), click here for additional instructions
You'll need to set up autologin for your Bamboo account (don't worry, this will not let remote users in). To do this, run control userpasswords2 and uncheck User must enter a user name and password to enter this computer.

Setting up the firewall

Reconfigure the Windows firewall to accept TCP connections on port 26224. No other inbound connections are necessary for Bamboo.

You don’t need to worry about changing the EC2 security group setting for this port. Bamboo will set it up automatically:
Installing the required software

1. Install a supported Oracle Java version. See Supported platforms.
2. Download the latest version of agent installer zip from this location (at the time this guide was written, the latest version was this). Unpack it to a desired location, we suggest using `C:\opt\bamboo-elastic-agent` to match stock images distributed with Bamboo.
3. A batch file should launch with your Windows instance startup. In order to do this, use the Windows Task Scheduler (Start > Administrative Tools > Task Scheduler), and set up a new Action task of "Start a program" with the `<PATH TO YOUR BATCH FILE>` as the Details:

   ```
   Start a program
   C:\opt\bamboo-elastic-agent\bin\bamboo-elastic-agent.bat
   ```
Remember to select **Run whether user is logged on or not** in the “General” tab:

And appropriately define the Trigger task so that the agent starts up only after the network connection is up and running:

The task manager will warn you that the account needs to be able to log in as a batch job. Make sure the “Log on as batch job” policy is set for the user. This policy is accessible by opening the **Control Panel > Administrative Tools > Local Security Policy**. In the Local Security Policy window, click **Local Policies > User Rights Assignment > Log on as a batch job**.

**Enabling EBS usage on the instance**

Starting with Bamboo 5, you’ll be able to use custom Elastic Block Storage with your Windows instances. To do that, you need to change the SAN policy on your instance, otherwise the disks will be attached in ‘Offline’ state with status text “the disk is offline because of policy set by an administrator”.

You can change the SAN policy using the Diskpart utility. Run **Diskpart**, type

```
san policy=OnlineAll
```

and press Enter. You can then quit **Diskpart**; the new policy will now be active.
Testing

The easiest way to check if everything is set up correctly is to run the task you've defined using Windows Task Scheduler (Start > Administrative Tools > Task Scheduler). Right-click on the task and select Run. Always test the script using the Task Scheduler; if you run the script manually, you'll use Administrator account, which is not what we want.

Look for the `%USERPROFILE%/bamboo-elastic-agent.out` file. If it exists and contains an error message stating that agent was not run within an EC2 instance started by Bamboo Server, you've successfully completed the customization.

Run `c:\opt\bamboo-elastic-agent\bin\prepareInstanceForSaving.bat`

Bundle your instance. Make a note of the AMI id of the new image.

Start your image from Bamboo

If you fail to complete the following steps within ~40 minutes, Bamboo will shut down your instance, so remember to save your work if you're running out of time (i.e. create an interim image).

In Bamboo, define an image configuration for the image you've just created, and start it from Bamboo. If everything went well, the agent will start together with the instance. It will perform the following steps:

- Update `/opt/bamboo-elastic-agent` directory structure by creating additional directories. If they appeared, Java is working correctly on that machine and the connection to S3 is working.
- Start the agent, which will create the Bamboo Agent Home directory and populate it with data pulled from the Bamboo server.

If everything went well, you should see the agent appear in the Bamboo instance list. Congratulations, you have a working Bamboo agent.

Because the agent has just synchronized itself with the Bamboo server (because it has downloaded all the jars exactly matching what you have on your server), as an extra step, you may want to save that state to speed up future instance startup and reduce bandwidth usage.

To do that, run `c:\opt\bamboo-elastic-agent\bin\prepareInstanceForSaving.bat`

save the image, define a new image configuration, kill the instance, and try running it from Bamboo.

.Creating a custom elastic image v5.14

Atlassian doesn't provide support for customized images. Bamboo provides flexibility to use customized machine images,
An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer's boot hard drive and elastic instances would be the software that runs on this operation system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an AMI ID.

You can associate multiple elastic images with a Bamboo server. One default shared image is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

At a high level, the process for creating a custom elastic image consists of taking one of the existing Amazon Machine Images (AMIs) available on Amazon EC2, starting an instance of the AMI, customizing the instance and then creating an image from the customized instance. This image can then be used as an elastic image in your Bamboo installation.

Instead of creating a custom image (Linux/UNIX only) consider:

- Using the "Instance setup script" feature to run commands (executed as the root user) before the agent is started. This field is available for every image from the Administration > Image Configurations page. Click the "Edit" link under Operations for the image you want to use.
- Customizing an existing Bamboo image by using Amazon's Elastic Block Store (EBS), as described in Configuring elastic instances to use the EBS.

The options above are much simpler than creating a new custom image. If you are having problems, please don't hesitate to contact us for further help.

Before you begin:

- This is not a trivial procedure and chances are you don't need it.
- Please note, Atlassian does not support custom elastic images. Consider customizing the elastic agents started from your stock images instead.
- A number of the EC2 commands in the steps below can be completed using the AWS console rather than command line tools (e.g. registering an image). You should use the method you feel most comfortable with.

On this page:
1. Requirements
2. Selecting an existing AMI
3. Starting an instance
4. Accessing your instance
5. Customizing your instance
6. Creating an image of your customized instance
7. Next steps
8. Need more help?

**1. Requirements**

First ensure that you have set up the following:

- **Amazon Web Services (AWS) account with EC2** — if you are already using Elastic Bamboo, you should already have an AWS account with EC2 set up. If not, please read Getting started with Elastic Bamboo.
- **Amazon EC2 API Tools** — you must install the EC2 API tools on your local machine, otherwise you will not be able to start and access your AMI instance. Note: you need Java Runtime Environment to run these tools. You can install the EC2 API tools by executing the following commands:

```bash
wget http://s3.amazonaws.com/ec2-downloads/ec2-api-tools.zip
unzip ec2-api-tools.zip
```

- **Environment Variables**— you must set up the following environment variables on your local machine before creating a custom elastic image:
  - `EC2_HOME` — set this to the path to the installed EC2 API Tools
  - `EC2_CERT` — set this to the path to the certificate assigned to EC2 account
  - `EC2_PRIVATE_KEY` — set this to the path to the private key assigned to your AWS account
- **Registered Key Pair**— you need a registered EC2 key pair, which consists of a private key file and certificate file, to use the EC2 API tools with your AMI instance. If you have previously generated and registered an EC2 key pair (e.g. to use the EC2 API tools), you can re-use it. If you need to generate a new key pair, you can use the following command to do so:
ec2-add-keypair <key_pair_name>

The content of the private key will be displayed in the command-line output on your console. Save this content in a file, starting with the line:

"--BEGIN RSA PRIVATE KEY--"

and ending with the line:

"--END RSA PRIVATE KEY--"

This private key file will be used to access your AMI instance. Set up the appropriate permissions on the private key file by executing the following command:

chmod 600 <private_key_file>

2. Selecting an existing AMI

We strongly recommend that you select an existing Linux/UNIX AMI to customize, rather than starting with a blank AMI. When choosing an AMI, decide whether you want to launch 32-bit or 64-bit instances from your custom elastic image and select an existing AMI matching your choice.

We recommend the following existing Linux/UNIX AMIs for customization (in order of preference):

<table>
<thead>
<tr>
<th>Source</th>
<th>Description</th>
<th>AMI list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Atlassian</td>
<td>One of the Stock images provided by Atlassian. It is an Amazon image, for either Linux or Windows, updated and prepared for Bamboo, i.e. you will not have to install any Bamboo prerequisites.</td>
<td>Available on your Bamboo instance under Administration/Image Configurations</td>
</tr>
<tr>
<td>Amazon</td>
<td>CentOS-based image provided by Amazon. It does not have any Bamboo prerequisites installed. Typically, you will be better off using the Atlassian AMI.</td>
<td>Amazon's site</td>
</tr>
<tr>
<td>Canonical(Ubuntu)</td>
<td>An official Ubuntu image provided by Canonical (the company behind the Ubuntu Linux project). It does not have any Bamboo prerequisites installed.</td>
<td>Canonical's site</td>
</tr>
</tbody>
</table>

Atlassian's AMIs (and hence, their IDs) may change with each release of Bamboo, including both major and minor releases. To quickly access Atlassian's AMI IDs for your currently-running version of Bamboo, open that Bamboo site in a web browser and access its 'Image Configurations' page (see Managing your Elastic Image Configurations for more information). The AMI IDs of Atlassian's AMIs are labeled with "(stock image)".

If you want to find out the AMI IDs for a version of Bamboo you don't have running or you're starting an image from scratch and you need the image baseline:

2. On the resulting directory page, click the link that represents the version of Bamboo you are currently running. For example, if you are running Bamboo 5.9.7, click on the 5.9.7 link. Another directory page opens, listing a .pom and some additional checksum files.
   - Do not click on a version number link that contains 'mX', 'rcX' or 'betaX' (where 'X' is a number), since these relate to publicly available developmental releases of Bamboo.
3. Open the atlassian-bamboo-x.x.x.pom file (where x.x.x) is your version of Bamboo). The image version/baseline is stored in the elastic-image.version tag. For example, this value is "4.2" for Bamboo version 5.9.4.
5. Click on the image version/baseline you found in the elastic-image.version tag. On the resulting directory page, the file with the .pom extension contains all stock image AMI IDs.

3. Starting an instance

After you have selected an existing AMI to customize, the next step is to start an instance of the AMI.

3.1 Starting an instance of Atlassian's default AMI

If you chose to customize Atlassian's default AMI, you will have to start the instance from the admin section of Bamboo. See Starting an elastic instance.

Note that Atlassian's default AMI cannot be started using the command line ec2 tools. This is because, on start up, the Bamboo agent on Atlassian's AMI checks to see if it was started from a Bamboo server, and immediately shuts itself down if it was not.

Once started, see Accessing an elastic instance for details on how to access the running instance.
3.2 Starting an instance from the command line

Use the `ec2-run-instances` command to start your instance, as follows:

```
ec2-run-instances <image_name> -k <key_pair_name>
```

where `<image_name>` is the name of the AMI selected in the previous step and `<key_pair_name>` is the name of the registered key pair generated in '1. Requirements'. The public certificate of this key will be injected into your instance.

For example, if you wanted to start an instance of image ami-e55bbd8c using key pair my-keypair, you would run the following command:

```
ec2-run-instances ami-e55bbd8c -k my-keypair
```

This command would produce the following command-line output:

```
INSTANCE i-25b86743 ami-e55bbd8c running my-keypair
```

`i-25b86743` is the name of the new instance in the above example. You should note down the name of your new instance, as you will need that to access your instance in the next step.

3.3 Starting an instance from Bamboo

You can also start a fresh, uncustomized image from Bamboo and begin customization. The drawback of this approach is that you have only 40 minutes before Bamboo shuts down your instance. The advantage is that you can customize the agent in a single step (as opposed to having to customize/create image/start from Bamboo/save image again).

4. Accessing your instance

Once your instance is running, you will need to obtain the address of the instance so you can access it. To do this, use the following command:

```
ec2-describe-instances <instance_name>
```

For example, if you wanted to find the address of instance i-25b86743, you would enter:

```
ec2-describe-instances i-25b86743
```

This command would produce the following command-line output similar to this:

```
RESERVATION r-790f7210 121852097033 default
INSTANCE i-25b86743 ami-e55bbd8c
c2-174-129-94-241.compute-1.amazonaws.com
domU-12-31-39-04-38-87.compute-1.internal running elasticbamboo 0
m1.small
2009-06-24T12:36:20+0000 us-east-1c aki-a71cf9ce ari-a51cf9cc
monitoring-disabled
```

The address of the instance in the above example is `ec2-174-129-94-241.compute-1.amazonaws.com`

Don't forget to shut down unused instances

Please note that once you start an instance, you will be billed by Amazon for instance uptime. If you decide to abandon the setup of a custom elastic image after this step, please ensure that you shut down your instance via the AWS console.

If you started the instance from Bamboo, see Accessing an elastic instance for details on how to access the running instance.
You can then use this address to access the instance via SSH. See Accessing an elastic instance for instructions. If you are using the example command text from that document, you will need to adjust it as follows:

- replace `/opt/bamboo/home/xml-data/configuration/elasticbamboo.pk` in the example command text with the private key file you generated in 1. Requirements.
- replace `ec2-68-111-185-197.compute-1.amazonaws.com` in the example command text with the address of your instance.

5. Customizing your instance

Now that you have a running instance, customization steps heavily depend on the operating system you're using. We've prepared separate pages with Linux-specific instructions and Windows-specific instructions.

6. Creating an image of your customized instance

The process of creating a new image varies depending whether you based your image on an instance-store or EBS-root image. You can check your image type via AWS console or using `ec2-describe-images`.

Creating an image from EBS-root instances

See here for instructions: Amazon Tutorial

Creating an image from instance-store (S3) instances

The final step is to create an image from your customized instance. To do this, you will require the following information:

- Amazon Account Number
- Access Key ID
- Secret Access Key
- Amazon S3 bucket name that will be used to store image (if you don't have access to Amazon S3, you can sign up on this page.)

1. Transfer Amazon private key file and certificate to your instance

   Transfer the key files to your instance by running these commands on your local machine:

   ```
   scp -i <private_key_file> $EC2_PRIVATE_KEY root@<instance_address>:/mnt
   scp -i <private_key_file> $EC2_CERT root@<instance_address>:/mnt
   ```

   where `<private_key_file>` is the private key file from your local machine created in step 'Registered Key Pair' of 1. Requirements and the `<instance_address>` is the address of your instance from 4. Accessing your Instance.

2. Set up `EC2_HOME` and `JAVA_HOME` environment variables

   Set up these environment variables by running the following commands on your instance:

   ```
   export EC2_HOME=<location of your EC2 tools installation>
   export EC2_PRIVATE_KEY=/mnt/<ec2_private_key_file>
   export EC2_CERT=/mnt/<ec2_certificate_file>
   export JAVA_HOME=<path to JRE used to start the agent>
   ```

3. You can create an image of your customized instance by using the `ec2-bundle-vol` command, as follows:

   ```
   ec2-bundle-vol -c $EC2_CERT -k $EC2_PRIVATE_KEY -u
   <amazon_account_number> -p <elastic_image_name> --batch --debug
   ```

   where `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1')

4. Once the image is created, you need to upload it to Amazon S3 by running the command below:

   ```
   ec2-upload-bundle -b <s3_bucket_name> -m
   /tmp/<elastic_image_name>.manifest.xml -a <access_key_id> -s
   <secret_access_key> --retry --debug
   ```
where `<s3_bucket_name>`, `<access_key_id>` and `<secret_access_key>` are the Amazon S3 bucket name, Access Key ID and Secret Access Key described previously, and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. "CustomImage1").

You will then need to register your image with Amazon EC2 by using the `ec2-register` command:

```
ec2-register <s3_bucket_name>/<elastic_image_name>.manifest.xml
```

where `<s3_bucket_name>` is the Amazon S3 bucket name described previously and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. "CustomImage1"). The output of this command will show the AMI ID of your custom image.

### 7. Next steps

Now that you have created a custom elastic image, there are **two more steps** that you will need to complete before you can use it.

First, you will need **to associate your custom elastic image with your Bamboo installation** by creating an Elastic Image Configuration. Please note the AMI ID of your new custom image and read [Managing your Elastic Image Configurations](#) for further instructions.

Secondly, you will need to **configure the capabilities of the elastic agents** that will run on instances started from your image. This is done by assigning the appropriate builder, JDK, Perforce and custom capabilities to your elastic image configuration, so that it reflects what your custom elastic image actually can do. For example, if you have created a custom elastic image with JDK 1.6 and Maven 2 installed, you will need to add capabilities for JDK 1.6 and Maven 2 to the elastic image configuration. Read [Configuring Elastic Agent Capabilities](#) for further instructions.

### 8. Need more help?

If you need more help, there are a number of resources that you can take advantage of:

- **AWS Support Center** — if you are having problems with any of your Amazon services, not specifically related to Bamboo, you can obtain basic support from the AWS Support Center. Note, you will need to sign up for Premium Support to get access to web/phone support.
- **AWS Resource Center** — the AWS Resource Center has links to online documentation, code samples and tools for AWS services.
- **Bamboo Developer Forums** — please feel free to discuss any useful tips or issues regarding this process in the Bamboo Developer Forums.

---

**Creating a custom elastic image v5.15**

Atlassian doesn't provide support for customized images. Bamboo provides flexibility to use customized machine images, but it's impossible for us to support all individual configurations.

Use Bamboo stock images as the base for all image customizations to ensure a minimal level of consistency of your Elastic Bamboo setup.

An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer's boot hard drive and elastic instances would be the software that runs on this operation system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an AMI ID.

You can associate multiple elastic images with a Bamboo server. One default shared image is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

At a high level, the process for creating a custom elastic image consists of taking one of the existing Amazon Machine Images (AMIs) available on Amazon EC2, starting an instance of the AMI, customizing the instance and then creating an image from the customized instance. This image can then be used as an elastic image in your Bamboo installation.

Instead of creating a custom image (Linux/UNIX only) consider:

- Using the "Instance setup script" feature to run commands (executed as the root user) before the agent is started. This field is available for every image from the Administration > Image Configurations page. Click the "Edit" link under Operations for the image you want to use.
Customizing an existing Bamboo image by using Amazon's Elastic Block Store (EBS), as described in Configuring elastic instances to use the EBS.

The options above are much simpler than creating a new custom image. If you are having problems, please don’t hesitate to contact us for further help.

Before you begin:

- This is not a trivial procedure and chances are you don’t need it.
- Please note, Atlassian does not support custom elastic images. Consider customizing the elastic agents started from your stock images instead.
- A number of the EC2 commands in the steps below can be completed using the AWS console rather than command line tools (e.g. registering an image). You should use the method you feel most comfortable with.

### On this page:

1. Requirements
2. Selecting an existing AMI
3. Starting an instance
4. Accessing your instance
5. Customizing your instance
6. Creating an image of your customized instance
7. Next steps
8. Need more help?

---

### 1. Requirements

First ensure that you have set up the following:

- **Amazon Web Services (AWS) account with EC2** — if you are already using Elastic Bamboo, you should already have an AWS account with EC2 set up. If not, please read Getting started with Elastic Bamboo.
- **Amazon EC2 API Tools** — you must install the EC2 API tools on your local machine, otherwise you will not be able to start and access your AMI instance. Note: you need Java Runtime Environment to run these tools. You can install the EC2 API tools by executing the following commands:

```bash
wget http://s3.amazonaws.com/ec2-downloads/ec2-api-tools.zip
unzip ec2-api-tools.zip
```

- **Environment Variables** — you must set up the following environment variables on your local machine before creating a custom elastic image:
  - `EC2_HOME` — set this to the path to the installed EC2 API Tools
  - `EC2_CERT` — set this to the path to the certificate assigned to EC2 account
  - `EC2_PRIVATE_KEY` — set this to the path to the private key assigned to your AWS account

- **Registered Key Pair** — you need a registered EC2 key pair, which consists of a private key file and certificate file, to use the EC2 API tools with your AMI instance. If you have previously generated and registered an EC2 key pair (e.g. to use the EC2 API tools), you can re-use it. If you need to generate a new key pair, you can use the following command to do so:

```bash
ec2-add-keypair <key_pair_name>
```

The content of the private key will be displayed in the command-line output on your console. Save this content in a file, starting with the line:

```
--BEGIN RSA PRIVATE KEY--
```

and ending with the line:

```
--END RSA PRIVATE KEY--
```

This private key file will be used to access your AMI instance. Set up the appropriate permissions on the private key file by executing the following command:

```bash
chmod 600 <private_key_file>
```

---

### 2. Selecting an existing AMI

We strongly recommend that you select an existing Linux/UNIX AMI to customize, rather than starting with a blank AMI. When choosing an AMI, decide whether you want to launch **32-bit** or **64-bit** instances from your custom elastic image and select an existing AMI matching your choice.

We recommend the following existing Linux/UNIX AMIs for customization (in order of preference):
Atlassian's AMIs (and hence, their IDs) may change with each release of Bamboo, including both major and minor releases. To quickly access Atlassian's AMI IDs for your currently-running version of Bamboo, open that Bamboo site in a web browser and access its 'Image Configurations' page (see Managing your Elastic Image Configurations for more information). The AMI IDs of Atlassian's AMIs are labeled with "(stock image)".

If you want to find out the AMI IDs for a version of Bamboo you don't have running or you're starting an image from scratch and you need the image baseline:

2. On the resulting directory page, click the link that represents the version of Bamboo you are currently running. For example, if you are running Bamboo 5.9.7, click on the 5.9.7 link. Another directory page opens, listing a .pom and some additional checksum files.
   - Do not click on a version number link that contains 'mX', 'rcX' or 'betaX' (where 'X' is a number), since these relate to publicly available developmental releases of Bamboo.
3. Open the atlassian-bamboo-x.x.x.pom file (where x.x.x is your version of Bamboo). The image version/baseline is stored in the elastic-image.version tag. For example, this value is "4.2" for Bamboo version 5.9.4.
5. Click on the image version/baseline you found in the elastic-image.version tag.

On the resulting directory page, the file with ami extension contains all stock image AMI IDs.

### 3. Starting an instance

After you have selected an existing AMI to customize, the next step is to start an instance of the AMI.

#### 3.1 Starting an instance of Atlassian's default AMI

If you chose to customize Atlassian's default AMI, you will have to start the instance from the admin section of Bamboo. See Starting an elastic instance.

Note that Atlassian's default AMI cannot be started using the command line ec2 tools. This is because, on start up, the Bamboo agent on Atlassian's AMI checks to see if it was started from a Bamboo server, and immediately shuts itself down if it was not.

Once started, see Accessing an elastic instance for details on how to access the running instance.

#### 3.2 Starting an instance from the command line

Use the `ec2-run-instances` command to start your instance, as follows:

```
ec2-run-instances <image_name> -k <key_pair_name>
```

where `<image_name>` is the name of the AMI selected in the previous step and `<key_pair_name>` is the name of the registered key pair generated in '1. Requirements'. The public certificate of this key will be injected into your instance.

For example, if you wanted to start an instance of image ami-e55bbd8c using key pair my-keypair, you would run the following command:

```
ec2-run-instances ami-e55bbd8c -k my-keypair
```

This command would produce the following command-line output:

```
INSTANCE   i-25b86743   ami-e55bbd8c   running   my-keypair
```

`i-25b86743` is the name of the new instance in the above example. You should note down the name of your new instance, as you will
need that to access your instance in the next step.

Don’t forget to shut down unused instances
Please note that once you start an instance, you will be billed by Amazon for instance uptime. If you decide to abandon the setup of a custom elastic image after this step, please ensure that you shut down your instance via the AWS console.

3.3 Starting an instance from Bamboo

You can also start a fresh, uncustomized image from Bamboo and begin customization. The drawback of this approach is that you have only 40 minutes before Bamboo shuts down your instance. The advantage is that you can customize the agent in a single step (as opposed to having to customize/create image/start from Bamboo/save image again).

4. Accessing your instance

If you started the instance from Bamboo, see Accessing an elastic instance for details on how to access the running instance.

Once your instance is running, you will need to obtain the address of the instance so you can access it. To do this, use the following command:

```
ec2-describe-instances <instance_name>
```

For example, if you wanted to find the address of instance i-25b86743, you would enter:

```
ec2-describe-instances i-25b86743
```

This command would produce the following command-line output similar to this:

```
RESERVATION r-790f7210 121852097033 default
INSTANCE i-25b86743 ami-e55bbd8c
ee2-174-129-94-241.compute-1.amazonaws.com
domU-12-31-39-04-38-87.compute-1.internal running elasticbamboo 0
m1.small
2009-06-24T12:36:20+0000 us-east-1c aki-a71cf9ce ari-a51cf9cc
monitoring-disabled
```

The address of the instance in the above example is ec2-174-129-94-241.compute-1.amazonaws.com

You can then use this address to access the instance via SSH. See Accessing an elastic instance for instructions. If you are using the example command text from that document, you will need to adjust it as follows:

- replace `/opt/bamboo/home/xml-data/configuration/elasticbamboo.pk` in the example command text with the private key file you generated in 1. Requirements.
- replace `ec2-68-111-185-197.compute-1.amazonaws.com` in the example command text with the address of your instance.

5. Customizing your instance

Now that you have a running instance, customization steps heavily depend on the operating system you’re using. We’ve prepared separate pages with Linux-specific instructions and Windows-specific instructions.

6. Creating an image of your customized instance

The process of creating a new image varies depending whether you based your image on an instance-store or EBS-root image. You can check your image type via AWS console or using `ec2-describe-images`.

Creating an image from EBS-root instances

See here for instructions: Amazon Tutorial

Creating an image from instance-store (S3) instances

The final step is to create an image from your customized instance. To do this, you will require the following information:

- Amazon Account Number
- Access Key ID
• Secret Access Key
• Amazon S3 bucket name that will be used to store image (if you don’t have access to Amazon S3, you can sign up on this page.)

1. Transfer Amazon private key file and certificate to your instance
   Transfer the key files to your instance by running these commands on your local machine:

   ```
   scp -i <private_key_file> $EC2_PRIVATE_KEY
   root@<instance_address>:/mnt
   scp -i <private_key_file> $EC2_CERT root@<instance_address>:/mnt
   ```

   where `<private_key_file>` is the private key file from your local machine created in step ‘Registered Key Pair’ of 1. Requirements and the `<instance_address>` is the address of your instance from ‘4. Accessing your Instance’.

2. Set up EC2_HOME and JAVA_HOME environment variables
   Set up these environment variables by running the following commands on your instance:

   ```
   export EC2_HOME=<location of your EC2 tools installation>
   export EC2_PRIVATE_KEY=/mnt/<ec2_private_key_file>
   export EC2_CERT=/mnt/<ec2_certificate_file>
   export JAVA_HOME=<path to JRE used to start the agent>
   ```

3. You can create an image of your customized instance by using the ec2-bundle-vol command, as follows:

   ```
   ec2-bundle-vol -c $EC2_CERT -k $EC2_PRIVATE_KEY -u <amazon_account_number> -p <elastic_image_name> --batch --debug
   ```

   where `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. ‘CustomImage1’)

4. Once the image is created, you need to upload it to Amazon S3 by running the command below:

   ```
   ec2-upload-bundle -b <s3_bucket_name> -m /tmp/<elastic_image_name>.manifest.xml -a <access_key_id> -s <secret_access_key> --retry --debug
   ```

   where `<s3_bucket_name>`, `<access_key_id>` and `<secret_access_key>` are the Amazon S3 bucket name, Access Key ID and Secret Access Key described previously, and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. ‘CustomImage1’).

   You will then need to register your image with Amazon EC2 by using the ec2-register command:

   ```
   ec2-register <s3_bucket_name>/<elastic_image_name>.manifest.xml
   ```

   where `<s3_bucket_name>` is the Amazon S3 bucket name described previously and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. ‘CustomImage1’). The output of this command will show the AMI ID of your custom image.

7. Next steps

   Now that you have created a custom elastic image, there are two more steps that you will need to complete before you can use it.

   First, you will need to associate your custom elastic image with your Bamboo installation by creating an Elastic Image Configuration. Please note the AMI ID of your new custom image and read Managing your Elastic Image Configurations for further instructions.

   Secondly, you will need to configure the capabilities of the elastic agents that will run on instances started from your image. This is done by adding the appropriate builder, JDK, Perforce and custom capabilities to your elastic image configuration, so that it reflects what
your custom elastic image actually can do. For example, if you have created a custom elastic image with JDK 1.6 and Maven 2 installed, you will need to add capabilities for JDK 1.6 and Maven 2 to the elastic image configuration. Read Configuring Elastic Agent Capabilities for further instructions.

8. Need more help?

If you need more help, there are a number of resources that you can take advantage of:

- AWS Support Center — if you are having problems with any of your Amazon services, not specifically related to Bamboo, you can obtain basic support from the AWS Support Center. Note, you will need to sign up for Premium Support to get access to web/phone support.
- AWS Resource Center — the AWS Resource Center has links to online documentation, code samples and tools for AWS services.
- Bamboo Developer Forums — please feel free to discuss any useful tips or issues regarding this process in the Bamboo Developer Forums.

Creating a custom elastic image v6.0

An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer's boot hard drive and elastic instances would be the software that runs on this operation system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an AMI ID. You can associate multiple elastic images with a Bamboo server. One default shared image is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

At a high level, the process for creating a custom elastic image consists of taking one of the existing Amazon Machine Images (AMIs) available on Amazon EC2, starting an instance of the AMI, customizing the instance and then creating an image from the customized instance. This image can then be used as an elastic image in your Bamboo installation.

Instead of creating a custom image (Linux/UNIX only) consider:

- Using the "Instance setup script" feature to run commands (executed as the root user) before the agent is started. This field is available for every image from the Administration > Image Configurations page. Click the "Edit" link under Operations for the image you want to use.
- Customizing an existing Bamboo image by using Amazon's Elastic Block Store (EBS), as described in Configuring elastic instances to use the EBS.

The options above are much simpler than creating a new custom image. If you are having problems, please don't hesitate to contact us for further help.

Before you begin:

- This is not a trivial procedure and chances are you don't need it.
- Please note, Atlassian does not support custom elastic images. Consider customizing the elastic agents started from your stock images instead.
- A number of the EC2 commands in the steps below can be completed using the AWS console rather than command line tools (e.g. registering an image). You should use the method you feel most comfortable with.

On this page:
1. Requirements
2. Selecting an existing AMI
3. Starting an instance
4. Accessing your instance
5. Customizing your instance
6. Creating an image of your customized instance
7. Next steps
8. Need more help?

1. Requirements
First ensure that you have set up the following:

- **Amazon Web Services (AWS) account with EC2** — if you are already using Elastic Bamboo, you should already have an AWS account with EC2 set up. If not, please read Getting started with Elastic Bamboo.
- **Amazon EC2 API Tools** — you must install the EC2 API tools on your local machine, otherwise you will not be able to start and access your AMI instance. Note: you need Java Runtime Environment to run these tools. You can install the EC2 API tools by executing the following commands:
  
  ```bash
  wget http://s3.amazonaws.com/ec2-downloads/ec2-api-tools.zip
  unzip ec2-api-tools.zip
  ```

- **Environment Variables** — you must set up the following environment variables on your local machine before creating a custom elastic image:
  - `EC2_HOME` — set this to the path to the installed EC2 API Tools
  - `EC2_CERT` — set this to the path to the certificate assigned to EC2 account
  - `EC2_PRIVATE_KEY` — set this to the path to the private key assigned to your AWS account

- **Registered Key Pair** — you need a registered EC2 key pair, which consists of a private key file and certificate file, to use the EC2 API tools with your AMI instance. If you have previously generated and registered an EC2 key pair (e.g. to use the EC2 API tools), you can re-use it. If you need to generate a new key pair, you can use the following command to do so:
  
  ```bash
  ec2-add-keypair <key_pair_name>
  ```

The content of the private key will be displayed in the command-line output on your console. Save this content in a file, starting with the line:

```
--BEGIN RSA PRIVATE KEY--
```

and ending with the line:

```
--END RSA PRIVATE KEY--
```

This private key file will be used to access your AMI instance. Set up the appropriate permissions on the private key file by executing the following command:

```bash
chmod 600 <private_key_file>
```

## 2. Selecting an existing AMI

We strongly recommend that you select an existing Linux/UNIX AMI to customize, rather than starting with a blank AMI. When choosing an AMI, decide whether you want to launch **32-bit** or **64-bit** instances from your custom elastic image and select an existing AMI matching your choice.

We recommend the following existing Linux/UNIX AMIs for customization (in order of preference):

<table>
<thead>
<tr>
<th>Source</th>
<th>Description</th>
<th>AMI list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Atlassian</td>
<td>One of the <strong>Stock images</strong> provided by Atlassian. It is an Amazon image, for either Linux or Windows, updated and prepared for Bamboo, i.e. you will not have to install any Bamboo prerequisites.</td>
<td>Available on your Bamboo instance under Administration/Image Configurations</td>
</tr>
<tr>
<td>Amazon</td>
<td>CentOS-based image provided by Amazon. It does not have any Bamboo prerequisites installed. Typically, you will be better off using the Atlassian AMI.</td>
<td>Amazon's site</td>
</tr>
<tr>
<td>Canonical(Ubuntu)</td>
<td>An official Ubuntu image provided by Canonical (the company behind the Ubuntu Linux project). It does not have any Bamboo prerequisites installed.</td>
<td>Canonical's site</td>
</tr>
</tbody>
</table>

Atlassian's AMIs (and hence, their IDs) may change with each release of Bamboo, including both major and minor releases. To quickly access Atlassian's AMI IDs for your currently-running version of Bamboo, open that Bamboo site in a web browser and access its 'Image Configurations' page (see Managing your Elastic Image Configurations for more information). The AMI IDs of Atlassian's AMIs are labeled with "(stock image)".

If you want to find out the AMI IDs for a version of Bamboo you don't have running or you're starting an image from scratch and you need the image baseline:

2. On the resulting directory page, click the link that represents the version of Bamboo you are currently running. For example, if you are running Bamboo 5.9.7, click on the 5.9.7 link. Another directory page opens, listing a .pom and some additional
checksum files.

⚠️ Do not click on a version number link that contains 'mX', 'rcX' or 'betaX' (where 'X' is a number), since these relate to publicly available developmental releases of Bamboo.

3. Open the atlassian-bamboo-x.x.x.pom file (where x.x.x) is your version of Bamboo). The image version/baseline is stored in the elastic-image.version tag. For example, this value is "4.2" for Bamboo version 5.9.4.

5. Click on the image version/baseline you found in the elastic-image.version tag.

On the resulting directory page, the file with .pom extension contains all stock image AMI IDs.

3. Starting an instance

After you have selected an existing AMI to customize, the next step is to start an instance of the AMI.

3.1 Starting an instance of Atlassian's default AMI

If you chose to customize Atlassian's default AMI, you will have to start the instance from the admin section of Bamboo. See Starting an elastic instance.

Note that Atlassian's default AMI cannot be started using the command line ec2 tools. This is because, on start up, the Bamboo agent on Atlassian's AMI checks to see if it was started from a Bamboo server, and immediately shuts itself down if it was not.

Once started, see Accessing an elastic instance for details on how to access the running instance.

3.2 Starting an instance from the command line

Use the ec2-run-instances command to start your instance, as follows:

```
ec2-run-instances <image_name> -k <key_pair_name>
```

where `<image_name>` is the name of the AMI selected in the previous step and `<key_pair_name>` is the name of the registered key pair generated in '1. Requirements'. The public certificate of this key will be injected into your instance.

For example, if you wanted to start an instance of image ami-e55bbd8c using key pair my-keypair, you would run the following command:

```
ec2-run-instances ami-e55bbd8c -k my-keypair
```

This command would produce the following command-line output:

```
INSTANCE        i-25b86743   ami-e55bbd8c     running   my-keypair
```

`i-25b86743` is the name of the new instance in the above example. You should note down the name of your new instance, as you will need that to access your instance in the next step.

Don't forget to shut down unused instances

Please note that once you start an instance, you will be billed by Amazon for instance uptime. If you decide to abandon the setup of a custom elastic image after this step, please ensure that you shut down your instance via the AWS console.

3.3 Starting an instance from Bamboo

You can also start a fresh, uncustomized image from Bamboo and begin customization. The drawback of this approach is that you have only 40 minutes before Bamboo shuts down your instance. The advantage is that you can customize the agent in a single step (as opposed to having to customize/create image/start from Bamboo/save image again).

4. Accessing your instance

If you started the instance from Bamboo, see Accessing an elastic instance for details on how to access the running instance.

Once your instance is running, you will need to obtain the address of the instance so you can access it. To do this, use the following command:
```
ec2-describe-instances <instance_name>
```

For example, if you wanted to find the address of instance i-25b86743, you would enter:
```
ec2-describe-instances i-25b86743
```

This command would produce the following command-line output similar to this:
```
RESERVATION r-790f7210 121852097033 default
INSTANCE i-25b86743 ami-e55bbd8c
domU-12-31-39-04-38-87.compute-1.internal running elasticbamboo 0
m1.small
2009-06-24T12:36:20+0000 us-east-1c aki-a71cf9ce ari-a51cf9cc
monitoring-disabled
```

The address of the instance in the above example is `ec2-174-129-94-241.compute-1.amazonaws.com`

You can then use this address to access the instance via SSH. See Accessing an elastic instance for instructions. If you are using the example command text from that document, you will need to adjust it as follows:

- replace `/opt/bamboo/home/xml-data/configuration/elasticbamboo.pk` in the example command text with the private key file you generated in '1. Requirements'.
- replace `ec2-68-111-185-197.compute-1.amazonaws.com` in the example command text with the address of your instance.

5. Customizing your instance

Now that you have a running instance, customization steps heavily depend on the operating system you’re using. We’ve prepared separate pages with Linux-specific instructions and Windows-specific instructions.

6. Creating an image of your customized instance

The process of creating a new image varies depending whether you based your image on an instance-store or EBS-root image. You can check your image type via AWS console or using `ec2-describe-images`.

Creating an image from EBS-root instances

See here for instructions: Amazon Tutorial

Creating an image from instance-store (S3) instances

The final step is to create an image from your customized instance. To do this, you will require the following information:

- Amazon Account Number
- Access Key ID
- Secret Access Key
- Amazon S3 bucket name that will be used to store image (if you don’t have access to Amazon S3, you can sign up on this page)

1. Transfer Amazon private key file and certificate to your instance

Transfer the key files to your instance by running these commands on your local machine:

```
scp -i <private_key_file> $EC2_PRIVATE_KEY root@<instance_address>:/mnt
scp -i <private_key_file> $EC2_CERT root@<instance_address>:/mnt
```

where `<private_key_file>` is the private key file from your local machine created in step ‘Registered Key Pair’ of 1. Requirements and the `<instance_address>` is the address of your instance from ‘4. Accessing your Instance’.

2. Set up `EC2_HOME` and `JAVA_HOME` environment variables

Set up these environment variables by running the following commands on your instance:
export EC2_HOME=<location of your EC2 tools installation>
export EC2_PRIVATE_KEY=/mnt/<ec2_private_key_file>
export EC2_CERT=/mnt/<ec2_certificate_file>
export JAVA_HOME=<path to JRE used to start the agent>

3. You can create an image of your customized instance by using the `ec2-bundle-vol` command, as follows:

```
ec2-bundle-vol -c $EC2_CERT -k $EC2_PRIVATE_KEY -u
<amazon_account_number> -p <elastic_image_name> --batch --debug
```

where `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1')

4. Once the image is created, you need to upload it to Amazon S3 by running the command below:

```
ec2-upload-bundle -b <s3_bucket_name> -m
/tmp/<elastic_image_name>.manifest.xml -a <access_key_id> -s
<secret_access_key> --retry --debug
```

where `<s3_bucket_name>`, `<access_key_id>` and `<secret_access_key>` are the Amazon S3 bucket name, Access Key ID and Secret Access Key described previously, and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1').

You will then need to register your image with Amazon EC2 by using the `ec2-register` command:

```
ec2-register <s3_bucket_name>/<elastic_image_name>.manifest.xml
```

where `<s3_bucket_name>` is the Amazon S3 bucket name described previously and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1'). The output of this command will show the AMI ID of your custom image.

7. Next steps

Now that you have created a custom elastic image, there are **two more steps** that you will need to complete before you can use it.

First, you will need to **associate your custom elastic image with your Bamboo installation** by creating an Elastic Image Configuration. Please note the AMI ID of your new custom image and read *Managing your Elastic Image Configurations* for further instructions.

Secondly, you will need to **configure the capabilities of the elastic agents** that will run on instances started from your image. This is done by adding the appropriate builder, JDK, Perforce and custom capabilities to your elastic image configuration, so that it reflects what your custom elastic image actually can do. For example, if you have created a custom elastic image with JDK 1.6 and Maven 2 installed, you will need to add capabilities for JDK 1.6 and Maven 2 to the elastic image configuration. Read *Configuring Elastic Agent Capabilities* for further instructions.

8. Need more help?

If you need **more help**, there are a number of resources that you can take advantage of:

- **AWS Support Center** — if you are having problems with any of your Amazon services, not specifically related to Bamboo, you can obtain basic support from the AWS Support Center. Note, you will need to sign up for Premium Support to get access to web/phone support.
- **AWS Resource Center** — the AWS Resource Center has links to online documentation, code samples and tools for AWS services.
- **Bamboo Developer Forums** — please feel free to discuss any useful tips or issues regarding this process in the Bamboo Developer Forums.
Creating a custom elastic image v6.1

Atlassian doesn't provide support for customized images. Bamboo provides flexibility to use customized machine images, but it's impossible for us to support all individual configurations.

Use Bamboo stock images as the base for all image customizations to ensure a minimal level of consistency of your Elastic Bamboo setup.

An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer's boot hard drive and elastic instances would be the software that runs on this operation system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an AMI ID.

You can associate multiple elastic images with a Bamboo server. One default shared image is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

At a high level, the process for creating a custom elastic image consists of taking one of the existing Amazon Machine Images (AMIs) available on Amazon EC2, starting an instance of the AMI, customizing the instance and then creating an image from the customized instance. This image can then be used as an elastic image in your Bamboo installation.

Instead of creating a custom image (Linux/UNIX only) consider:

- Using the "Instance setup script" feature to run commands (executed as the root user) before the agent is started. This field is available for every image from the Administration > Image Configurations page. Click the "Edit" link under Operations for the image you want to use.
- Customizing an existing Bamboo image by using Amazon's Elastic Block Store (EBS), as described in Configuring elastic instances to use the EBS.

The options above are much simpler than creating a new custom image. If you are having problems, please don't hesitate to contact us for further help.

Before you begin:

- This is not a trivial procedure and chances are you don't need it.
- Please note, Atlassian does not support custom elastic images. Consider customizing the elastic agents started from your stock images instead.
- A number of the EC2 commands in the steps below can be completed using the AWS console rather than command line tools (e.g. registering an image). You should use the method you feel most comfortable with.

On this page:
1. Requirements
2. Selecting an existing AMI
3. Starting an instance
4. Accessing your instance
5. Customizing your instance
6. Creating an image of your customized instance
7. Next steps
8. Need more help?

1. Requirements

First ensure that you have set up the following:

- Amazon Web Services (AWS) account with EC2 — if you are already using Elastic Bamboo, you should already have an AWS account with EC2 set up. If not, please read Getting started with Elastic Bamboo.
- Amazon EC2 API Tools — you must install the EC2 API tools on your local machine, otherwise you will not be able to start and access your AMI instance. Note: you need Java Runtime Environment to run these tools. You can install the EC2 API tools by executing the following commands:

```
wget http://s3.amazonaws.com/ec2-downloads/ec2-api-tools.zip
unzip ec2-api-tools.zip
```

- Environment Variables — you must set up the following environment variables on your local machine before creating a custom elastic image:
  - EC2_HOME — set this to the path to the installed EC2 API Tools
  - EC2_CERT — set this to the path to the certificate assigned to EC2 account
  - EC2_PRIVATE_KEY — set this to the path to the private key assigned to your AWS account

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
1. **Registered Key Pair**— you need a registered EC2 key pair, which consists of a private key file and certificate file, to use the EC2 API tools with your AMI instance. If you have previously generated and registered an EC2 key pair (e.g. to use the EC2 API tools), you can re-use it. If you need to generate a new key pair, you can use the following command to do so:

   ```
   ec2-add-keypair <key_pair_name>
   ```

   The content of the private key will be displayed in the command-line output on your console. Save this content in a file, starting with the line:
   ```
   "--BEGIN RSA PRIVATE KEY--"
   ```

   and ending with the line:
   ```
   "--END RSA PRIVATE KEY--"
   ```

   This private key file will be used to access your AMI instance. Set up the appropriate permissions on the private key file by executing the following command:

   ```
   chmod 600 <private_key_file>
   ```

2. **Selecting an existing AMI**

   We strongly recommend that you select an existing Linux/UNIX AMI to customize, rather than starting with a blank AMI. When choosing an AMI, decide whether you want to launch **32-bit** or **64-bit** instances from your custom elastic image and select an existing AMI matching your choice.

   We recommend the following existing Linux/UNIX AMIs for customization (in order of preference):

<table>
<thead>
<tr>
<th>Source</th>
<th>Description</th>
<th>AMI list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Atlassian</td>
<td>One of the <strong>Stock images</strong> provided by Atlassian. It is an Amazon image, for either Linux or Windows, updated and prepared for Bamboo, i.e. you will not have to install any Bamboo prerequisites.</td>
<td>Available on your Bamboo instance under Administration/Image Configurations</td>
</tr>
<tr>
<td>Amazon</td>
<td>CentOS-based image provided by Amazon. It does not have any Bamboo prerequisites installed. Typically, you will be better off using the Atlassian AMI.</td>
<td>Amazon's site</td>
</tr>
<tr>
<td>Canonical(Ubuntu)</td>
<td>An official Ubuntu image provided by Canonical (the company behind the Ubuntu Linux project). It does not have any Bamboo prerequisites installed.</td>
<td>Canonical's site</td>
</tr>
</tbody>
</table>

   Atlassian's AMIs (and hence, their IDs) may change with each release of Bamboo, including both major and minor releases. To quickly access Atlassian's AMI IDs for your currently-running version of Bamboo, open that Bamboo site in a web browser and access its 'Image Configurations' page (see managing your Elastic Image Configurations for more information). The AMI IDs of Atlassian's AMIs are labeled with "(stock image)".

   If you want to find out the AMI IDs for a version of Bamboo you don't have running or you're starting an image from scratch and you need the image baseline:

   2. On the resulting directory page, click the link that represents the version of Bamboo you are currently running. For example, if you are running Bamboo 5.9.7, click on the 5.9.7 link. Another directory page opens, listing a .pom and some additional checksum files.

   ![Warning]

   Do not click on a version number link that contains 'mX', 'rcX' or 'betaX' (where 'X' is a number), since these relate to publicly available developmental releases of Bamboo.

   3. Open the atlassian-bamboo-x.x.x.pom file (where x.x.x is your version of Bamboo). The image version/baseline is stored in the `elastic-image.version` tag. For example, this value is "4.2" for Bamboo version 5.9.4.
   5. Click on the image version/baseline you found in the `elastic-image.version` tag.

   ![Warning]

   On the resulting directory page, the file with .ami extension contains all stock image AMI IDs.

3. **Starting an instance**

   After you have selected an existing AMI to customize, the next step is to start an instance of the AMI.

   3.1 Starting an instance of Atlassian's default AMI

   If you chose to customize Atlassian's default AMI, you will have to start the instance from the admin section of Bamboo. See Starting an elastic instance.
Note that Atlassian’s default AMI cannot be started using the command line `ec2` tools. This is because, on start up, the Bamboo agent on Atlassian’s AMI checks to see if it was started from a Bamboo server, and immediately shuts itself down if it was not.

Once started, see Accessing an elastic instance for details on how to access the running instance.

### 3.2 Starting an instance from the command line

Use the `ec2-run-instances` command to start your instance, as follows:

```
ec2-run-instances <image_name> -k <key_pair_name>
```

where `<image_name>` is the name of the AMI selected in the previous step and `<key_pair_name>` is the name of the registered key pair generated in `1. Requirements`. The public certificate of this key will be injected into your instance.

For example, if you wanted to start an instance of image `ami-e55bbd8c` using key pair `my-keypair`, you would run the following command:

```
ec2-run-instances ami-e55bbd8c -k my-keypair
```

This command would produce the following command-line output:

```
INSTANCE        i-25b86743   ami-e55bbd8c     running   my-keypair
```

`i-25b86743` is the name of the new instance in the above example. You should note down the name of your new instance, as you will need that to access your instance in the next step.

### 3.3 Starting an instance from Bamboo

You can also start a fresh, uncustomized image from Bamboo and begin customization. The drawback of this approach is that you have only 40 minutes before Bamboo shuts down your instance. The advantage is that you can customize the agent in a single step (as opposed to having to customize/create image/start from Bamboo/save image again).

### 4. Accessing your instance

Once your instance is running, you will need to obtain the address of the instance so you can access it. To do this, use the following command:

```
ec2-describe-instances <instance_name>
```

For example, if you wanted to find the address of instance `i-25b86743`, you would enter:

```
ec2-describe-instances i-25b86743
```

This command would produce the following command-line output similar to this:

```
INSTANCES
```

Don’t forget to shut down unused instances

Please note that once you start an instance, you will be billed by Amazon for instance uptime. If you decide to abandon the setup of a custom elastic image after this step, please ensure that you shut down your instance via the AWS console.

If you started the instance from Bamboo, see Accessing an elastic instance for details on how to access the running instance.

Once your instance is running, you will need to obtain the address of the instance so you can access it. To do this, use the following command:

```
ec2-describe-instances <instance_name>
```

For example, if you wanted to find the address of instance `i-25b86743`, you would enter:

```
ec2-describe-instances i-25b86743
```

This command would produce the following command-line output similar to this:
RESERVATION r-790f7210 121852097033 default
INSTANCES i-25b86743 ami-e55bbd8c
  ec2-174-129-94-241.compute-1.amazonaws.com
domU-12-31-39-04-38-87.compute-1.internal running elasticbamboo 0
  m1.small
  2009-06-24T12:36:20+0000 us-east-1c aki-a71cf9ce ari-a51cf9cc
  monitoring-disabled

The address of the instance in the above example is ec2-174-129-94-241.compute-1.amazonaws.com

You can then use this address to access the instance via SSH. See Accessing an elastic instance for instructions. If you are using the example command text from that document, you will need to adjust it as follows:

- replace /opt/bamboo/home/xml-data/configuration/elasticbamboo.pk in the example command text with the private key file you generated in 1. Requirements.
- replace ec2-68-111-185-197.compute-1.amazonaws.com in the example command text with the address of your instance.

5. Customizing your instance

Now that you have a running instance, customization steps heavily depend on the operating system you're using. We've prepared separate pages with Linux-specific instructions and Windows-specific instructions.

6. Creating an image of your customized instance

The process of creating a new image varies depending whether you based your image on an instance-store or EBS-root image. You can check your image type via AWS console or using ec2-describe-images.

Creating an image from EBS-root instances

See here for instructions: Amazon Tutorial

Creating an image from instance-store (S3) instances

The final step is to create an image from your customized instance. To do this, you will require the following information:

- Amazon Account Number
- Access Key ID
- Secret Access Key
- Amazon S3 bucket name that will be used to store image (if you don't have access to Amazon S3, you can sign up on this page.)

1. Transfer Amazon private key file and certificate to your instance

Transfer the key files to your instance by running these commands on your local machine:

```bash
scp -i <private_key_file> $EC2_PRIVATE_KEY root@<instance_address>:/mnt
scp -i <private_key_file> $EC2_CERT root@<instance_address>:/mnt
```

where <private_key_file> is the private key file from your local machine created in step 'Registered Key Pair' of 1. Requirements and the <instance_address> is the address of your instance from '4. Accessing your Instance'.

2. Set up EC2_HOME and JAVA_HOME environment variables

Set up these environment variables by running the following commands on your instance:

```bash
export EC2_HOME=<location of your EC2 tools installation>
export EC2_PRIVATE_KEY=/mnt/<ec2_private_key_file>
export EC2_CERT=/mnt/<ec2_certificate_file>
export JAVA_HOME=<path to JRE used to start the agent>
```

3. You can create an image of your customized instance by using the ec2-bundle-vol command, as follows:
3. Creating a custom elastic image v6.2

Atlassian doesn't provide support for customized images. Bamboo provides flexibility to use customized machine images, but it's impossible for us to support all individual configurations. Use Bamboo stock images as the base for all image customizations to ensure a minimal level of consistency of your Elastic Bamboo setup.
An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer's boot hard drive and elastic instances would be the software that runs on this operation system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an AMI ID.

You can associate multiple elastic images with a Bamboo server. One default shared image is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

At a high level, the process for creating a custom elastic image consists of taking one of the existing Amazon Machine Images (AMIs) available on Amazon EC2, starting an instance of the AMI, customizing the instance and then creating an image from the customized instance. This image can then be used as an elastic image in your Bamboo installation.

Instead of creating a custom image (Linux/UNIX only) consider:

- Using the "Instance setup script" feature to run commands (executed as the root user) before the agent is started. This field is available for every image from the Administration > Image Configurations page. Click the "Edit" link under Operations for the image you want to use.
- Customizing an existing Bamboo image by using Amazon's Elastic Block Store (EBS), as described in Configuring elastic instances to use the EBS.

The options above are much simpler than creating a new custom image. If you are having problems, please don't hesitate to contact us for further help.

Before you begin:

- This is not a trivial procedure and chances are you don't need it.
- Please note, Atlassian does not support custom elastic images. Consider customizing the elastic agents started from your stock images instead.
- A number of the EC2 commands in the steps below can be completed using the AWS console rather than command line tools (e.g. registering an image). You should use the method you feel most comfortable with.

### On this page:
1. Requirements
2. Selecting an existing AMI
3. Starting an instance
4. Accessing your instance
5. Customizing your instance
6. Creating an image of your customized instance
7. Next steps
8. Need more help?

#### 1. Requirements

First ensure that you have set up the following:

- **Amazon Web Services (AWS) account with EC2** — if you are already using Elastic Bamboo, you should already have an AWS account with EC2 set up. If not, please read [Getting started with Elastic Bamboo](https://confluence.atlassian.com/ee1575229-getting-started-with-elastic-bamboo.html).
- **Amazon EC2 API Tools** — you must install the EC2 API tools on your local machine, otherwise you will not be able to start and access your AMI instance. Note: you need Java Runtime Environment to run these tools. You can install the EC2 API tools by executing the following commands:

```bash
wget http://s3.amazonaws.com/ec2-downloads/ec2-api-tools.zip
unzip ec2-api-tools.zip
```

- **Environment Variables** — you must set up the following environment variables on your local machine before creating a custom elastic image:
  - `EC2_HOME` — set this to the path to the installed EC2 API Tools
  - `EC2_CERT` — set this to the path to the certificate assigned to EC2 account
  - `EC2_PRIVATE_KEY` — set this to the path to the private key assigned to your AWS account

- **Registered Key Pair** — you need a registered EC2 key pair, which consists of a private key file and certificate file, to use the EC2 API tools with your AMI instance. If you have previously generated and registered an EC2 key pair (e.g. to use the EC2 API tools), you can re-use it. If you need to generate a new key pair, you can use the following command to do so:

```bash
ec2-add-keypair <key_pair_name>
```

The content of the private key will be displayed in the command-line output on your console. Save this content in a file, starting with the line:

```
--BEGIN RSA PRIVATE KEY--
```

and ending with the line:

```
--END RSA PRIVATE KEY--
```
This private key file will be used to access your AMI instance. Set up the appropriate permissions on the private key file by executing the following command:

```
chmod 600 <private_key_file>
```

### 2. Selecting an existing AMI

We strongly recommend that you select an existing Linux/UNIX AMI to customize, rather than starting with a blank AMI. When choosing an AMI, decide whether you want to launch **32-bit** or **64-bit** instances from your custom elastic image and select an existing AMI matching your choice.

We recommend the following existing Linux/UNIX AMIs for customization (in order of preference):

<table>
<thead>
<tr>
<th>Source</th>
<th>Description</th>
<th>AMI list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Atlassian</td>
<td>One of the <strong>stock images</strong> provided by Atlassian. It is an Amazon image, for either Linux or Windows, updated and prepared for Bamboo, i.e. you will not have to install any Bamboo prerequisites.</td>
<td>Available on your Bamboo instance under Administration/Image Configurations</td>
</tr>
<tr>
<td>Amazon</td>
<td>CentOS-based image provided by Amazon. It does not have any Bamboo prerequisites installed. Typically, you will be better off using the Atlassian AMI.</td>
<td>Amazon's site</td>
</tr>
<tr>
<td>Canonical(Ubuntu)</td>
<td>An official Ubuntu image provided by Canonical (the company behind the Ubuntu Linux project). It does not have any Bamboo prerequisites installed.</td>
<td>Canonical's site</td>
</tr>
</tbody>
</table>

Atlassian's AMIs (and hence, their IDs) may change with each release of Bamboo, including both major and minor releases. To quickly access Atlassian's AMI IDs for your currently-running version of Bamboo, open that Bamboo site in a web browser and access its 'Image Configurations' page (see Managing your Elastic Image Configurations for more information). The AMI IDs of Atlassian's AMIs are labeled with "(stock image)".

If you want to find out the AMI IDs for a version of Bamboo you don’t have running or you’re starting an image from scratch and you need the image baseline:

2. On the resulting directory page, click the link that represents the version of Bamboo you are currently running. For example, if you are running Bamboo 5.9.7, click on the 5.9.7 link. Another directory page opens, listing a .pom and some additional checksum files.

   **Caution:** Do not click on a version number link that contains 'mX', 'rcX' or 'betaX' (where 'X' is a number), since these relate to publicly available developmental releases of Bamboo.

3. Open the atlassian-bamboo-x.x.x.pom file (where x.x.x is your version of Bamboo). The image version/baseline is stored in the `elastic-image.version` tag. For example, this value is "4.2" for Bamboo version 5.9.4.
5. Click on the image version/baseline you found in the `elastic-image.version` tag.

   On the resulting directory page, the file with `ami` extension contains all stock image AMI IDs.

### 3. Starting an instance

After you have selected an existing AMI to customize, the next step is to start an instance of the AMI.

#### 3.1 Starting an instance of Atlassian's default AMI

If you chose to customize Atlassian's default AMI, you will have to start the instance from the admin section of Bamboo. See Starting an elastic instance.

Note that Atlassian's default AMI cannot be started using the command line ec2 tools. This is because, on start up, the Bamboo agent on Atlassian's AMI checks to see if it was started from a Bamboo server, and immediately shuts itself down if it was not.

Once started, see Accessing an elastic instance for details on how to access the running instance.

3.2 Starting an instance from the command line

Use the `ec2-run-instances` command to start your instance, as follows:

```
ec2-run-instances <image_name> -k <key_pair_name>
```
where `<image_name>` is the name of the AMI selected in the previous step and `<key_pair_name>` is the name of the registered key pair generated in '1. Requirements'. The public certificate of this key will be injected into your instance.

For example, if you wanted to start an instance of image `ami-e55bbd8c` using key pair `my-keypair`, you would run the following command:

```
ec2-run-instances ami-e55bbd8c -k my-keypair
```

This command would produce the following command-line output:

```
INSTANCE        i-25b86743   ami-e55bbd8c     running   my-keypair
```

`i-25b86743` is the name of the new instance in the above example. You should note down the name of your new instance, as you will need that to **access your instance** in the next step.

Don't forget to shut down unused instances

Please note that once you start an instance, you will be billed by Amazon for instance uptime. If you decide to abandon the setup of a custom elastic image after this step, please ensure that you **shut down your instance** via the AWS console.

3.3 Starting an instance from Bamboo

You can also start a fresh, uncustomized image from Bamboo and begin customization. The drawback of this approach is that you have only 40 minutes before Bamboo shuts down your instance. The advantage is that you can customize the agent in a single step (as opposed to having to customize/create image/start from Bamboo/save image again).

4. Accessing your instance

Once your instance is running, you will need to obtain the address of the instance so you can access it. To do this, use the following command:

```
ec2-describe-instances <instance_name>
```

For example, if you wanted to find the address of instance `i-25b86743`, you would enter:

```
ec2-describe-instances i-25b86743
```

This command would produce the following command-line output similar to this:

```
RESERVATION r-790f7210 121852097033 default
INSTANCE i-25b86743 ami-e55bbd8c
c2e-174-129-94-241.compute-1.amazonaws.com
domU-12-31-39-04-38-87.compute-1.internal running elasticbamboo 0
m1.small
2009-06-24T12:36:20+0000 us-east-1c aki-a71cf9ce ari-a51cf9cc
monitoring-disabled
```

The address of the instance in the above example is `ec2-174-129-94-241.compute-1.amazonaws.com`

You can then use this address to access the instance via SSH. See **Accessing an elastic instance** for instructions. If you are using the example command text from that document, you will need to adjust it as follows:

- replace `/opt/bamboo/home/xml-data/configuration/elasticbamboo.pk` in the example command text with the private key file you generated in '1. Requirements'.
- replace `ec2-68-111-185-197.compute-1.amazonaws.com` in the example command text with the address of your instance.
5. Customizing your instance

Now that you have a running instance, customization steps heavily depend on the operating system you're using. We've prepared separate pages with Linux-specific instructions and Windows-specific instructions.

6. Creating an image of your customized instance

The process of creating a new image varies depending whether you based your image on an instance-store or EBS-root image. You can check your image type via AWS console or using ec2-describe-images.

Creating an image from EBS-root instances

See here for instructions: Amazon Tutorial

Creating an image from instance-store (S3) instances

The final step is to create an image from your customized instance. To do this, you will require the following information:

- Amazon Account Number
- Access Key ID
- Secret Access Key
- Amazon S3 bucket name that will be used to store image (if you don't have access to Amazon S3, you can sign up on this page.)

1. Transfer Amazon private key file and certificate to your instance

Transfer the key files to your instance by running these commands on your local machine:

```
scp -i <private_key_file> $EC2_PRIVATE_KEY root@<instance_address>:~
scp -i <private_key_file> $EC2_CERT root@<instance_address>:~
```

where `<private_key_file>` is the private key file from your local machine created in step 'Registered Key Pair' of 1. Requirements and the `<instance_address>` is the address of your instance from '4. Accessing your Instance'.

2. Set up EC2_HOME and JAVA_HOME environment variables

Set up these environment variables by running the following commands on your instance:

```
export EC2_HOME=<location of your EC2 tools installation>
export EC2_PRIVATE_KEY=/mnt/<ec2_private_key_file>
export EC2_CERT=/mnt/<ec2_certificate_file>
export JAVA_HOME=<path to JRE used to start the agent>
```

3. You can create an image of your customized instance by using the `ec2-bundle-vol` command, as follows:

```
ec2-bundle-vol -c $EC2_CERT -k $EC2_PRIVATE_KEY -u <amazon_account_number> -p <elastic_image_name> --batch --debug
```

where `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1')

4. Once the image is created, you need to upload it to Amazon S3 by running the command below:

```
ec2-upload-bundle -b <s3_bucket_name> -m /tmp/<elastic_image_name>.manifest.xml -a <access_key_id> -s <secret_access_key> --retry --debug
```

where `<s3_bucket_name>`, `<access_key_id>` and `<secret_access_key>` are the Amazon S3 bucket name, Access Key ID and Secret Access Key described previously, and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1').

You will then need to register your image with Amazon EC2 by using the `ec2-register` command:
ec2-register <s3_bucket_name>/<elastic_image_name>.manifest.xml

where <s3_bucket_name> is the Amazon S3 bucket name described previously and <elastic_image_name> is the name that you want to assign to your custom image (e.g. 'CustomImage1'). The output of this command will show the AMI ID of your custom image.

7. Next steps

Now that you have created a custom elastic image, there are two more steps that you will need to complete before you can use it.

First, you will need to associate your custom elastic image with your Bamboo installation by creating an Elastic Image Configuration. Please note the AMI ID of your new custom image and read Managing your Elastic Image Configurations for further instructions.

Secondly, you will need to configure the capabilities of the elastic agents that will run on instances started from your image. This is done by adding the appropriate builder, JDK, Perforce and custom capabilities to your elastic image configuration, so that it reflects what your custom elastic image actually can do. For example, if you have created a custom elastic image with JDK 1.6 and Maven 2 installed, you will need to add capabilities for JDK 1.6 and Maven 2 to the elastic image configuration. Read Configuring Elastic Agent Capabilities for further instructions.

8. Need more help?

If you need more help, there are a number of resources that you can take advantage of:

- AWS Support Center — if you are having problems with any of your Amazon services, not specifically related to Bamboo, you can obtain basic support from the AWS Support Center. Note, you will need to sign up for Premium Support to get access to web/phone support.
- AWS Resource Center — the AWS Resource Center has links to online documentation, code samples and tools for AWS services.
- Bamboo Developer Forums — please feel free to discuss any useful tips or issues regarding this process in the Bamboo Developer Forums.

Upgrading the agent for your custom elastic image

The instructions below are valid if you were using Bamboo 3.4 or newer. If you're upgrading from an earlier version, you should first reinstall the agent installer (see Creating a custom elastic image).

If you customized your instance according to Creating a custom elastic image, your instance will keep itself updated across Bamboo. The synchronization process takes a while and the time required increases as your image gets older. If you notice slow startup, you may want to refresh your image. You can either customize the instance from scratch, as when you created your customized image, or update just the agent data, which is much faster.

To refresh your agent data:

1. Start your instance from Bamboo.
2. Log into your instance.
3. Run /opt/bamboo-elastic-agent/bin/prepareInstanceForSaving.sh.
4. Create an Image of your Customized Instance.

The final step is to create an image from your customized instance. To do this, you will require the following information:

- Amazon Account Number
- Access Key ID
- Secret Access Key
- Amazon S3 bucket name that will be used to store image (if you don't have access to Amazon S3, you can sign up on this page.)

You can create an image of your customized instance by using the ec2-bundle-vol command, as follows:
4. Create your custom image on Amazon EC2

```
/usr/local/bin/ec2-bundle-vol -c $EC2_CERT -k $EC2_PRIVATE_KEY -u <amazon_account_number> -p <elastic_image_name> --batch --debug
```

where `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1')

Once the image is created, you need to upload it to Amazon S3 by running the command below:

```
/usr/local/bin/ec2-upload-bundle -b <s3_bucket_name> -m /tmp/<elastic_image_name>.manifest.xml -a <access_key_id> -s <secret_access_key> --retry --debug
```

where `<s3_bucket_name>`, `<access_key_id>` and `<secret_access_key>` are the Amazon S3 bucket name, Access Key ID and Secret Access Key described previously, and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1')

You will then need to register your image with Amazon EC2 by using the `ec2-register` command:

```
$EC2_HOME/bin/ec2-register
<s3_bucket_name>/<elastic_image_name>.manifest.xml
```

where `<s3_bucket_name>` is the Amazon S3 bucket name described previously and `<elastic_image_name>` is the name that you want to assign to your custom image (e.g. 'CustomImage1')

The output of this command will show the AMI ID of your custom image.

5. Associate the new Custom Image with Bamboo.

Finally, you will need to associate your custom elastic image with your Bamboo installation by creating an Elastic Image Configuration. Please note the AMI ID of your new custom image and read Managing your elastic image configurations for further instructions.

Updating elastic images for Bamboo upgrades

Various updates to default packages and capabilities are made to the default image with each major release of Bamboo.

Therefore, if you are using either a:

- custom elastic image, or
- an elastic image with customized agent capabilities

then to ensure this elastic image acquires these package/capability updates, use the flow chart below to update your elastic image.

⚠️ Use this flowchart only after Bamboo has been upgraded. For each elastic image you wish to update, follow this flow chart from the start.
1. Viewing the list of Bamboo stock images

Bamboo provides a collection of Amazon Machine Images (AMIs) that are ready for use or further customization. Each AMI is identified by its unique ID. For more information about the parameters of the stock images, see Stock images.

Atlassian AMIs and their IDs may change with each minor or major Bamboo release.

- Viewing a list of AMI IDs available for a release
- Troubleshooting

Viewing a list of AMI IDs available for a release

To generate a list of AMI IDs for a Bamboo version:

1. Save the following script as a .sh file:
if [ $# -eq 0 ]; then
    echo "Usage: `basename $0` [5.8.3] (Your Bamboo version)"
    exit 0
fi

BAMBOO_VERSION=$1
echo For Bamboo version: $BAMBOO_VERSION
ELASTIC_VERSION="$(curl -v --silent https://maven.atlassian.com/content/groups/public/com/atlassian/bamboo/atlassian-bamboo/$BAMBOO_VERSION/atlassian-bamboo-$BAMBOO_VERSION.pom 2>&1 | grep <elastic-image.version> | sed -e 's/[^>]*>//g' -e 's/\[/:space:\]/" -e 's/[:space:]]*$/"'"

echo "Elastic bamboo version is $ELASTIC_VERSION"

echo "REMEMBER: Use the image from the appropriate region!"

In the terminal, go to the directory where you saved the file and run it with the following command:

./<name-of-your-file>.sh <your-bamboo-version>

Example

./amis.sh 5.9.3

If you get the "Permission denied" error, you can modify the permissions of the .sh file with the following:

chmod +x <name-of-the-file>.sh

Results

Click the example to see the full script output.

Example

For Bamboo 5.9.3, the results can be the following:
For Bamboo version: 5.9.3

Elastic bamboo version is 4.2

> GET
/content/repositories/atlassian-public/com/atlassian/bamboo/atlassian-bamboo-elastic-image/4.2/atlassian-bamboo-elastic-image-4.2.ami HTTP/1.1

Troubleshooting

If the script above doesn’t work, you can also find the list of Bamboo stock images in the following way:

1. In the following URL:

```
https://maven.atlassian.com/content/repositories/atlassian-public/com/atlassian/bamboo/atlassian-bamboo/$BAMBOO_VERSION/atlassian-bamboo-$BAMBOO_VERSION.pom
```

change $BAMBOO_VERSION to the Bamboo version number for which you want to list the AMIs.

Example

For Bamboo 5.9.3:

```
https://maven.atlassian.com/content/repositories/atlassian-public/com/atlassian/bamboo/atlassian-bamboo/5.9.3/atlassian-bamboo-5.9.3.pom
```

2. Open the URL in a browser.
3. In the atlassian-bamboo-$BAMBOO_VERSION.pom file (where $BAMBOO_VERSION is your version of Bamboo), find the elastic image version for the release. The image version (baseline) is stored as an elastic-image.version property.
Example
For the version 5.9.7 (atlassian-bamboo-5.9.7.pom), the elastic image version was 4.2:

```
<elastic-image.version>4.2</elastic-image.version>
```

4. In the following URL:

```
```

change $ELASTIC_VERSION to the Bamboo elastic version number from Step 3.

Example
For Bamboo elastic version 4.2, which is the baseline for Bamboo 5.9.3:

```
https://maven.atlassian.com/content/repositories/atlassian-public/com/atlassian/bamboo/atlassian-bamboo-elastic-image/4.2/atlassian-bamboo-elastic-image-4.2.ami
```

5. Open the URL in a browser.
6. The .ami file that opens contains the list of all stock AMI IDs available for the selected version of Bamboo.

Make sure you choose the image from the correct region. For example:

```
image.US_EAST_1.EBS.x86_64.linux.Ubuntu=ami-1c247d74
```

Troubleshooting

If the script above doesn’t work, you can also find the list of Bamboo stock images in the following way:

1. In the following URL:

   https://maven.atlassian.com/content/repositories/atlassian-public/com/atlassian/bamboo/atlassian-bamboo/$BAMBOO_VERSION/atlassian-bamboo-$BAMBOO_VERSION.pom

   change $BAMBOO_VERSION to the Bamboo version number for which you want to list the AMIs.

   Example

   For Bamboo 5.9.3:

   https://maven.atlassian.com/content/repositories/atlassian-public/com/atlassian/bamboo/atlassian-bamboo/5.9.3/atlassian-bamboo-5.9.3.pom

2. Open the URL in a browser.
3. In the atlassian-bamboo-$BAMBOO_VERSION.pom file (where $BAMBOO_VERSION is your version of Bamboo), find the elastic image version for the release. The image version (baseline) is stored as an elastic-image.version property.
Example
For the version 5.9.7 (atlassian-bamboo-5.9.7.pom), the elastic image version was 4.2:

```
<elastic-image.version>4.2</elastic-image.version>
```

4. In the following URL:

```
```

change $ELASTIC_VERSION to the Bamboo elastic version number from Step 3.

Example
For Bamboo elastic version 4.2, which is the baseline for Bamboo 5.9.3:

```
https://maven.atlassian.com/content/repositories/atlassian-public/com/atlassian/bamboo/atlassian-bamboo-elastic-image/4.2/atlassian-bamboo-elastic-image-4.2.ami
```

5. Open the URL in a browser.
6. The .ami file that opens contains the list of all stock AMI IDs available for the selected version of Bamboo.

Make sure you choose the image from the correct region. For example:

```
image.US_EAST_1.EBS.x86_64.linux.Ubuntu=ami-1c247d74
```

Viewing the list of Bamboo stock images v6.4

Bamboo provides a collection of Amazon Machine Images (AMIs) that are ready for use or further customization. Each AMI is identified by its unique ID. For more information about the parameters of the stock images, see Stock images.

Atlassian AMIs and their IDs may change with each minor or major Bamboo release.

- Viewing a list of AMI IDs available for a release
  - Troubleshooting

Viewing a list of AMI IDs available for a release

To generate a list of AMI IDs for a Bamboo version:

1. Save the following script as a .sh file:
if [ $# -eq 0 ]; then
    echo "Usage: `basename $0` [5.8.3] (Your Bamboo version)"
    exit 0
fi

BAMBOO_VERSION=$1
echo For Bamboo version: $BAMBOO_VERSION
ELASTIC_VERSION="$(curl -v --silent
https://maven.atlassian.com/content/groups/public/com/atlassian/
bamboo/atlassian-bamboo/$BAMBOO_VERSION/atlassian-bamboo-$BAMBOO
_VERSION.pom 2>&1 | grep \<elastic-image.version\> | sed -e
's/<[^>]*>//g' -e 's/^[[:space:]]*//' -e 's/^[[:space:]]*$//')"

echo "Elastic bamboo version is $ELASTIC_VERSION"
curl -v --silent
https://maven.atlassian.com/content/groups/public/com/atlassian/
bamboo/atlassian-bamboo-elastic-image/$ELASTIC_VERSION/atlassian
-bamboo-elastic-image-$ELASTIC_VERSION.ami 2>&1 | grep image.
echo "REMEMBER: Use the image from the appropriate region!"

You can also get the script file from this repo.

2. In the terminal, go to the directory where you saved the file and run it with the following command:

   ./<name-of-your-file>.sh <your-bamboo-version>

Example

   ./amis.sh 5.9.3

If you get the "Permission denied" error, you can modify the permissions of the .sh file with the following:

   chmod +x <name-of-the-file>.sh

Results

Click the example to see the full script output.

Example

For Bamboo 5.9.3, the results can be the following:
For Bamboo version: 5.9.3

Elastic bamboo version is 4.2

> GET /content/repositories/atlassian-public/com/atlassian/bamboo/atlassi an-bamboo-elastic-image/4.2/atlassian-bamboo-elastic-image-4.2.ami HTTP/1.1

Troubleshooting

If the script above doesn’t work, you can also find the list of Bamboo stock images in the following way:

1. In the following URL:

   https://maven.atlassian.com/content/groups/public/com/atlassian/bamboo/atlassian-bamboo/$BAMBOO_VERSION/atlassian-bamboo-$BAMBOO _VERSION.pom

   change $BAMBOO_VERSION to the Bamboo version number for which you want to list the AMIs.

   Example

   For Bamboo 5.9.3:

   https://maven.atlassian.com/content/groups/public/com/atlassian/bamboo/atlassian-bamboo/5.9.3/atlassian-bamboo-5.9.3.pom

2. Open the URL in a browser.
3. In the atlassian-bamboo-$BAMBOO_VERSION.pom file (where $BAMBOO_VERSION is your version of Bamboo), find the elastic image version for the release. The image version (baseline) is stored as an elastic-image.version property.

   Example

   For the version 5.9.7 (atlassian-bamboo-5.9.7.pom), the elastic image version was 4.2:
4. In the following URL:

```
https://maven.atlassian.com/content/groups/public/com/atlassian/bamboo/atlassian-bamboo-elastic-image/$ELASTIC_VERSION/atlassian-bamboo-elastic-image-$ELASTIC_VERSION.ami
```

change $ELASTIC_VERSION to the Bamboo elastic version number from Step 3.

**Example**

For Bamboo elastic version 4.2, which is the baseline for Bamboo 5.9.3:

```
https://maven.atlassian.com/content/groups/public/com/atlassian/bamboo/atlassian-bamboo-elastic-image/4.2/atlassian-bamboo-elastic-image-4.2.ami
```

5. Open the URL in a browser.
6. The .ami file that opens contains the list of all stock AMI IDs available for the selected version of Bamboo.

Make sure you choose the image from the correct region. For example:

image.US_EAST_1.EBS.x86_64.linux.Ubuntu=ami-1c247d74

Managing your elastic instances

An **elastic instance** is a running instance of an **elastic image**. One elastic instance is created whenever an elastic image is started. Hence, starting one elastic image multiple times, results in the creation of multiple elastic instances. Each time an elastic instance is created, one elastic agent is created on that instance.

The following list directs you to details on managing elastic instances manually in Bamboo. However, you can configure Bamboo to automatically manage your elastic instances. Please refer to Automatic Elastic Instance Management for more information.

- To view a running elastic instance, see Viewing an elastic instance.
- To access your elastic instance via a client, see Accessing an elastic instance.
- To start one or more elastic instances, see Starting an elastic instance.
- To shut down one or more elastic instances, see Shutting down an elastic instance.
- To configure your Elastic Bamboo settings for elastic instances, see the Elastic Instance Settings section in the Configuring Elastic Instance document.

Viewing an elastic instance

An **elastic instance** is a running instance of an **elastic image**. One elastic instance is created whenever an elastic image is started. Hence, starting one elastic image multiple times, results in the creation of multiple elastic instances. Each time an elastic instance is created, one elastic agent is created on that instance.

Conceptually, an elastic instance can be thought of as a computer. The elastic agent’s processes are run on this computer and the elastic image is the boot hard drive. Unlike computers, however, elastic instances are temporary and stateless. When an elastic instance is shut down:

- Any changes that an elastic instance makes to the boot hard drive (e.g. agent log file) will not persist
- Any customizations to the instance itself will also be lost.

The Amazon Elastic Block Store can provide persistent storage for your elastic instances.

You can also view information about your elastic instances on the AWS Management Console. Please note, we strongly recommend that you use the console for viewing instance information only. You may experience errors if you attempt to manage your instances outside of
To view an elastic instance:

1. Click the icon and select **Elastic Instances**.
2. Click the name of the instance that you want to view, e.g. 'i-05ff716c'.

**Current status**
The status of the elastic instance. Values include, 'Pending' (instance starting up), 'Running' and 'Shutting down'.

**Public DNS**
The public DNS address of the elastic instance. The IP address of the elastic instance is displayed here.

**Start Time**
The start time of the instance, based on the Amazon EC2 timezone (US Eastern Time for Elastic Bamboo). Start time is the time when you sent the request to start an instance, not the time when the instance progresses to 'Running' status. Up time of the instance (including the time taken for the instance to start up) is shown in brackets after the start time.

**Elastic Agent**
The elastic agent process currently running on your elastic instance. Currently, Elastic Bamboo only supports one elastic agent per elastic image. Click the link to view the elastic agent. If the agent is running a job, the job's key will be shown in brackets after the elastic agent name.

**Current Availability Zone**
The availability zone that your elastic instance is running in. Read more about Amazon EC2 availability zones. Your availability zone preference is shown in brackets after the current availability zone. For instructions on how to set the availability zone for your instances, please see Managing your elastic image configurations.

**Attached Volumes**
The IDs of the attached EBS volumes, if you have configured your elastic instances to use EBS.

**Configuration**
The name of the elastic image configuration that was used to create this elastic instance. Click the name to configure the elastic image.

**AMI ID**
The ID of the elastic image (i.e. Amazon Machine Image) that the elastic instance was created from (as part of the elastic image configuration).

**EBS Snapshot ID**
The ID of the EBS snapshot that was used to create the EBS volumes attached to your instance, if you have configured your elastic instances to use EBS.

**Instance Type**
The instance type of your instance.

**SSH Access**
Please see Accessing an elastic instance for information on using this function.

**Accessing Logs**

**Elastic Bamboo › Instances › i-07ec936b**

**Information**

This is an instance running on the Amazon EC2 compute cloud. You can get more extensive information about this instance from the Amazon AWS Web Console.

<table>
<thead>
<tr>
<th>Current status</th>
<th>Running</th>
</tr>
</thead>
</table>

**Public DNS**
e2-184-72-31-22.compute-1.amazonaws.com

IP: 184.72.81.22
Elastic Agent: Elastic Agent on i-07ac936b (Idle)
This is the Bamboo agent that is running in this instance in EC2.

Current Availability Zone: us-east-1c (chosen by EC2)

Attached Volumes:
- vol-fe3c5396

Configuration:
- Configuration: Maven 2.1 Image
- Contains Maven 2.1 and the necessary bits for Selenium 2
- AMI ID: ami-0ab64563
- EBS Snapshot ID: snap-06204c00
- Instance Type: High-CPU Medium

SSH Access:
You can SSH into this instance in the EC2. To do this, simply execute the following command from the bamboo server home directory. Bamboo can not find the elasticbamboo.pk file on the server. For more information on where to find your elasticbamboo.pk file see our online documentation.

```bash
ssh -i elasticbamboo.pk root@ec2-184-72-81-22.compute-1.amazonaws.com
```

Accessing Logs:
You can use SCP to download the logs from this EC2 instance. To do this, simply execute the following command.

```bash
scp -i elasticbamboo.pk root@ec2-184-72-81-22.compute-1.amazonaws.com:/home/bamboo/bamboo-elastic-agent.out ./
```

Amazon EC2 Console:
You can manage your EC2 instances using the Amazon EC2 Console. Once you've logged in through the console, you can access logs for this instance directly. Logs are reproduced below in the iframe below. (note that the logs are usually a little delayed).
Viewing an elastic instance v5.14

An elastic instance is a running instance of an elastic image. One elastic instance is created whenever an elastic image is started. Hence, starting one elastic image multiple times, results in the creation of multiple elastic instances. Each time an elastic instance is created, one elastic agent is created on that instance.

Conceptually, an elastic instance can be thought of as a computer. The elastic agent's processes are run on this computer and the elastic image is the boot hard drive. Unlike computers, however, elastic instances are temporary and stateless. When an elastic instance is shut down:

- Any changes that an elastic instance makes to the boot hard drive (e.g. agent log file) will not persist
- Any customizations to the instance itself will also be lost.

The Amazon Elastic Block Store can provide persistent storage for your elastic instances.

You can also view information about your elastic instances on the AWS Management Console. Please note, we strongly recommend that you use the console for viewing instance information only. You may experience errors if you attempt to manage your instances outside of Bamboo.

You can SSH into this instance in the EC2. To do this, simply execute the following command from the bamboo server home directory. Bamboo cannot find the elasticbamboo.pk file on the server. For more information on where to find your elasticbamboo.pk file see our online documentation.
Accessing an elastic instance

It is possible to connect directly to a running elastic instance to access logs or upload files. Access is available via SSH (secure shell) and file transfer is enabled via SCP (secure copy).

Please note, you can only access elastic instances that are running. You may need to configure the automatic termination of elastic instances.

On this page:
- Using SSH
- Using SCP
- Notes

Related pages:
- Managing your elastic instances

Using SSH

To access your elastic instance using SSH:

1. Navigate to the desired elastic instance, as described on Viewing an elastic instance.
2. Copy the command text listed under the 'SSH Access' section. It will be similar to the following example command text:
   ```
   ssh -i /opt/bamboo/home/xml-data/configuration/elasticbamboo.pk root@ec2-184-72-81-22.compute-1.amazonaws.com
   ```
3. Execute the text in your terminal and you will have full SSH access to the Elastic Instance.

   You can also download the private key via the link in the 'SSH Access' section to access your elastic instance via SSH. Click 'here' in the following text on screen to download the key: 'You can also download the SSH private key file from here and use the private key to access the EC2 instance.'

Using SCP

Note, you can also use SCP to upload files to your elastic instance.

To access your elastic instance using SCP:

1. Navigate to the desired elastic instance, as described on Viewing an elastic instance.
2. Copy the command text listed under the 'Accessing Logs' section. It will be similar to the following example command text:
   ```
   scp -i /opt/bamboo/home/xml-data/configuration/elasticbamboo.pk
   ```
Execute the text in your terminal to download the logs from your elastic instance.

Notes

- **Permission issues for SSH access** — If you are experiencing permission issues when attempting to access your elastic instance via SSH, you may need to use the root user or modify permissions on your Elastic Bamboo private key file. See this FAQ for further details.

Starting an elastic instance

An elastic agent process runs in an elastic instance and will automatically start when an instance is started. If you want to run a Job build on an elastic agent, you can start an elastic instance for the agent to run in. The elastic agent will inherit the capabilities of the image that the instance is started from.

Limitations on the number of elastic instances — An elastic agent is counted as a remote agent for licensing purposes. Hence, if starting an elastic instance (and hence an elastic agent) causes you to exceed the total number of remote agents allowed under your license, you will not be able to start the instance.

To start an elastic instance:

1. Click the icon and select Elastic Instances.
2. Click Start New Elastic Instances.
   - Use Number of instances to specify the number of new instances you would like to start.
   - Use Elastic Image Configuration Name to select the elastic image configuration that you would like your instances to use.
3. Click Submit. The 'Manage Elastic Instances' page will be displayed, showing your new instances starting:
   a. A note will display stating that the elastic instances (and corresponding agents) are starting.
   b. Your elastic instances will then display with a status of 'Pending' while they start up. This generally takes a few minutes.

<table>
<thead>
<tr>
<th>Instance → Agent</th>
<th>Status</th>
<th>Up Time</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance i-2204914b</td>
<td>Pending</td>
<td>8 seconds</td>
<td>View</td>
</tr>
</tbody>
</table>

c. Once your elastic instances have started up, they will progress to 'Running' status. An elastic agent process will then start up for each instance. They will display a status of 'Pending' while they start.

<table>
<thead>
<tr>
<th>Instance → Agent</th>
<th>Status</th>
<th>Up Time</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance i-2204914b</td>
<td>Running</td>
<td>1 minute</td>
<td>View</td>
</tr>
<tr>
<td>Elastic Agent on i-2204914b</td>
<td>Pending</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

d. Once the elastic agents have started, they will display a status of 'Online'.

<table>
<thead>
<tr>
<th>Instance → Agent</th>
<th>Status</th>
<th>Up Time</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance i-2204914b</td>
<td>Running</td>
<td>10 minutes</td>
<td>View</td>
</tr>
<tr>
<td>Elastic Agent on i-2204914b</td>
<td>Online</td>
<td></td>
<td>Disable</td>
</tr>
</tbody>
</table>

Notes

**What if my elastic agent doesn't start?** Bamboo has a set period of time that it waits for the agent to start on an elastic instance. If no response is received by the end of this time period, Bamboo will shut down the elastic instance.

You can configure this time period by modifying the following system property (default is 600):

```
bamboo.agent.elastic.startupTimeoutSeconds
```

Read Starting Bamboo for instructions on how to set a system property.

Scheduling your elastic instances

You can schedule the startup and shutdown of elastic instances in Bamboo. For example, you may wish to shut down all elastic instances on weekends or start up additional instances to help cope with job builds during regular busy periods.
Managing your elastic instance schedules

To manage your elastic instance schedules:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Instance Schedules in the left navigation panel (under 'Elastic Bamboo').
3. Do any of the following:

<table>
<thead>
<tr>
<th>Task</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add a new schedule</td>
<td>Click Add Elastic Instance Schedule to create a schedule from new. Click Copy to use an existing schedule as a template. See the Adding a New Elastic Instance Schedule section below for further instructions.</td>
</tr>
<tr>
<td>Edit an existing schedule</td>
<td>Click Edit for an existing schedule. You can also Delete existing schedules.</td>
</tr>
<tr>
<td>Enable existing schedules</td>
<td>Click Enable for a particular schedule, or click Enable All.</td>
</tr>
<tr>
<td>Disable existing schedules</td>
<td>Click Disable for a particular schedule, or click Disable All.</td>
</tr>
</tbody>
</table>

You can also view the configuration for the elastic image that the instances will be created from, by clicking the image configuration name (e.g. 'Default') in the table of schedules.

Screenshot: Viewing elastic instance schedules

View Elastic Instance Schedules

Configure when to start up or shut down elastic instances of a particular elastic image.

<table>
<thead>
<tr>
<th>Next Scheduled Run</th>
<th>Cron Expression</th>
<th>Image Config</th>
<th>Active Instances</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trigger disabled</td>
<td>Each Saturday at 4:30 am</td>
<td>Stop all elastic instances</td>
<td>Edit</td>
<td>Enable</td>
</tr>
<tr>
<td>Trigger disabled</td>
<td>Each Monday at 9:00 am</td>
<td>Stop all elastic instances</td>
<td>Edit</td>

</tr>
</tbody>
</table>

Adding a new elastic instance schedule

1. Click the icon in the Bamboo header and choose Overview.
2. Click Instance Schedules in the left navigation panel (under 'Elastic Bamboo').
3. Click either Add Elastic Instance Schedule to create a schedule from new, or Copy for an existing schedule to use it as a template.

Enabled
Clear if you do not want this schedule to be enabled when you create it.

**Trigger On**
Choose when this schedule should start:

- **Next Bamboo startup**
- **A cron schedule** — edit Schedule as required. For information on constructing cron expressions, see this FAQ.

**On Trigger Bamboo Should**
Choose the action Bamboo should perform:

- **Stop all elastic instances**
- **Adjust number of active instances**

**Image Config**
Choose which image the elastic instances should be started from. The elastic agents running on the instances will inherit the capabilities from the image.

**Active Instances**
Choose the logical operator and specify a value for the number of active instances.

---

**Add Elastic Instance Schedule**

Choose when your schedule will run and how many elastic instances of a particular configuration you want active at any point in time. When bringing the number of instances down, idle instances will be shut down preferentially. Instances with busy agents will be brought down after the builds they are running have completed.

**Schedule Details**

- **Enabled**
- **Trigger On**
  - **Next Bamboo startup**
  - **A cron schedule**

**Schedule**

- **Daily at 11:50 pm**

**On Trigger Bamboo Should**

- **Stop all elastic instances**
- **Adjust number of active instances**

**Image Config**

- **KBTEST**

**Active Instances**

- **exactly**

Number of instances that Bamboo will attempt to adjust to.

---

**Scheduling your elastic instances v5.14**

You can schedule the startup and shutdown of elastic instances in Bamboo. For example, you may wish to shut down all elastic instances on weekends or start up additional instances to help cope with job builds during regular busy periods.

Managing your elastic instance schedules

To manage your elastic instance schedules:

1. Click the icon in the Bamboo header and choose **Overview**.
2. Click **Instance Schedules** in the left navigation panel (under 'Elastic Bamboo').
3. Do any of the following:

<table>
<thead>
<tr>
<th>Task</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add a new schedule</td>
<td>Click <a href="#">Add Elastic Instance Schedule</a> to create a schedule from new. Click <a href="#">Copy</a> to use an existing schedule as a template. See the Adding a New Elastic Instance Schedule section below for further instructions.</td>
</tr>
<tr>
<td>Edit an existing schedule</td>
<td>Click <a href="#">Edit</a> for an existing schedule. You can also <a href="#">Delete</a> existing schedules.</td>
</tr>
<tr>
<td>Enable existing schedules</td>
<td>Click <a href="#">Enable</a> for a particular schedule, or click <a href="#">Enable All</a>.</td>
</tr>
<tr>
<td>Disable existing schedules</td>
<td>Click <a href="#">Disable</a> for a particular schedule, or click <a href="#">Disable All</a>.</td>
</tr>
</tbody>
</table>

You can also view the configuration for the elastic image that the instances will be created from, by clicking the image configuration name (e.g. 'Default') in the table of schedules.

**View Elastic Instance Schedules**

Configure when to start up or shut down elastic instances of a particular elastic image.

Shutting down an elastic instance
We recommend that you shut down any elastic instances that are not being used. Amazon EC2 charge for the period of time that you have an instance running, so you can minimize your costs simply by shutting down instances with inactive agents. You should also shut down your elastic instances if you are going to restart your Bamboo server, otherwise you will orphan them from your Bamboo server.

If you have set up automated procedures using the Bamboo REST API to terminate agents (e.g. cron jobs), you can also configure Elastic Bamboo to automatically shut down instances after the agent processes terminate.

On this page:
- Shutting down a single elastic instance
- Shutting down all elastic instances
- Configuring automatic shutdown of instances after agent termination
- Shutting down elastic instances using the AWS Console
Shutting down an elastic instance

Before you begin:

- Please ensure that the agent on an elastic instance is not running a job build, before shutting down the instance. Any job builds running on the agent will be abandoned when you shut down the elastic instance.

To shut down an elastic instance:

1. Click the icon and select Elastic Instances.
2. Click Shut Down for the instance that you wish to shut down (in the 'Operations' column).
3. Click Confirm. In the 'Manage Elastic Instances' screen, the elastic instance that you have shut down will show a 'Shutting down' status for a few minutes, before it shuts down and disappears from this screen.

Shutting down all elastic instances

Before you begin:

- Please ensure that the agent on an elastic instance is not running a Job build, before shutting down the instance. Any Job builds running on the agent will be abandoned when you shut down the elastic instance.

To shut down all elastic instances:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Instances in the left navigation panel. The 'Manage Elastic Instances' screen will display.
3. Click Shut Down All Instances. The 'Shut Down All Instances' screen will display.
4. Click Confirm. The 'Manage Elastic Instances' screen will display again. The elastic instances will display 'Shutting down' status for a few minutes, before they shut down and disappear from this screen.

Configuring automatic shutdown of instances after agent termination

To configure Elastic Bamboo to automatically shut down instances when agents are terminated:

Please refer to Configuring Elastic Bamboo and follow the instructions for setting the Automatically shut down elastic instance when elastic agent process ends option in the 'Elastic Bamboo Global Settings' section.

Shutting down elastic instances using the AWS Console

We strongly recommend that you manage your instances using the Elastic Bamboo user interface. If your elastic instances become orphaned from your Bamboo server, you may need to shut your elastic instances down directly in the Amazon Web Services (AWS) console.

Your elastic instances can become orphaned from your Bamboo server, for example if you restart your Bamboo server without shutting down your elastic instances first.

Please refer to How do I shut down my elastic instances if I have restarted my Bamboo server for further details.

Managing your elastic agents

An elastic agent is an agent that runs in the Amazon Elastic Compute Cloud (EC2). An elastic agent process runs in an elastic instance of an elastic image. An elastic agent inherits its capabilities from the elastic image that it was created from.

- To view your elastic agents, see Viewing your elastic agents.
To view elastic agents that have terminated, see Viewing your elastic agent usage history.
To configure your elastic agent’s capabilities, see Configuring elastic agent capabilities.
To disable an elastic agent, see Disabling an elastic agent.

Viewing your elastic agents

An elastic agent is an agent that runs in the Amazon Elastic Compute Cloud (EC2). An elastic agent process runs in an elastic instance of an elastic image. An elastic agent inherits its capabilities from the elastic image that it was created from.

An elastic agent will always have an ‘Online’ status, (i.e. ‘Online’ or ‘Online (Disabled)’). If you disable an elastic agent, the elastic instance will remain online. However, if you shut down the elastic instance, then the elastic agents process is killed and will not appear in the remote agents list. Hence, an elastic agent will never have an ‘Offline’ status.

To view the history of an elastic instance that has been shut down:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Agent History in the left navigation panel.
3. To view the usage history of the elastic agent, click the agent name, or View next to the agent. The ‘Elastic Agent History’ page (see screenshot) will show the following information:
   - Elastic instance — the elastic instance that the elastic agent ran in.
   - Last startup time — the last time that the elastic agent was started. This is based on the Bamboo server time.
   - Last shutdown time — the last time that the elastic instance was stopped. This is based on the Bamboo server time.
   - Up time — the total time that the elastic agent was online.
   - Build History — this table lists the job builds run by the elastic agent and information about the job build, such as the status, duration, test results, etc. You can access the full results by clicking the build number.

Screenshot: Elastic agent history
Configuring elastic agent capabilities

An elastic agent is an agent that runs in the Amazon Elastic Compute Cloud (EC2). An elastic agent process runs in an elastic instance of an elastic image. An elastic agent inherits its capabilities from the elastic image that it was created from.

You can customize the capabilities of your elastic agents by configuring the capabilities on the relevant elastic image.

You may want to configure the capabilities on your elastic image to force your job builds to run on particular elastic agents (e.g. running slow acceptance tests on your most powerful elastic agents). You may also need to configure the capabilities on any custom elastic images that you have created and/or associated with your Bamboo installation.

Please note that adding a builder, JDK or version control capability to the image does not install the actual builders, JDKs or VCS modules on the image. Please take particular note of this, if you are adding capabilities to a custom image.

Related pages:
- Managing your elastic agents

To configure the capabilities on an elastic image:

1. Click the 🔄 icon in the Bamboo header and choose Overview.
2. Click Image configurations in the left navigation panel (under ‘Elastic Bamboo’).
3. Click Capabilities (under ‘Operations’) for the relevant elastic image.
4. Use the ‘Add Capability’ panel at the end of the page to add new capabilities to the image. Please see the following pages for further information:
   - Defining a new executable capability
   - Defining a new JDK capability
   - Defining a new version control capability
   - Defining a new custom capability
   - Defining a new Docker capability
You can also edit, rename or delete a capability from an elastic image. Please see the following pages for further information:

- Configuring capabilities
- Renaming a capability

You can also view the agents and elastic image configurations with a particular capability and the jobs with the related requirement by clicking View for the capability.

Any changes that you have made to elastic image capabilities will only be reflected in new agents started after the changes were made. You will need to restart any existing agents, if you want them to pick up your changes.

Screenshot: Configuring elastic agent capabilities
Disabling an elastic agent

An elastic agent is an agent that runs in the Amazon Elastic Compute Cloud (EC2). An elastic agent process runs in an elastic instance of an elastic image. An elastic agent inherits its capabilities from the elastic image that it was created from.

If you would like to stop an elastic agent, you can disable it in Bamboo. This will abandon any job build it is running and prevent it from running any further job builds.

Please note, disabling an elastic agent will not shut down the elastic instance it is running on (i.e. you will still be charged for the instance uptime). You can permanently stop an elastic agent and instance by shutting down the elastic instance.

The Bamboo server also "supervises" your elastic agents. If the Bamboo server detects that an elastic agent is offline, it will automatically terminate the elastic instance.

Related pages:
- Managing your elastic agents

To disable an elastic agent:

1. Navigate to the desired elastic agent, as described in Viewing your elastic agents.

   ![Instance Agent Table]

<table>
<thead>
<tr>
<th>Instance</th>
<th>Status</th>
<th>Up Time</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instance i-2776e24e</td>
<td>Running</td>
<td>5 minutes</td>
<td>View</td>
</tr>
<tr>
<td>Elastic Agent on i-2776e24e</td>
<td>Online</td>
<td></td>
<td>Disable</td>
</tr>
</tbody>
</table>

   2. Click Disable in the 'Operations' column for the elastic agent. The elastic agent will display with a status of 'Online (Disabled)'.

Re-enable the elastic agent by clicking Enable.

   ![Instance Agent Table]

<table>

</table>

Elastic Bamboo FAQ

This page provides answers to common questions about running builds using Elastic Bamboo. If you are using Elastic Bamboo for the first time, we highly recommend that you read Getting started with Elastic Bamboo for instructions on setting up Elastic Bamboo and running your first build.

What job builds can I run on Elastic Bamboo?

You can run any of your job builds on any elastic agent (which in turn runs on an elastic instance), provided that the elastic agent's capabilities meet the job's requirements. An elastic agent inherits the capabilities of the elastic image it was created from. Hence, you can see which of your jobs can run on elastic agents by checking that your job's requirements match your elastic image's capabilities.

✓ You can view your elastic image and the job builds that meet its requirements on the Agents and plans matrix.
How do I run a plan build and its jobs on an elastic agent?

An elastic agent operates in a similar way to a non-elastic agent. The Bamboo server will determine if any job builds in the queue can be built on any of the available agents (including elastic agents), based on whether or not the capabilities of these agents meet the requirements of these jobs.

If an available elastic agent (like any other available agent) has capabilities which meet the requirements of a build in the build queue, the Bamboo server will assign the job build to that elastic agent.

If you do not have any free elastic agents running, you can configure Bamboo to automatically start up elastic instances whose elastic agents are capable of running job builds in the queue, or you can start up an appropriate elastic instance manually. (When an elastic instance is started, its elastic agent is also started, automatically.) For more information about starting elastic instances manually, refer to Starting an elastic instance.

If you do not use Bamboo’s Automatic Elastic Instance Management feature and prefer to manage your elastic instances manually, then we strongly recommend that you shut down any elastic instances (running your elastic agents), when they are not in use. Minimizing unutilized elastic instance uptime will help reduce costs. Read Shutting down an elastic instance for instructions on how to shut down an elastic instance.

How do I automatically start or shut down elastic instances for job builds?

Bamboo can automatically start elastic instances based on demand from the build queue and shut them down once the elastic agents running on them have been idle for a specified period of time. For more information, please refer to the Automatic Elastic Instance Management section of the Configuring Elastic Bamboo topic.

While Bamboo’s Automatic Elastic Instance Management feature is the easiest and most effective method of managing elastic instances in Bamboo, you can also manage elastic instances using the Bamboo REST API. For example, you could implement cron jobs to intelligently start and stop elastic instances, so that elastic agents are available at key times for your job builds.

How do I know whether my job build was run on an elastic agent?

The name of the image and elastic agent that ran a job build can be viewed as part of the build result. Please see the Viewing a build result page for more information.

How do I customize the capabilities of my elastic agents?

You may want to customize the capabilities of your elastic agents to suit certain jobs in your plans. For example, if you want to force certain job builds to only run on elastic agents, you can add a custom capability of elastic=true to your elastic agents and add the same requirement to these jobs.

To customize the capabilities for your elastic agents, you need to customize the capabilities of the image that they are created from. Read Configuring elastic agent capabilities for instructions.

How much does it cost to run a build?

As Elastic Bamboo usage varies from customer to customer, we cannot provide a definitive cost estimate for running a job build using Elastic Bamboo. We do provide high level guidelines for Elastic Bamboo costs, based on our own experience of using Elastic Bamboo at Atlassian, on the Elastic Bamboo Costs page.

You can significantly reduce the costs and time taken to run a job build by configuring Elastic Bamboo to use Automatic Elastic Instance Management and Amazon’s Elastic Block Store (EBS).

What is EBS and how does it affect my job builds?

The Amazon Elastic Block Store (EBS) provides persistent storage volumes that can be attached to EC2 instances. Elastic Bamboo can use the EBS to store snapshots of relatively static build information, such as checkouts of source code and Maven repository data. You can choose a snapshot to create EBS volumes from. These volumes can then be attached to your elastic instances when they start up.

Disabling Elastic Bamboo
If you do not want to execute Plan builds and their Jobs in the Amazon EC2 anymore, you can disable Elastic Bamboo for your Bamboo installation. Your AWS account details will be preserved when you disable Elastic Bamboo, so you can just enable it if you want to start using it again.

Before you begin:

- Please ensure that you do not require your elastic agents before disabling Elastic Bamboo, as they will be **stopped immediately**.

**To disable Elastic Bamboo:**

1. Click the ![Configuration](image) icon in the Bamboo header and choose **Overview**.
2. Click **Configuration** in the left navigation panel (under 'Elastic Bamboo').
3. Click **Disable**. Elastic Bamboo will be disabled and a confirmation message will be displayed.

**Quick filters**

Use quick filters for handy search shortcuts in your Bamboo build dashboard. Create filters based on configurable rules and never miss a build plan again.

Quick filters work only with plans displayed in Bamboo dashboard, which means that they don't include plan branches.

**Configuration**

Administrators can add, edit, and delete quick filters by clicking the cog icon in the quick filters menu:

![Quick Filters](image)

The configuration view is also available from **Administration > Plans > Quick filters**.

Quick filters are available on the build dashboard for all users of a Bamboo instance.

**Types of rules**

Click a filter name in the build dashboard to display plans that match the rules assigned to the filter.

A plan is displayed only if it matches all the rules specified for a filter.

You can create filters with combinations of the following rules:

<table>
<thead>
<tr>
<th>Rule type name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>By completion date</td>
<td>Displays plans that completed within a specific time frame. For example, you can display plans that completed in the last three days.</td>
</tr>
<tr>
<td>By label</td>
<td>Displays plans with a specific label. You can define multiple labels. The plan is display when it has at least one label specified in the rule. To assign a label to a plan, click the name of a plan to display the plan summary and go to Actions &gt; Modify plan label.</td>
</tr>
<tr>
<td>By name</td>
<td>Displays plans with a specific name or plans that match a regular expression.</td>
</tr>
<tr>
<td>By project</td>
<td>Displays plans that are assigned to a specific project. You can select one or more projects.</td>
</tr>
</tbody>
</table>
### Quick filters v5.14

Use quick filters for handy search shortcuts in your Bamboo build dashboard. Create filters based on configurable rules and never miss a build plan again.

Quick filters work only with plans displayed in Bamboo dashboard, which means that they don’t include plan branches.

#### Configuration

Administrators can add, edit, and delete quick filters by clicking the cog icon in the quick filters menu:

![Build Dashboard](image)

The configuration view is also available from Administration > Plans > Quick filters. Quick filters are available on the build dashboard for all users of a Bamboo instance.

#### Types of rules

Click a filter name in the build dashboard to display plans that match the rules assigned to the filter.

A plan is displayed only if it matches all the rules specified for a filter.

You can create filters with combinations of the following rules:

<table>
<thead>
<tr>
<th>Rule type name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>By completion date</td>
<td>Displays plans that completed within a specific time frame. For example, you can display plans that completed in the last three days.</td>
</tr>
<tr>
<td>By label</td>
<td>Displays plans with a specific label. You can define multiple labels. The plan is displayed when it has at least one label specified in the rule. To assign a label to a plan, click the name of a plan to display the plan summary and go to Actions &gt; Modify plan label.</td>
</tr>
<tr>
<td>By name</td>
<td>Displays plans with a specific name or plans that match a regular expression.</td>
</tr>
<tr>
<td>By project</td>
<td>Displays plans that are assigned to a specific project. You can select one or more projects.</td>
</tr>
</tbody>
</table>
| By result status | Displays plans that have completed with a specific result. You can select from:  
  - Successful  
  - Failed |
| By status | Displays plans based with a specific status. You can select from:  
  - Enabled  
  - Disabled |
Quick filters v6.7

Use quick filters for handy search shortcuts in your Bamboo build dashboard. Create filters based on configurable rules and never miss a build plan again.

Quick filters work only with plans displayed in Bamboo dashboard, which means that they don't include plan branches.

Configuration

Administrators can add, edit, and delete quick filters by clicking the cog icon in the quick filters menu:

The configuration view is also available from Administration > Plans > Quick filters.

Quick filters are available on the build dashboard for all users of a Bamboo instance.

Types of rules

Click a filter name in the build dashboard to display plans that match the rules assigned to the filter.

A plan is displayed only if it matches all the rules specified for a filter.

You can create filters with combinations of the following rules:

<table>
<thead>
<tr>
<th>Rule type name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>By completion date</td>
<td>Displays plans that completed within a specific time frame. For example, you can display plans that completed in the last three days.</td>
</tr>
<tr>
<td>By label</td>
<td>Displays plans with a specific label. You can define multiple labels. The plan is displayed when it has at least one label specified in the rule. To assign a label to a plan, click the name of a plan to display the plan summary and go to Actions &gt; Modify plan label.</td>
</tr>
<tr>
<td>By name</td>
<td>Displays plans with a specific name or plans that match a regular expression.</td>
</tr>
<tr>
<td>By project</td>
<td>Displays plans that are assigned to a specific project. You can select one or more projects.</td>
</tr>
<tr>
<td>By result status</td>
<td>Displays plans that have completed with a specific result. You can select from:   - Successful   - Failed</td>
</tr>
<tr>
<td>By status</td>
<td>Displays plans based with a specific status. You can select from:   - Enabled   - Disabled</td>
</tr>
</tbody>
</table>

Users and permissions

There are several options for managing your Bamboo users and groups:

- Manage locally in Bamboo
- Manage with Atlassian’s Jira applications or Crowd
- Manage with an external user repository, such as LDAP.

On this page:

- Choose a user management option
Choose a user management option

To choose how you want to manage users in Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. Navigate to User repositories (under ‘Security’).
3. Choose one of the user management options:
   - Manage locally in Bamboo
     Managing users
     Managing groups
   - Manage with Atlassian's Jira applications
     Allowing Other Applications to Connect to Jira applications for User Management
   - Manage with Atlassian's Crowd
     Integrating Bamboo with Crowd
   - Manage in a custom external user directory
     Integrating Bamboo with LDAP
4. Click Save.

About users and authors

An author is any person who checks in code to a repository that is associated with a Bamboo plan. An author need not be a Bamboo user.

Depending on your organization's requirements, you can configure Bamboo to grant access to non-users. However, only Bamboo users can:

- view the My Bamboo tab on the Dashboard.
- belong to a group.

About groups

Bamboo groups are used to specify which users will have global permissions and plan permissions. They can also be used to specify which users will receive notifications about a plan's build results. You can create and delete as many groups as you need. You will typically create at least one group per project.

A special group called bamboo-admin is automatically created when you install Bamboo. Members of this group have Bamboo administration rights.

Bamboo permissions

Bamboo permissions control access to plans, builds and administration functions. See Managing permissions.

A plan permission is the ability to perform a particular operation on a plan and its jobs. For each plan, different permissions can be granted to particular groups and/or users. A global permission is the ability to perform a particular operation in relation to Bamboo as a whole.

Managing users

This page describes procedures for managing your Bamboo users locally in Bamboo.

For an brief overview of other options for managing your Bamboo users see Users and permissions.

On this page:

- Create a new user account
- Change a user's password or details

See also:

- Creating new user account
- Changing users' passwords or details
- Granting administration rights to a user
- Deleting or deactivating a user

Create a new user account

Bamboo users can:

- view the **My Bamboo** tab on the **Dashboard**.
- belong to a **group**.

Depending on your organization’s requirements, you can also configure Bamboo to **grant access to non-users**.

**To create a Bamboo user:**

1. Click the **icon** in the Bamboo header and choose **Overview**.
2. Click **Users** in the left navigation panel (under "Security").
3. Complete the ‘Add User’ form:
   - **Username**
     - Username cannot be changed after the user is created.
   - **Password**
     - The user can easily **change their password** later.
   - **Email**
     - The address to which notifications are sent.
   - **Instant Messaging Address**
     - If no IM address is specified, Bamboo will not be able to recognize the user’s **context** when interacting using IM.
   - **Source Repository Aliases**
     - If the user is a Bamboo author, click **Add Alias** to enter the user’s login name for their source-code repository.
     - If you don’t know their login name, they can **specify it themselves** later.

**Change a user’s password or details**

**To change a user’s password or details:**

1. Click the **icon** in the Bamboo header and choose **Overview**.
2. Click **Users** in the left panel (under "Security").
3. Locate the user by typing part of their username, full name or email, and clicking **Search**.
4. Click **Edit** for the required user.
5. Edit the user’s details or password as necessary.
   - If you have configured SMTP email on your Bamboo server, the user will automatically receive an email containing their new password.
   - The user can easily **change their password** later.
6. Click **Save**.

Note that:

- Users who have forgotten their passwords can click the **Forgotten your password?** link on the Bamboo login screen. This will automatically generate a new password and email it to them (provided the Bamboo server has been configured to send SMTP email).
- Logged-in users can change their own password and details, as described in **Managing your user profile**.
- See **Associating your author name with your user profile** for information about **Source Repository Aliases**.

**Creating new user account**

Follow this process if you store the user’s data in Bamboo. If the user data is stored in an external user directory like Crowd or LDAP, go to that directory to perform this action.

Bamboo users can:

- view the **My Bamboo** tab on the **Dashboard**.
• belong to a group.

Depending on your organization's requirements, you can also configure Bamboo to grant access to non-users.

To create a Bamboo user:

1. Click the icon in the Bamboo header and choose Overview.
2. In the left-hand navigation panel, click Users.
3. Click Create user.
4. Complete the 'Add User' form:

   **Username**
   Username cannot be changed after the user is created.

   **Full name**
   User's full name.

   **Email**
   The address to which notifications will be sent.

   **Password**
   The user can easily change their password later.

   **Instant Messaging Address**
   If no IM address is specified, Bamboo will not be able to recognize the user's context when interacting using IM.
5. Click Save.

Changing users' passwords or details

To change a user's password or details:

1. Click the icon in the Bamboo header and choose Overview.
2. In the left-hand navigation panel, click Users.
3. Locate the user by typing part of their username, full name or email, and clicking Search.
4. Next to the user you want to modify, click Edit.
5. Edit the user's details or password as necessary.
   • If you have configured SMTP email on your Bamboo server, the user will automatically receive an email containing their new password.
   • The user can easily change their password later.
6. Click Save.

Note that:

• Users who have forgotten their passwords can click the Forgotten your password? link on the Bamboo login screen. This will automatically generate a new password and email it to them (provided the Bamboo server has been configured to send SMTP email).

• Logged-in users can change their own password and details, as described in Managing your user profile.

• See Associating your author name with your user profile for information about Source Repository Aliases.

Changing usernames

The script below has been used by an Atlassian customer to change a username in Bamboo 3.1. No guarantees are implied by its presence here.
The script below has been used by an Atlassian customer to change a username in Bamboo 3.1. No guarantees are implied by its presence here.
update ACL_ENTRY set SID='newusername' where SID='oldusername';
update ACL_OBJECT_IDENTITY set OWNER_SID='newusername' where OWNER_SID='oldusername';
update AUDIT_LOG set USER_NAME='newusername' where USER_NAME='oldusername';
update AUTHOR set LINKED_USER_NAME='newusername' where LINKED_USER_NAME='oldusername';
update AUTHOR set AUTHOR_NAME='newusername' where AUTHOR_NAME='oldusername';
update AUTH_ATTEMPT_INFO set USER_NAME='newusername' where USER_NAME='oldusername';
update BUILDRESULTSUMMARY_CUSTOMDATA set CUSTOM_INFO_VALUE='newusername'
where CUSTOM_INFO_VALUE='oldusername' &&
CUSTOM_INFO_KEY='ManualBuildTriggerReason.userName';
update BUILDRESULTSUMMARY_LABEL set USER_NAME='newusername' where USER_NAME='oldusername';

update users set name='newusername' where name='oldusername';

Granting administration rights to a user

In Bamboo, there are two types of administrators:

- **Global administrators** — that is, people with the ‘Admin’ global permission. These people can access the Bamboo Administration menu. They can also administer every plan.
- **Plan administrators** — that is, people with the ‘Admin’ and ‘Edit’ plan permissions. These people can administer a particular plan.

**Grant global administration rights**

To grant global administration rights to a user:

- Either grant the ‘Admin’ global permission to the user explicitly (as described in Granting global permissions to users or groups);
- OR:
  - Add the user to a group which has the ‘Admin’ global permission (as described in Changing members of groups).

**Grant plan administration rights**

- Either grant the ‘Admin’ and ‘Edit’ plan permissions to the user explicitly (as described in Granting plan permissions in bulk);
- OR:
  - Add the user to a group which has the ‘Admin’ and ‘Edit’ plan permissions (as described in Changing members of groups).
In Bamboo, there are two types of administrators:

- **Global administrators** — that is, people with the 'Admin' global permission. These people can access the Bamboo Administration menu. They can also administer every plan.
- **Plan administrators** — that is, people with the 'Admin' and 'Edit' plan permissions. These people can administer a particular plan.

### Grant global administration rights

#### To grant global administration rights to a user:

- Either grant the 'Admin' global permission to the user explicitly (as described in Granting global permissions to users or groups);
- OR:
- Add the user to a group which has the 'Admin' global permission (as described in Changing members of groups).

### Related pages:

### Grant plan administration rights

- Either grant the 'Admin' and 'Edit' plan permissions to the user explicitly (as described in Granting plan permissions in bulk);
- OR:
- Add the user to a group which has the 'Admin' and 'Edit' plan permissions (as described in Changing members of groups).

### Deleting or deactivating a user

Deleting a user removes their Bamboo user account. Deactivating a user prevents them from logging in to Bamboo.

### Deleting a Bamboo user
Before you begin:

- Deleting a Bamboo user will not delete their author data — that is, their author statistics and code check-in comments will still exist in Bamboo.
- You cannot delete a user who has created labels or comments about build results. You may want to deactivate them instead.
- You cannot delete the user account with which you are currently logged in to Bamboo.

**On this page:**
- Deleting a Bamboo user
- Deactivating a Bamboo user

**Related pages:**
- Managing users

### To delete a Bamboo user:

1. Click the 
   icon in the Bamboo header and choose Overview.
2. Select Users in the left navigation panel.
3. Use the Delete link in the 'Operations' column.

#### User management

You can use this page to view, update and delete users.

<table>
<thead>
<tr>
<th>Username</th>
<th>Full name</th>
<th>Email</th>
<th>Groups</th>
<th>Source repository aliases</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>

### Deactivating a Bamboo user

You can deactivate a user, which means that they won't receive any email or IM notifications and they won't be able to log in to your Bamboo instance.

Deactivated users can't recover their passwords, but they can still can trigger builds by committing to repositories.

**To deactivate a Bamboo user:**

1. Go to Administration > User management.
2. Find the user that you want to deactivate.
3. Click Edit.
4. Unselect the Active user check box:

   **Username** | **John Smith**
   --------------|-----------------
   **Active user** | **on**

   Active users can log in to the application and will receive email/IM notifications.

5. Click Save.

**Alternative scenario:**

1. Go to Administration > User management.
2. Find the user that you want to deactivate.
3. Click Edit.
4. Enter a new password for the user.
   
   *If you have configured SMTP email on your Bamboo server, the user will automatically receive an email containing their new password.*
5. To get around the email problem, enter an invalid email address in the Email field, for example fooobar@fooobaremailaddress.foobar
6. Delete the user's Instant Messaging Address so that he or she does not receive notifications on build events.
7. Click Save.

Deleting or deactivating a user v5.14
Deleting a user removes their Bamboo user account. Deactivating a user prevents them from logging in to Bamboo.

Deleting a Bamboo user

Before you begin:

- Deleting a Bamboo user will not delete their author data — that is, their author statistics and code check-in comments will still exist in Bamboo.
- You cannot delete a user who has created labels or comments about build results. You may want to deactivate them instead.
- You cannot delete the user account with which you are currently logged in to Bamboo.

On this page:

5. To get around the email problem, enter an invalid email address in the Email field, for example foobar@foobaremailaddress.foobar.
6. Delete the user's Instant Messaging Address so that he or she does not receive notifications on build events.
7. Click Save.

Managing users v6.1

This page describes procedures for managing your Bamboo users locally in Bamboo.

For an brief overview of other options for managing your Bamboo users see Users and permissions.

On this page:

- Create a new user account
- Change a user's password or details

See also:

- Creating new user account
- Changing users' passwords or details
- Granting administration rights to a user
- Deleting or deactivating a user

Create a new user account

Bamboo users can:

- view the My Bamboo tab on the Dashboard.
- belong to a group.

Depending on your organization’s requirements, you can also configure Bamboo to grant access to non-users.

To create a Bamboo user:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Users in the left navigation panel (under 'Security').
3. Complete the 'Add User' form:

   Username
   Username cannot be changed after the user is created.

   Password
   The user can easily change their password later.

   Email
   The address to which notifications are sent.

   Instant Messaging Address
   If no IM address is specified, Bamboo will not be able to recognize the user's context when interacting using IM.

   Source Repository Aliases
   If the user is a Bamboo author, click Add Alias to enter the user's login name for their source-code repository. If you don't know their login name, they can specify it themselves later.

Change a user's password or details

To change a user's password or details:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Users in the left panel (under 'Security').
3. Locate the user by typing part of their username, full name or email, and clicking Search.
4. Click **Edit** for the required user.
5. Edit the user’s details or password as necessary.
   - If you have configured SMTP email on your Bamboo server, the user will automatically receive an email containing their new password.
   - The user can easily change their password later.
6. Click **Save**.

Note that:

- Users who have forgotten their passwords can click the **Forgotten your password?** link on the Bamboo login screen. This will automatically generate a new password and email it to them (provided the Bamboo server has been configured to send SMTP email).
- Logged-in users can change their own password and details, as described in **Managing your user profile**.
- See **Associating your author name with your user profile** for information about **Source Repository Aliases**.

### Managing users v5.14

### Create a new user account

Bamboo users can:

- view the **My Bamboo** tab on the **Dashboard**.
- belong to a **group**.

Depending on your organization’s requirements, you can also configure Bamboo to **grant access to non-users**.

**To create a Bamboo user:**

1. Click the ![icon](image.png) icon in the Bamboo header and choose **Overview**.
2. Click **Users** in the left navigation panel (under 'Security').
3. Complete the 'Add User' form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Username</td>
<td>Username cannot be changed after the user is created.</td>
</tr>
<tr>
<td>Password</td>
<td>The user can easily <strong>change their password</strong> later.</td>
</tr>
<tr>
<td>Email</td>
<td>The address to which notifications are sent.</td>
</tr>
<tr>
<td>Instant Messaging Address</td>
<td>If no IM address is specified, Bamboo will not be able to recognize the user's context when interacting using IM.</td>
</tr>
<tr>
<td>Source Repository Aliases</td>
<td>If the user is a Bamboo author, click <strong>Add Alias</strong> to enter the user's login name for their source-code repository. If you don't know their login name, they can <strong>specify it themselves</strong> later.</td>
</tr>
</tbody>
</table>

### Change a user’s password or details

**To change a user’s password or details:**

1. Click the ![icon](image.png) icon in the Bamboo header and choose **Overview**.
2. Click **Users** in the left panel (under 'Security').
3. Locate the user by typing part of their username, full name or email, and clicking **Search**.
4. Click **Edit** for the required user.
5. Edit the user's details or password as necessary.
   - If you have configured SMTP email on your Bamboo server, the user will automatically receive an email containing their new password.
   - The user can easily change their password later.
6. Click **Save**.

Note that:
- Users who have forgotten their passwords can click the **Forgotten your password?** link on the Bamboo login screen. This will automatically generate a new password and email it to them (provided the Bamboo server has been configured to send SMTP email).
- Logged-in users can change their own password and details, as described in Managing your user profile.
- See Associating your author name with your user profile for information about Source Repository Aliases.

### Managing users v6.6

This page describes procedures for managing your Bamboo users locally in Bamboo.

For a brief overview of other options for managing your Bamboo users, see **Users and permissions**.

If you store a user's data in an external user directory like Crowd or LDAP, you should manage such users in these external directories and not in Bamboo.

### Managing groups

Bamboo groups are used to specify which users will have global permissions and plan permissions. They can also be used to specify which users will receive notifications about a plan's build results. You can create and delete as many groups as you need. You will typically create at least one group per project.

A special group called **bamboo-admin** is automatically created when you install Bamboo. Members of this group have Bamboo administration rights.

Read more about managing groups for your users:
- Creating a group
- Deleting a group
- Changing members of groups

### Creating a group

To create a group:

1. Click the **icon in the Bamboo header and choose Overview**.
2. Click **Groups** (under 'Security') in the left navigation panel.
3. Type a name for your new group into **Group Name** (in the 'Create Group' section). Note that the group name cannot be changed after the group is created.

   In Bamboo, a group name can only contain characters from the following set: a-z, @, ., -, 0-9. You can't create groups that contain invalid character. Similarly, if you try to import of groups that contain invalid characters from an external source, the import of that group will fail.

4. Select relevant users from the **Users to add** list. Hold <Ctrl> to select multiple users. You can also add or remove users from the group later if required.
5. Click **Save**.

**Screenshot: Creating a Bamboo group**
Creating a group v5.14

Bamboo groups are used to specify which users will have global permissions and plan permissions. They can also be used to specify which users will receive notifications about a plan's build results. You can create and delete as many groups as you need. You will typically create at least one group per project.

A special group called bamboo-admin is automatically created when you install Bamboo. Members of this group have Bamboo administration rights.

To create a group:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Groups (under 'Security') in the left navigation panel.
3. Type a name for your new group into Group Name (in the 'Create Group' section). Note that the group name cannot be changed after the group is created.
4. Select relevant users from the Users to add list. Hold <Ctrl> to select multiple users. You can also add or remove users from the group later if required.
5. Click Save.

Screenshot: Creating a Bamboo group
Creating a group v5.15

Bamboo groups are used to specify which users will have global permissions and plan permissions. They can also be used to specify which users will receive notifications about a plan's build results. You can create and delete as many groups as you need. You will typically create at least one group per project.

A special group called bamboo-admin is automatically created when you install Bamboo. Members of this group have Bamboo administration rights.

Connecting to external user directories

Bamboo provides a number of options for connecting to external user directories for user management:

- Manage users and groups in Atlassian's Jira or Atlassian's Crowd — see Integrating Bamboo with Crowd.
- Connect to a custom external user directory, such as an LDAP server — see Integrating Bamboo with LDAP.

You can also manage users and groups within the Bamboo server itself.

Integrating Bamboo with Crowd

Atlassian's Crowd identity management system can be integrated with Bamboo. This allows you to use Crowd as a user directory manager for Bamboo.

The integration process requires you to configure Crowd to talk to Bamboo, then configure Bamboo to talk to Crowd. Hence, the instructions below reference the Crowd documentation. Ensure that you are referring to the correct version of the Crowd documentation.

If you have Jira 4.3 or later, you can also manage your users via Jira. The process for connecting Bamboo to Jira for user management is the same as the process for connecting Bamboo to Crowd for user management (described below).

Bamboo 3.2 should work with versions of Crowd from 2.1 onwards. We recommend Crowd 2.3 or later for performance reasons. Versions earlier than 2.1 are not supported.

On this page:
- Step 1. Configuring Crowd to Talk to Bamboo
- Step 2. Configuring Bamboo to Talk to Crowd
- Notes

Related pages:
- Connecting to external user directories
- Integrating Crowd with Atlassian Bamboo

Step 1. Configuring Crowd to Talk to Bamboo

For instructions on how to configure Crowd to talk to Bamboo, please refer to the Integrating Crowd with Atlassian Bamboo for the latest version of Crowd, which can be found in the Crowd Administrator's Guide. If you are using an older version of Crowd, find the documentation from the Crowd documentation homepage.

Step 2. Configuring Bamboo to Talk to Crowd

1. Click the icon in the Bamboo header and choose Overview.
2. Select User Repositories (under 'Security').
3. Choose Users and groups from Jira or Crowd and configure the connection settings, as follows:

Server URL
Enter the URL of your Crowd server:
If using Crowd 2.1 or older versions: http://localhost:8095/crowd/services/

If using Crowd 2.2 or newer versions: http://localhost:8095/crowd/

If your Crowd server's port is configured differently from the default (8095), set it accordingly.

**Application Name**
Enter the application name that you specified when configuring Crowd in Step 1 above.

**Application Password**
Select Change password and set the password that you specified when configuring Crowd in Step 1 above.

**Cache Refresh Interval**
Set to the number of minutes between requests to validate if the user is logged in or out of the Crowd SSO server. Setting this value to 1 or higher will increase the performance of Crowd's integration.

While valid, setting this value to 0 will cause performance issues on large installations - authentication checks will occur on each request. You can only set it to 0 directly in the xml configuration file.

**Synchronize now**
Click this link to synchronize users and groups from Crowd to Bamboo. Note, this operation may take a long time depending on the number of users that need to be synchronized.

4. **Click Save**

2.1 **Configure External User Management in Bamboo**

If you are connecting Bamboo to an external user management system and do not have rights to update user attributes there, you will need to prevent users from being updated in Bamboo. In this case, you should ensure that the **Read-only External User Management?** check-box is checked. For example, if Crowd directory permissions don't allow any remote changes, then Bamboo will give an error message if an attempt is made to change user account settings. We are tracking this bug:

BAM-12002 - Bamboo should allow changing the IM address and source repository aliases of a user from Crowd

RESOLVED

To configure the external user management option in Bamboo:

1. Navigate to **Administration > Security Settings**.
2. Click **Edit**.
3. Select the **Read-only External User Management?** checkbox. The table below outlines the correct configuration for Bamboo, depending on your external user management setup:

<table>
<thead>
<tr>
<th>External User Management Setup</th>
<th>Read-only External User Management? check-box</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bamboo integrated with — Crowd using the Crowd database (i.e. Internal Directories)</td>
<td>Unchecked</td>
</tr>
<tr>
<td>Bamboo integrated with — Crowd connected to a read-only LDAP</td>
<td>Checked</td>
</tr>
<tr>
<td>Bamboo integrated with — Crowd connected to a read-write LDAP</td>
<td>Unchecked</td>
</tr>
<tr>
<td>Bamboo integrated with — Crowd with authentication-only delegated to LDAP.</td>
<td>Unchecked</td>
</tr>
</tbody>
</table>

4. **Click Save**.

2.2 **Enable Single Sign-On**

Single sign-on (SSO) is optional when integrating Bamboo and other Atlassian products with Crowd. To use centralized authentication without SSO, skip the steps below.

To enable single sign-on (SSO), you will configure Bamboo's authentication and access request calls to use Seraph. To configure Seraph-based authentication:

1. Shut down Bamboo.
2. Edit the `\BAMBOO\atlassian-bamboo\WEB-INF\classes\seraph-config.xml`
3. Comment out the `authenticator` node:

```xml
<!--<authenticator
class="com.atlassian.bamboo.user.authentication.BambooAuthenticator"/>
-->
```

4. Add a new authenticator, by adding the following tag:
<authenticator
class="com.atlassian.crowd.integration.seraph.v25.BambooAuthenticator"/>

5. Start Bamboo. Bamboo’s authentication and access request calls will now be performed using Seraph.

**Notes**

- Test times for synchronizing Bamboo-Crowd — As a guideline, we were able to synchronize 5000 users in six seconds in our internal tests using Crowd 2.3.1. Older versions of Crowd took three minutes to complete the same task.
- If you want to configure the Bamboo-Crowd connection settings manually (e.g. to change the proxy settings), you can find the crowd.properties and atlassian-user.xml files in the $BAMBOO_HOME/xml-data/configuration/ directory.

**Integrating Bamboo with Crowd v5.14**

Atlassian’s Crowd identity management system can be integrated with Bamboo. This allows you to use Crowd as a user directory manager for Bamboo.

The integration process requires you to configure Crowd to talk to Bamboo, then configure Bamboo to talk to Crowd. Hence, the instructions below reference the Crowd documentation. Ensure that you are referring to the correct version of the Crowd documentation.

If you have Jira 4.3 or later, you can also manage your users via Jira. The process for connecting Bamboo to Jira for user management is the same as the process for connecting Bamboo to Crowd for user management (described below).

**Bamboo 3.2** should work with versions of Crowd from 2.1 onwards. We recommend Crowd 2.3 or later for performance reasons. Versions earlier than 2.1 are not supported.

**On this page:**
- Step 1. Configuring Crowd to Talk to Bamboo
- Step 2. Configuring Bamboo to Talk to Crowd
- Notes

**Related pages:**
- Connecting to external user directories
- Integrating Crowd with Atlassian Bamboo

**Step 1. Configuring Crowd to Talk to Bamboo**

For instructions on how to configure Crowd to talk to Bamboo, please refer to the Integrating Crowd with Atlassian Bamboo for the latest version of Crowd, which can be found in the Crowd Administrator’s Guide. If you are using an older version of Crowd, find the documentation from the Crowd documentation homepage.

**Step 2. Configuring Bamboo to Talk to Crowd**

1. Click the icon in the Bamboo header and choose Overview.
2. Select User Repositories (under ‘Security’).
3. Choose Users and groups from Jira or Crowd and configure the connection settings, as follows:

<table>
<thead>
<tr>
<th><strong>Server URL</strong></th>
<th>Enter the URL of your Crowd server:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>If using Crowd 2.1 or older versions:</strong></td>
<td><a href="http://localhost:8095/crowd/services/">http://localhost:8095/crowd/services/</a></td>
</tr>
<tr>
<td><strong>If using Crowd 2.2 or newer versions:</strong></td>
<td><a href="http://localhost:8095/crowd/">http://localhost:8095/crowd/</a></td>
</tr>
<tr>
<td>If your Crowd server’s port is configured differently from the default (8095), set it accordingly.</td>
<td></td>
</tr>
</tbody>
</table>

| **Application Name** | Enter the application name that you specified when configuring Crowd in Step 1 above. |

| **Application Password** | Select Change password and set the password that you specified when configuring Crowd in Step 1 above. |
### Cache Refresh Interval

Set to the number of minutes between requests to validate if the user is logged in or out of the Crowd SSO server. Setting this value to 1 or higher will increase the performance of Crowd's integration. While valid, setting this value to 0 will cause performance issues on large installations - authentication checks will occur on each request. You can only set it to 0 directly in the XML configuration file.

### Synchronize now

Click this link to synchronize users and groups from Crowd to Bamboo. Note, this operation may take a long time depending on the number of users that need to be synchronized.

---

**4. Click Save**

2.1 Configure External User Management in Bamboo: If you are connecting Bamboo to an external user management system and do not have rights to update user attributes there, you will need to prevent users from being updated in Bamboo. In this case, you should ensure that the **Read-only External User Management?** check-box is checked. For example, if Crowd directory permissions don't allow any remote changes, then Bamboo will give an error message if an attempt is made to change user account settings. We are tracking this bug: BAM-12002 - Bamboo should allow changing the IM address and source repository aliases of a user from Crowd.

**RESOLVED**

To configure the external user management option in Bamboo:

1. Navigate to Administration > Security Settings.
2. Click Edit.
3. Select the **Read-only External User Management?** checkbox. The table below outlines the correct configuration for Bamboo, depending on your external user management setup:

<table>
<thead>
<tr>
<th>External User Management Setup</th>
<th>Read-only External User Management? check-box</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bamboo integrated with — Crowd using the Crowd database (i.e. Internal Directories)</td>
<td>Unchecked</td>
</tr>
<tr>
<td>Bamboo integrated with — Crowd connected to a read-only LDAP</td>
<td>Checked</td>
</tr>
<tr>
<td>Bamboo integrated with — Crowd connected to a read-write LDAP</td>
<td>Unchecked</td>
</tr>
<tr>
<td>Bamboo integrated with — Crowd with authentication-only delegated to LDAP.</td>
<td>Unchecked</td>
</tr>
</tbody>
</table>

4. Click Save.

2.2 **Enable Single Sign-On**

Single sign-on (SSO) is optional when integrating Bamboo and other Atlassian products with Crowd. To use centralized authentication without SSO, skip the steps below.

To enable single sign-on (SSO), you will configure Bamboo's authentication and access request calls to use Seraph. To configure Seraph-based authentication:

1. Shut down Bamboo.
2. Edit the `\BAMBOO\atlassian-bamboo\WEB-INF\classes\seraph-config.xml`
3. Comment out the `authenticator` node:

   ```xml
   <!--<authenticator
class="com.atlassian.bamboo.user.authentication.BambooAuthenticator"/>
   -->
   ```

4. Add a new authenticator, by adding the following tag:

   ```xml
   <authenticator
class="com.atlassian.crowd.integration.seraph.v25.BambooAuthenticator"/>
   ```

5. Start Bamboo. Bamboo's authentication and access request calls will now be performed using Seraph.
Notes

- Test times for synchronizing Bamboo-Crowd — As a guideline, we were able to synchronize 5000 users in six seconds in our internal tests using Crowd 2.3.1. Older versions of Crowd took three minutes to complete the same task.
- If you want to configure the Bamboo-Crowd connection settings manually (e.g. to change the proxy settings), you can find the crowd.properties and atlassian-user.xml files in the $BAMBOO_HOME/xml-data/configuration/ directory.

Integrating Bamboo with Crowd v6.1

Atlassian’s Crowd identity management system can be integrated with Bamboo. This allows you to use Crowd as a user directory manager for Bamboo.

The integration process requires you to configure Crowd to talk to Bamboo, then configure Bamboo to talk to Crowd. Hence, the instructions below reference the Crowd documentation. Ensure that you are referring to the correct version of the Crowd documentation.

If you have Jira 4.3 or later, you can also manage your users via Jira. The process for connecting Bamboo to Jira for user management is the same as the process for connecting Bamboo to Crowd for user management (described below).

Bamboo 3.2 should work with versions of Crowd from 2.1 onwards. We recommend Crowd 2.3 or later for performance reasons. Versions earlier than 2.1 are not supported.

On this page:
- Step 1. Configuring Crowd to Talk to Bamboo
- Step 2. Configuring Bamboo to Talk to Crowd
- Notes

Related pages:

- Integrating Crowd with Atlassian Bamboo

Step 1. Configuring Crowd to Talk to Bamboo

For instructions on how to configure Crowd to talk to Bamboo, please refer to the Integrating Crowd with Atlassian Bamboo for the latest version of Crowd, which can be found in the Crowd Administrator's Guide. If you are using an older version of Crowd, find the documentation from the Crowd documentation homepage.

Step 2. Configuring Bamboo to Talk to Crowd

1. Click the icon in the Bamboo header and choose Overview.
2. Select User Repositories (under 'Security').
3. Choose Users and groups from Jira or Crowd and configure the connection settings, as follows:

   **Server URL**
   Enter the URL of your Crowd server:
   - **If using Crowd 2.1 or older versions:** http://localhost:8095/crowd/services/
   - **If using Crowd 2.2 or newer versions:** http://localhost:8095/crowd/
   If your Crowd server's port is configured differently from the default (8095), set it accordingly.

   **Application Name**
   Enter the application name that you specified when configuring Crowd in Step 1 above.

   **Application Password**
   Select Change password and set the password that you specified when configuring Crowd in Step 1 above.

   **Cache Refresh Interval**
   Set to the number of minutes between requests to validate if the user is logged in or out of the Crowd SSO server. Setting this value to 1 or higher will increase the performance of Crowd's integration.
   While valid, setting this value to 0 will cause performance issues on large installations - authentication checks will occur on each request. You can only set it to 0 directly in the xml configuration file.

   **Synchronize now**
   Click this link to synchronize users and groups from Crowd to Bamboo. Note, this operation may take a long time depending on the number of users that need to be synchronized.

4. Click Save

2.1 Configure External User Management in Bamboo if you are connecting Bamboo to an external user management system and do not have rights to update user attributes there, you will need to prevent users from being updated in Bamboo. In this case, you should ensure that the
Read-only External User Management? check-box is checked. For example, if Crowd directory permissions don't allow any remote changes, then Bamboo will give an error message if an attempt is made to change user account settings. We are tracking this bug:

RESOLVED

BAM-12002 - Bamboo should allow changing the IM address and source repository aliases of a user from Crowd.

To configure the external user management option in Bamboo:

1. Navigate to Administration > Security Settings.
2. Click Edit.
3. Select the Read-only External User Management? checkbox. The table below outlines the correct configuration for Bamboo, depending on your external user management setup:

<table>
<thead>
<tr>
<th>External User Management Setup</th>
<th>Read-only External User Management? check-box</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bamboo integrated with — Crowd using the Crowd database (i.e. Internal Directories)</td>
<td>Unchecked</td>
</tr>
<tr>
<td>Bamboo integrated with — Crowd connected to a read-only LDAP</td>
<td>Checked</td>
</tr>
<tr>
<td>Bamboo integrated with — Crowd connected to a read-write LDAP</td>
<td>Unchecked</td>
</tr>
<tr>
<td>Bamboo integrated with — Crowd with authentication-only delegated to LDAP.</td>
<td>Unchecked</td>
</tr>
</tbody>
</table>

4. Click Save.

2.2 (Optional) Enable Single Sign-On

Single sign-on (SSO) is optional when integrating Bamboo and other Atlassian products with Crowd. To use centralized authentication without SSO, skip the steps below.

To enable single sign-on (SSO), you will configure Bamboo's authentication and access request calls to use Seraph. To configure Seraph-based authentication:

1. Shut down Bamboo.
2. Edit the \BAMBOO\atlassian-bamboo\WEB-INF\classes\seraph-config.xml
3. Comment out the authenticator node:

```xml
<authenticator
class="com.atlassian.bamboo.user.authentication.BambooAuthenticator"/>
```

4. Add a new authenticator, by adding the following tag:

```xml
<authenticator
class="com.atlassian.crowd.integration.seraph.v25.BambooAuthenticator"/>
```

5. Start Bamboo. Bamboo's authentication and access request calls will now be performed using Seraph.

Notes

- Test times for synchronizing Bamboo-Crowd — As a guideline, we were able to synchronize 5000 users in six seconds in our internal tests using Crowd 2.3.1. Older versions of Crowd took three minutes to complete the same task.
- If you want to configure the Bamboo-Crowd connection settings manually (e.g. to change the proxy settings), you can find the crowd.properties and atlassian-user.xml files in the $BAMBOO_HOME/xml-data/configuration/ directory.

Integrating Bamboo with Crowd v6.6

You can configure Bamboo to use Atlassian Crowd for user and group management, and for authentication and authorization.

Atlassian Crowd is an application security framework that handles authentication and authorization for your web-based applications. With Crowd you can integrate multiple web applications and user directories, with support for single sign-on (SSO) and centralized identity management. See the Crowd Administration Guide.

Connect to Crowd if you want to use Crowd to manage existing users and groups in multiple directory types, or if you have users of other web-based applications.
To connect Bamboo to Crowd:

1. Log in as a user with 'Admin' permission.
2. In the Bamboo administration area, click User Directories (under 'Security').
3. Click Add Directory and select Atlassian Crowd.
4. Enter settings, as described below.
5. Test and save the directory settings.
6. Define the directory order, on the Directories tab, by clicking the blue up- and down-arrows next to each directory. The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
   - Changes to users and groups will be made only in the first directory where the application has permission to make changes.

Server settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A meaningful name that will help you to identify this Crowd server amongst your list of directory servers. Examples:</td>
</tr>
<tr>
<td></td>
<td>- Crowd Server</td>
</tr>
<tr>
<td></td>
<td>- Example Company Crowd</td>
</tr>
<tr>
<td>Server URL</td>
<td>The web address of your Crowd console server.</td>
</tr>
<tr>
<td></td>
<td>Examples: <a href="http://www.example.com:8095/crowd/">http://www.example.com:8095/crowd/</a></td>
</tr>
<tr>
<td></td>
<td><a href="http://crowd.example.com">http://crowd.example.com</a></td>
</tr>
<tr>
<td>Application Name</td>
<td>The name of your application, as recognized by your Crowd server. Note that you will need to define the application in Crowd too, using the Crowd administration Console. See the Crowd documentaion on adding an application.</td>
</tr>
<tr>
<td>Application Password</td>
<td>The password which the application will use when it authenticates against the Crowd framework as a client. This must be the same as the password you have registered in Crowd for this application. See the Crowd documentation on adding an application.</td>
</tr>
</tbody>
</table>

Crowd permissions

Bamboo offers Read Only permissions for Crowd directories. The users, groups and memberships in Crowd directories are retrieved from Crowd and can only be modified from Crowd. You cannot modify Crowd users, groups or memberships using the Bamboo administration screens.

Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Nested Groups</td>
<td>Enable or disable support for nested groups. Before enabling nested groups, please check to see if the user directory or directories in Crowd support nested groups. When nested groups are enabled, you can define a group as a member of another group. If you are using groups to manage permissions, you can create nested groups to allow inheritance of permissions from one group to its sub-groups.</td>
</tr>
<tr>
<td>Enable Incremental Synchronization</td>
<td>Enable or disable incremental synchronization. Only changes since the last incremental synchronization will be retrieved when synchronizing a directory. Note that full synchronization is always executed when restarting Fisheye.</td>
</tr>
<tr>
<td>Synchronization Interval (minutes)</td>
<td>Synchronization is the process by which the application updates its internal store of user data to agree with the data on the directory server. The application will send a request to your directory server every x minutes, where 'x' is the number specified here. The default value is 60 minutes.</td>
</tr>
</tbody>
</table>
Single sign-on (SSO) with Crowd

Proper tutorial how to enable SSO in Bamboo:
https://confluence.atlassian.com/crowd/integrating-crowd-with-atlassian-bamboo-198785.html#IntegratingCrowdwithAtlassianBamboo-SSO

Using multiple directories

When Bamboo is connected to Crowd you can map Bamboo to multiple user directories in Crowd.

For Crowd 2.8, and later versions, there are two different membership schemes that Crowd can use when multiple directories are mapped to an integrated application, and duplicate user names and group names are used across those directories. The schemes are called ‘aggregating membership’ and ‘non-aggregating membership’ and are used to determine the effective group memberships that Bamboo uses for authorization. See Effective memberships with multiple directories for more information about these two schemes in Crowd.

Note that:
- **Authentication**, for when Bamboo is mapped to multiple directories in Crowd, only depends on the mapped groups in those directories – the aggregation scheme is not involved at all.
- For inactive users, Bamboo only checks if the user is active in the first (highest priority) directory in which they are found to determine authentication. The membership schemes described above are not used when Crowd determines if a user should have access to Bamboo.
- When a user is added to a group, they are only added to the first writeable directory available, in priority order.
- When a user is removed from a group, they are only removed from the group in the first directory the user appears in, when non-aggregating membership is used. With aggregating membership, they are removed from the group in all directories the user exists in.

An administrator can set the aggregation scheme that Bamboo uses when integrated with Crowd. Go to the **Directories** tab for the Bamboo instance in Crowd, and check **Aggregate group memberships across directories** to use the ‘aggregating membership’ scheme. When the checkbox is clear ‘non-aggregating membership’ is used.

Note that changing the aggregation scheme can affect the authorization permissions for your Bamboo users, and how directory update operations are performed.

Integrating Bamboo with LDAP

Bamboo can be integrated with LDAP for the authentication and authorization of LDAP users. The instructions below describe how you can set this up. Please note that Bamboo does not currently support multiple LDAP servers. If you need to connect to multiple LDAP servers, please consider using Atlassian’s **Crowd**.

If you choose to integrate Bamboo with LDAP, please note that you cannot manage LDAP accounts or user groups from Bamboo. Please refer to the instructions on this page for details on how to manage your users and groups.

⚠️ **In Bamboo version 1.2.2 and later, XML backups of your Bamboo instance do not include LDAP user data.**

⚠️ **Please note that once LDAP has been enabled, reverting back to local user management is not possible.**

**On this page:**
- Integrating Bamboo with LDAP
- External User Management
- Delegated LDAP
- Caching
- Notes

**Related pages:**
- Connecting to external user directories
- Knowledge Base articles

**Integrating Bamboo with LDAP**

**Step 1 — Prerequisites**

You will need to confirm that your LDAP server is compatible and set up correctly before integrating it with Bamboo. Please check your LDAP server against the requirements below:

- **Check your LDAP server version** — Supported versions are v2 and v3. Supported LDAP servers include OpenLDAP, Microsoft Active Directory, Novell eDirectory, and any server that uses Java JNDI-LDAP mapping.
- **Check whether your LDAP or Active Directory server supports static groups** — Your LDAP or Active Directory server must support static groups. This means that the user DNs must be stored against a membership attribute inside an LDAP group. An example of a static group is shown below:
The membership attribute in this case is **member**, but this is not required. Note that the full DNs of John Smith and Sally Smith are listed. If the values against **member** are not full DNs, but are just usernames, then you need to add the flag `<useUnqualifiedUsernameForMembershipComparison>true</useUnqualifiedUsernameForMembershipComparison>` to your LDAP configuration. Open Directory on OS X uses this configuration.

- **Ensure that you do not have an LDAP group called 'bamboo-admin'.** — The bamboo-admin group is reserved by Bamboo.
- **Ensure that you do not have duplicate users in your LDAP directory** — If you have users in your LDAP directory that are also on Bamboo, this may cause unpredictable behavior when you attempt to integrate your LDAP server with Bamboo.

**Step 2 — Backup your data**

We strongly recommend that you **backup your data** before attempting LDAP integration.

**Step 3 — Configure Connection Details**

The LDAP server connection is specified by manually editing the file **atlassian-user.xml**.

To configure your connection details:

1. Edit the file `.../{BAMBOO-HOME}/xml-data/configuration/atlassian-user.xml` and configure the connection AD or LDAP.
2. Check your configuration against the example connection details shown below.

```xml
<ldap key="ldapRepository" name="LDAP Repository@hecate.atlassian.com" cache="true">
  <host>hecate.atlassian.com</host>
  <port>389</port>
  <securityPrincipal>cn=admin,dc=atlassian,dc=private</securityPrincipal>
  <securityCredential>secret</securityCredential>
  <securityProtocol>plain</securityProtocol>
  <securityAuthentication>simple</securityAuthentication>
  <baseContext>dc=atlassian,dc=private</baseContext>
  ...
</ldap>
```

You can use the `verifySslCertificateHostname` setting to verify that the SSL certificate of the LDAP server has the same host as the LDAP connection settings:
If the verification fails, the following error is returned in the logs:

Host verification in the LDAP certificate failed. Check whether the hostname in the LDAP connection settings matches the hostname in the server certificate. To disable the validation, set the verifySslCertificateHostname property to 'false' in atlassian-users.xml.

Host verification works only for LDAPS connections, so the securityProtocol setting of the LDAP connection must have an ssl value. Please ensure that the following line is also active in your atlassian-user.xml (it should be there by default):

```xml
<hibernate name="Hibernate Repository" key="hibernateRepository" description="Hibernate Repository" />
```

Step 4 — Map LDAP Data Tree

To map the LDAP Data Tree:

1. To configure the mappings in atlassian-user.xml for either AD or LDAP, please see:
   - Mapping Active Directory
   - Mapping other LDAP servers
2. Check your configuration against the example connection details shown below.

```
<baseUserNamespace>dc=staff,dc=perftest,dc=atlassian,dc=private</baseUserNamespace>

<baseGroupNamespace>dc=groups,dc=perftest,dc=atlassian,dc=private</baseGroupNamespace>
   <usernameAttribute>cn</usernameAttribute>

<userSearchFilter>(objectClass=inetorgperson)</userSearchFilter>
   <firstnameAttribute>givenname</firstnameAttribute>
   <surnameAttribute>sn</surnameAttribute>
   <emailAttribute>mail</emailAttribute>
   <groupnameAttribute>member</groupnameAttribute>
</ldap>
```

Filters: `<userSearchFilter>` and `<groupSearchFilter>` may use the AD specific filter syntax. Operators such as `&` need to be escaped.
Making sure that the LDAP filters are precise
Depending on the LDAP server being used, different object types may have common objectClass values. In this case, please customize the User and Group filters so that Bamboo can fetch only the objects that are really useful for the application. If your directory server does not display the literal object LDIF details, you may want to use an LDAP browser tool like Apache Directory Studio to check if the filters are restricting the objects correctly based on one or more object attributes.

Step 5 — Optional LDAP Settings

The following settings do not appear in the default atlassian-user.xml file. Their default values are as follows:

```xml
<poolingOn>true</poolingOn>
<maxSize>0</maxSize>
<initSize>10</initSize>
<prefSize>10</prefSize>
<debugLevel>none</debugLevel>
<securityProtocol>plain ssl</securityProtocol>
<authentication>simple</authentication>
<timeout>0</timeout>
<initialContextFactory>com.sun.jndi.ldap.LdapCtxFactory</initialContextFactory>
<batchSize>100</batchSize>
<timeToLive>0</timeToLive>
<userSearchAllDepths>true</userSearchAllDepths>
<groupSearchAllDepths>true</groupSearchAllDepths>
<referralStrategy>ignore</referralStrategy>
```

If you want to override these default values, you can specify any or all of them by adding them to the end of the atlassian-user.xml file. For example, to add your own value for the <initSize> setting, you would add an extra line before the `</ldap>` line shown in ‘Stage 3’ above:

```xml
...<initSize>20</initSize>
</ldap>
```

It is important that the connection pool timeout value be set to 0, as this will force Atlassian User (via the JNDI layer) to clean up lingering connections that have lived past one request. For more information about LDAP pools please see [http://java.sun.com/products/jndi/tutorial/ldap/connect/config.html](http://java.sun.com/products/jndi/tutorial/ldap/connect/config.html).

External User Management

You cannot manage LDAP accounts or user groups from Bamboo. Bamboo will continue to use local users and groups, even when LDAP is enabled. If you need to assign LDAP users to particular groups referenced by Bamboo (e.g. for permissions or notifications), the workaround is to assign your LDAP users to local Bamboo groups, and reference these groups rather than LDAP groups.

⚠️ Please note that once LDAP has been enabled, reverting back to local user management is not possible.

1. Click the icon in the Bamboo header and choose Overview.
2. Select User Repositories (under ‘Security’).
3. Choose Custom user repository.
4. Click **Save**.

**Step 1 — Configuring Bamboo for External User Management**

Please ensure that **Read-only External User Management** is turned **OFF** in Bamboo before assigning LDAP users to Bamboo groups. The **Read-only External User Management** check-box in Bamboo controls whether users and groups in Bamboo are editable. Setting this option to **ON** will make users and groups in Bamboo read-only (i.e. the implication being that you will be managing your users and groups externally).

ℹ️ If you are using Crowd together with an LDAP, please read the documentation on Integrating Bamboo with Crowd to see our recommended settings for the **Read-only External User Management** check-box.

**To disable Read-only External User Management:**

1. Click the icon in the Bamboo header and choose **Overview**.
2. Select **Security Settings** (under 'Security') in the left navigation panel.
3. Clear the **Read-only External User Management** check-box.
4. Click **Save**.

**Step 2 — Assigning LDAP Users to Bamboo Groups**

Once Bamboo is started with 'Read-Only External User Management' disabled, you can assign LDAP users to Bamboo groups. Please see Changing members of groups.

⚠️ Please note, the 'View Users' and 'View Groups' screens in Bamboo currently will not list all of your LDAP users/groups (please see BAM-1963 for details).

**Delegated LDAP**

Bamboo does not currently support native delegated LDAP functionality, however an LDAP functionality compromise exists if you are an Atlassian Crowd customer:

1. Configure Crowd to use a **Delegated Authentication Directory**
2. Configure Crowd for Integration with Bamboo using Crowd as the directory for Bamboo.

Note that when using this approach, users will still be required to log in to Crowd at least once before Bamboo is able to read or authenticate from Crowd.

Find out more about Atlassian Crowd, licenses and pricing, or download a 30 day free trial.

**Caching**

For more information about caching, see Configuring the caching of your LDAP repository.

**Notes**

- To check whether the atlassian-user.xml file is correctly configured, please run the Paddle tool to debug the LDAP configuration in your atlassian-user.xml file. For further reference, please visit the Paddle usage page.

**Configuring the caching of your LDAP repository**

The instructions on this page describe how to configure the caching of your LDAP repository.

If you have caching turned on Bamboo will, by default, set the cache to eternal (elements will never expire), and set the maximum number of elements stored to 500. These can be configured to speed up user retrieval, reduce memory usage or reduce the load on the LDAP repository.

**On this page:**

- Controlling the caching of users
- Configuring the LDAP caches

**Related pages:**

- Integrating Bamboo with LDAP
- Testing LDAP or Active Directory connectivity with Paddle

**Controlling the caching of users**

By default, caching is activated for your LDAP users. We recommend that you do not disable caching of your LDAP users, as your LDAP repository may be overloaded by the high volume of requests by Bamboo.

**To control the caching of users:**

1. Edit the `<bamboo-home>/xml-data/configuration/atlassian-user.xml` file
2. To disable caching, set the property `cache="false"` on your LDAP repository, as shown in the example below:
To enable caching, set the property `cache="true"` on your LDAP repository as shown in the example below:

```xml
<ldap key="myLdapRepository" name="LDAP Repository@hecate.atlassian.com" cache="true">
    <host>hecate.atlassian.com</host>
    <port>389</port>
</ldap>
```

Configuring the LDAP caches

Bamboo uses a number of caches for managing an LDAP repository, each of which can be configured differently. You must enable caching, as described above, before configuring the caches. The caches used by Bamboo are:

- Configuring caches for users
- Configuring caches for groups

Each cache can be configured by following the instructions below:

**To configure a cache:**

2. Find the cache that you wish to edit. Examples of each of the caches are described in the Configuring Caches for Users and Configuring Caches for User Groups sections below.
3. Modify the cache, as desired. The following properties can be configured for each cache:
   - `maxElementsInMemory` (mandatory) - Sets the maximum number of objects that will be created in memory
   - `eternal` (mandatory) - Sets whether elements are eternal. If eternal, timeouts are ignored and the element is never expired.
   - `timeToIdleSeconds` (optional) - Sets the time to idle for an element before it expires. i.e. The maximum amount of time between accesses before an element expires. This is only used if the element is not eternal. A value of 0 means that an Element can idle for infinity. The default value is 0.
   - `timeToLiveSeconds` (optional) - Sets the time to live for an element before it expires i.e. The maximum time between creation time and when an element expires. This is only used if the element is not eternal. A value of 0 means that an Element can live for infinity. The default value is 0.

**Configuring caches for users**

In each of the examples below, replace `myLdapRepository` with the key of the repository specified in `atlassian-user.xml`

- LDAPUserManagerReadOnly.*.users stores the individual users, if you have difficulties with Bamboo picking up new user additions in the LDAP repository you will need to alter the configuration of this cache. In the example below, the users will expire after 5 minutes.

```xml
<cache
    name="com.atlassian.user.impl.ldap.LDAPUserManagerReadOnly.myLdapRepository.users"
    maxElementsInMemory="500"
    eternal="false"
    timeToIdleSeconds="300"
    timeToLiveSeconds="300"
/>
```

- LDAPUserManagerReadOnly.*.users_ro stores whether or not the users are read only. This will have no effect on the functionality of Bamboo, but you may wish to modify this cache for performance and memory tuning purposes.

```xml
<cache
    name="com.atlassian.user.impl.ldap.LDAPUserManagerReadOnly.myLdapRepository.users_ro"
    eternal="false"
    timeToIdleSeconds="300"
    timeToLiveSeconds="300"
/>
LDAPUserManagerReadOnly.*.repository stores which repository the user belongs to. Bamboo does not yet support multiple repositories, so modifying this cache will have no effect on functionality. However, you may wish to modify this cache for performance and memory tuning purposes.

Configuring caches for groups

In each of the examples below, replace myLdapRepository with the key of the repository specified in atlassian-user.xml.

LDAPGroupManagerReadOnly.*.groups stores the available groups in LDAP. If you wish Bamboo to pick up changes made to groups, then you will need to configure this cache appropriately.

LDAPGroupManagerReadOnly.*.groups_hasMembership and *LDAPGroupManagerReadOnly.*.groups_getGroupsForUser caches store the associations between users and groups. If you wish Bamboo to pick up changes made to group memberships then you will need to configure these caches appropriately.
Controlling the caching of users

By default, caching is activated for your LDAP users. We recommend that you do not disable caching of your LDAP users, as your LDAP repository may be overloaded by the high volume of requests by Bamboo.

To control the caching of users:

1. Edit the `<bamboo-home>/xml-data/configuration/atlassian-user.xml` file
2. To disable caching, set the property `cache="false"` on your LDAP repository, as shown in the example below:

```xml
<cache
  name="com.atlassian.user.impl.ldap.LDAPGroupManagerReadOnly.myLdapRepository.groups_hasMembership"
  maxElementsInMemory="500"
  eternal="false"
  timeToIdleSeconds="300"
  timeToLiveSeconds="300"
/>
<cache
  name="com.atlassian.user.impl.ldap.LDAPGroupManagerReadOnly.myLdapRepository.groups_getGroupsForUser"
  maxElementsInMemory="500"
  eternal="false"
  timeToIdleSeconds="300"
  timeToLiveSeconds="300"
/>
```
To enable caching, set the property `cache="true"` on your LDAP repository as shown in the example below:

```xml
<ldap key="myLdapRepository" name="LDAP Repository@hecate.atlassian.com" cache="true">
  <host>hecate.atlassian.com</host>
  <port>389</port>
</ldap>
```

**Configuring the LDAP caches**

Bamboo uses a number of caches for managing an LDAP repository, each of which can be configured differently. You must enable caching, as described above, before configuring the caches. The caches used by Bamboo are:

- Configuring caches for users
- Configuring caches for groups

Each cache can be configured by following the instructions below:

**To configure a cache:**

2. Find the cache that you wish to edit. Examples of each of the caches are described in the Configuring Caches for Users and Configuring Caches for User Groups sections below.
3. Modify the cache, as desired. The following properties can be configured for each cache:

   - `maxElementsInMemory` (mandatory) - Sets the maximum number of objects that will be created in memory
   - `eternal` (mandatory) - Sets whether elements are eternal. If eternal, timeouts are ignored and the element is never expired.
   - `timeToIdleSeconds` (optional) - Sets the time to idle for an element before it expires. i.e. The maximum amount of time between accesses before an element expires. This is only used if the element is not eternal. A value of 0 means that an Element can idle for infinity. The default value is 0.
   - `timeToLiveSeconds` (optional) - Sets the time to live for an element before it expires i.e. The maximum time between creation time and when an element expires. This is only used if the element is not eternal. A value of 0 means that an Element can live for infinity. The default value is 0.

**Configuring caches for users**

In each of the examples below, replace `myLdapRepository` with the key of the repository specified in `atlassian-user.xml`.

- `LDAPUserManagerReadOnly.*.users`
  
  `LDAPUserManagerReadOnly.*.users` stores the individual users. If you have difficulties with Bamboo picking up new user additions in the LDAP repository you will need to alter the configuration of this cache. In the example below, the users will expire after 5 minutes.

```xml
<cache name="com.atlassian.user.impl.ldap.LDAPUserManagerReadOnly.myLdapRepository.users">
  maxElementsInMemory="500"
  eternal="false"
  timeToIdleSeconds="300"
  timeToLiveSeconds="300"
</cache>
```

- `LDAPUserManagerReadOnly.*.users_ro`
  
  `LDAPUserManagerReadOnly.*.users_ro` stores whether or not the users are read only. This will have no effect on the functionality of Bamboo, but you may wish to modify this cache for performance and memory tuning purposes.
• LDAPUserManagerReadOnly.*.repository

LDAPUserManagerReadOnly.*.repository stores which repository the user belongs to. Bamboo does not yet support multiple repositories, so modifying this cache will have no effect on functionality. However, you may wish to modify this cache for performance and memory tuning purposes.

• LDAPGroupManagerReadOnly.*.groups

LDAPGroupManagerReadOnly.*.groups stores the available groups in LDAP. If you wish Bamboo to pick up changes made to groups, then you will need to configure this cache appropriately.

• LDAPGroupManagerReadOnly.*.groups_hasMembership and LDAPGroupManagerReadOnly.*.groups_getGroupsForUser

The LDAPGroupManagerReadOnly.*.groups_hasMembership and LDAPGroupManagerReadOnly.*.groups_getGroupsForUser caches store the associations between users and groups. If you wish Bamboo to pick up changes made to group memberships then you will need to configure these caches appropriately.
LDAPGroupManagerReadOnly.myLdapRepository.groups_hasMembership
  maxElementsInMemory="500"
  eternal="false"
  timeToIdleSeconds="300"
  timeToLiveSeconds="300"
 />
<cache
name="com.atlassian.user.impl.ldap.LDAPGroupManagerReadOnly.myLdapRepository.groups_getGroupsForUser"
  maxElementsInMemory="500"
  eternal="false"
  timeToIdleSeconds="300"
  timeToLiveSeconds="300"
 />
<cache
name="com.atlassian.user.impl.ldap.LDAPGroupManagerReadOnly.myLdapRepository.repositories"
  maxElementsInMemory="500"
  eternal="false"
  timeToIdleSeconds="300"
  timeToLiveSeconds="300"
 />

- LDAPGroupManagerReadOnly.myLdapRepository.repositories

LDAPGroupManagerReadOnly.myLdapRepository.repositories stores which repository the group belongs to. Bamboo does not yet support multiple repositories, so modifying this cache will have no effect on functionality. However, you may wish to modify this cache for performance and memory tuning purposes.

---

### Configuring the caching of your LDAP repository v6.6

Testing LDAP or Active Directory connectivity with Paddle

Paddle is a tool that will test the LDAP or Active Directory settings in your atlassian-user.xml.

Using Paddle

You do not need to have Bamboo running to run this tool. The steps are:

1. Download into a directory where you have permissions to create files.
2. Copy your atlassian-user.xml into that directory - this is found in your .../[BAMBOO-HOME]/xml-data/configuration/ directory.
3. Run java -jar paddle-x.x.jar (where x.x is the version of Paddle you downloaded).

### Parameters

Paddle currently supports the following parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Example</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td>java -jar paddle-x.x.jar debug</td>
<td>Prints DEBUG messages to the console as well as paddle.log.</td>
</tr>
</tbody>
</table>

---

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
limit | java -jar paddle-x.x.jar limit=100 | Sets the limit on the number of results returned by user and group queries. Defaults to 10.

Sample output

This is an example of a successful run:

```
#...#...
#...#...
LDAP Support Tool version 1.1
#...#...
#...#...
Connection to LDAP/Active Directory Server at ldap://192.168.0.86:389 SUCCESSFUL.

Integrating Bamboo with LDAP

Testing LDAP or Active Directory connectivity with Paddle v6.7

Paddle is a tool that will test the LDAP or Active Directory settings in your `atlassian-user.xml`.

Using Paddle

You do not need to have Bamboo running to run this tool. The steps are:

1. Download into a directory where you have permissions to create files.
2. Copy your `atlassian-user.xml` into that directory - this is found in your `.../BAMBOO-HOME/xml-data/configuration/` directory.
3. Run `java -jar paddle-x.x.jar` (where x.x is the version of Paddle you downloaded).

On this page:
- Using Paddle
- Parameters
- Sample output
- Notes

Parameters

Paddle currently supports the following parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Example</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td><code>java -jar paddle-x.x.jar debug</code></td>
<td>Prints DEBUG messages to the console as well as paddle.log.</td>
</tr>
<tr>
<td>limit</td>
<td><code>java -jar paddle-x.x.jar limit=100</code></td>
<td>Sets the limit on the number of results returned by user and group queries. Defaults to 10.</td>
</tr>
</tbody>
</table>

Sample output

This is an example of a successful run:

```
########################################################################
#                                                                     #
LDAP Support Tool version 1.1                                        #
#                                                                     #
Connection to LDAP/Active Directory Server at ldap://192.168.0.86:389
SUCCESSFUL.                                                         #
#                                                                     #
TEST 1: Search and list 10 users                                    #
#                                                                     #
User: CN=Administrator                                              #
Member of:                                                           #

Integrating Bamboo with LDAP

Bamboo can be integrated with LDAP for the authentication and authorization of LDAP users. The instructions below describe how you can set this up. Please note that Bamboo does not currently support multiple LDAP servers. If you need to connect to multiple LDAP servers, please consider using Atlassian's Crowd.

If you choose to integrate Bamboo with LDAP, please note that you cannot manage LDAP accounts or user groups from Bamboo. Please refer to the instructions on this page for details on how to manage your users and groups.

⚠️ In Bamboo version 1.2.2 and later, XML backups of your Bamboo instance do not include LDAP user data.

⚠️ Please note that once LDAP has been enabled, reverting back to local user management is not possible.

Integrating Bamboo with LDAP

Step 1 — Prerequisites

You will need to confirm that your LDAP server is compatible and set up correctly before integrating it with Bamboo. Please check your LDAP server against the requirements below:

- **Check your LDAP server version** — Supported versions are v2 and v3. Supported LDAP servers include OpenLDAP, Microsoft Active Directory, Novell eDirectory, and any server that uses Java JNDI-LDAP mapping.

- **Check whether your LDAP or Active Directory server supports static groups** — Your LDAP or Active Directory server must support static groups. This means that the user DNs must be stored against a membership attribute inside an LDAP group. An example of a static group is shown below:

```plaintext
Dn: CN=Sales and Marketing,CN=Users,DC=ad,DC=atlassian,DC=com
objectClass: top; group;
cn: Sales and Marketing;
distinguishedName: CN=Sales and Marketing,CN=Users,DC=ad,DC=atlassian,DC=com;
name: Sales and Marketing;
... 
member: CN=John Smith,CN=Users,DC=ad,DC=atlassian,DC=com
member: CN=Sally Smith,CN=Users,DC=ad,DC=atlassian,DC=com
... 
```

The membership attribute in this case is member, but this is not required. Note that the full DNs of John Smith and Sally Smith are listed. If the values against member are not full DNs, but are just usernames, then you need to add the flag `<useUnqualifiedUsernameForMembershipComparison>true</useUnqualifiedUsernameForMembershipComparison>` to your LDAP configuration. Open Directory on OS X uses this configuration.

- **Ensure that you do not have an LDAP group called 'bamboo-admin'** — The bamboo-admin group is reserved by Bamboo.

- **Ensure that you do not have duplicate users in your LDAP directory** — If you have users in your LDAP directory that are also on Bamboo, the first repository definition in your atlassian-user.xml file will take precedence.

- **Ensure that you do not have duplicate groups in your LDAP directory** — If you have groups in your LDAP directory that are also on Bamboo, this may cause unpredictable behavior when you attempt to integrate your LDAP server with Bamboo.

Step 2 — Backup your data
We strongly recommend that you backup your data before attempting LDAP integration.

**Step 3 — Configure Connection Details**

The LDAP server connection is specified by manually editing the file `atlassian-user.xml`.

To configure your connection details:

1. Edit the file `.../{BAMBOO-HOME}/xml-data/configuration/atlassian-user.xml` and configure the connection AD or LDAP.
2. Check your configuration against the example connection details shown below.

```xml
<ldap key="ldapRepository" name="LDAP Repository@hecate.atlassian.com" cache="true">
  <host>hecate.atlassian.com</host>
  <port>389</port>

  <securityPrincipal>cn=admin,dc=atlassian,dc=private</securityPrincipal>
  <securityCredential>secret</securityCredential>
  <securityProtocol>plain</securityProtocol>
  <securityAuthentication>simple</securityAuthentication>
  <baseContext>dc=atlassian,dc=private</baseContext>
  ...
</ldap>
```

You can use the `verifySslCertificateHostname` setting to verify that the SSL certificate of the LDAP server has the same host as the LDAP connection settings:

```xml
<ldap key="ldapRepository" name="LDAP Repository@hecate.atlassian.com" cache="true">
  <host>ldap.company.com</host>
  <securityProtocol>ssl</securityProtocol>
  ...

  <verifySslCertificateHostname>true</verifySslCertificateHostname>
</ldap>
```

If the verification fails, the following error is returned in the logs:

Host verification in the LDAP certificate failed. Check whether the hostname in the LDAP connection settings matches the hostname in the server certificate. To disable the validation, set the `verifySslCertificateHostname` property to 'false' in `atlassian-users.xml`.

Host verification works only for LDAPS connections, so the `securityProtocol` setting of the LDAP connection must have an `ssl` value.

3. Please ensure that the following line is also active in your `atlassian-user.xml` (it should be there by default):

```xml
<hibernate name="Hibernate Repository" key="hibernateRepository" description="Hibernate Repository" />
```

**Step 4 — Map LDAP Data Tree**

To map the LDAP Data Tree:

1. To configure the mappings in `atlassian-user.xml` for either AD or LDAP, please see:
   - Connecting to an LDAP directory
   - Understanding user management in Confluence
2. Check your configuration against the example connection details shown below.
...<baseUserNamespace>dc=staff,dc=perftest,dc=atlassian,dc=private</baseUserNamespace>
<baseGroupNamespace>dc=groups,dc=perftest,dc=atlassian,dc=private</baseGroupNamespace>
  <usernameAttribute>cn</usernameAttribute>
<userSearchFilter>(objectClass=inetorgperson)</userSearchFilter>
  <firstnameAttribute>givenname</firstnameAttribute>
  <surnameAttribute>sn</surnameAttribute>
  <emailAttribute>mail</emailAttribute>
  <groupnameAttribute>cn</groupnameAttribute>
<groupSearchFilter>(objectClass=groupOfNames)</groupSearchFilter>
  <membershipAttribute>member</membershipAttribute>
</ldap>

Filters: <userSearchFilter> and <groupSearchFilter> may use the AD specific filter syntax. Operators such as & need to be escaped.

Making Sure that the LDAP Filters are Precise
Depending on the LDAP server being used, different object types may have common objectClass values. In this case, please customize the User and Group filters so that Bamboo can fetch only the objects that are really useful for the application. If your directory server does not display the literal object LDIF details, you may want to use an LDAP browser tool like Apache Directory Studio to check if the filters are restricting the objects correctly based on one or more object attributes.

Step 5 — Optional LDAP Settings
The following settings do not appear in the default atlassian-user.xml file. Their default values are as follows:

<poolingOn>true</poolingOn>
<maxSize>0</maxSize>
<initSize>10</initSize>
<prefSize>10</prefSize>
<debugLevel>none</debugLevel>
<securityProtocol>plain ssl</securityProtocol>
<authentication>simple</authentication>
<timeout>0</timeout>
<initialContextFactory>com.sun.jndi.ldap.LdapCtxFactory</initialContextFactory>
<br batchSize>100</batchSize>
<timeToLive>0</timeToLive>
<userSearchAllDepths>true</userSearchAllDepths>
<groupSearchAllDepths>true</groupSearchAllDepths>

If you want to override these default values, you can specify any or all of them by adding them to the end of the atlassian-user.xml file. For example, to add your own value for the <initSize> setting, you would add an extra line before the </ldap> line shown in 'Stage 3'
above:

```xml

...  
    <groupNameAttribute>cn</groupNameAttribute>
    <groupSearchFilter>(objectClass=groupOfNames)</groupSearchFilter>
    <membershipAttribute>member</membershipAttribute>
    <initSize>20</initSize>
</ldap>
```

It is important that the connection pool timeout value be set to 0, as this will force Atlassian User (via the JNDI layer) to clean up lingering connections that have lived past one request. For more information about LDAP pools please see http://java.sun.com/products/jndi/tutorial/ldap/connect/config.html.

External User Management

You cannot manage LDAP accounts or user groups from Bamboo. Bamboo will continue to use local users and groups, even when LDAP is enabled. If you need to assign LDAP users to particular groups referenced by Bamboo (e.g. for permissions or notifications), the workaround is to assign your LDAP users to local Bamboo groups, and reference these groups rather than LDAP groups.

⚠️ Please note that once LDAP has been enabled, reverting back to local user management is not possible.

1. Click the ᄄ icon in the Bamboo header and choose Overview.
2. Select User Repositories (under ‘Security’).
3. Choose Custom user repository.
4. Click Save.

Step 1 — Configuring Bamboo for External User Management

Please ensure that Read-only External User Management is turned OFF in Bamboo before assigning LDAP users to Bamboo groups. The Read-only External User Management check-box in Bamboo controls whether users and groups in Bamboo are editable. Setting this option to ON will make users and groups in Bamboo read-only (i.e. the implication being that you will be managing your users and groups externally).

⚠️ If you are using Crowd together with an LDAP, please read the documentation on Integrating Bamboo with Crowd to see our recommended settings for the Read-only External User Management check-box.

To disable Read-only External User Management:

1. Click the ᄄ icon in the Bamboo header and choose Overview.
2. Select Security Settings (under ‘Security’) in the left navigation panel.
3. Clear the Read-only External User Management check-box.
4. Click Save.

Step 2 — Assigning LDAP Users to Bamboo Groups

Once Bamboo is started with Read-only External User Management disabled, you can assign LDAP users to Bamboo groups. Please see Changing members of groups.

⚠️ Please note, the ‘View Users’ and ‘View Groups’ screens in Bamboo currently will not list all of your LDAP users/groups (please see BAM-1963 for details).

Delegated LDAP

Bamboo does not currently support native delegated LDAP functionality, however an LDAP functionality compromise exists if you are an Atlassian Crowd customer:

1. Configure Crowd to use a Delegated Authentication Directory
2. Configure Crowd for Integration with Bamboo using Crowd as the directory for Bamboo.

Note that when using this approach, users will still be required to log in to Crowd at least once before Bamboo is able to read or authenticate from Crowd.

Find out more about Atlassian Crowd, licenses and pricing, or download a 30 day free trial.

Caching

For more information about caching, see Configuring the caching of your LDAP repository.
Integrating Bamboo with LDAP

Step 1 — Prerequisites

You will need to confirm that your LDAP server is compatible and set up correctly before integrating it with Bamboo. Please check your LDAP server against the requirements below:

- **Check your LDAP server version** — Supported versions are v2 and v3. Supported LDAP servers include OpenLDAP, Microsoft Active Directory, Novell eDirectory, and any server that uses Java JNDI-LDAP mapping.
- **Check whether your LDAP or Active Directory server supports static groups** — Your LDAP or Active Directory server must support static groups. This means that the user DN must be stored against a membership attribute inside an LDAP group. An example of a static group is shown below:

```
Dn: CN=Sales and Marketing,CN=Users,DC=ad,DC=atlassian,DC=com
objectClass: top; group;
  cn: Sales and Marketing;
distinguishedName: CN=Sales and Marketing,CN=Users,DC=ad,DC=atlassian,DC=com;
  name: Sales and Marketing;
  ...;
  member: CN=John Smith,CN=Users,DC=ad,DC=atlassian,DC=com
  member: CN=Sally Smith,CN=Users,DC=ad,DC=atlassian,DC=com
  ...;
```

The membership attribute in this case is `member`, but this is not required. Note that the full DNs of John Smith and Sally Smith are listed. If the values against `member` are not full DNs, but are just usernames, then you need to add the flag `<useUnqualifiedUsernameForMembershipComparison>true</useUnqualifiedUsernameForMembershipComparison>` to your LDAP configuration. Open Directory on OS X uses this configuration.

- **Ensure that you do not have an LDAP group called 'bamboo-admin'.** — The `bamboo-admin` group is reserved by Bamboo.
- **Ensure that you do not have duplicate users in your LDAP directory** — If you have users in your LDAP directory that are also on Bamboo, the first repository definition in your atlassian-user.xml file will take precedence.
- **Ensure that you do not have duplicate groups in your LDAP directory** — If you have groups in your LDAP directory that are also on Bamboo, this may cause unpredictable behavior when you attempt to integrate your LDAP server with Bamboo.

Step 2 — Backup your data

We strongly recommend that you **backup your data** before attempting LDAP integration.

Step 3 — Configure Connection Details

The LDAP server connection is specified by manually editing the file `atlassian-user.xml`. 

Related pages:

- Connecting to external user directories
- Knowledge Base articles
To configure your connection details:

1. Edit the file `/{BAMBOO-HOME}/xml-data/configuration/atlassian-user.xml` and configure the connection AD or LDAP.
2. Check your configuration against the example connection details shown below.

```xml
<ldap key="ldapRepository" name="LDAP Repository@hecate.atlassian.com" cache="true">
  <host>hecate.atlassian.com</host>
  <port>389</port>

  <securityPrincipal>cn=admin,dc=atlassian,dc=private</securityPrincipal>
  <securityCredential>secret</securityCredential>
  <securityProtocol>plain</securityProtocol>
  <securityAuthentication>simple</securityAuthentication>
  <baseContext>dc=atlassian,dc=private</baseContext>

  ...  
</ldap>
```

You can use the `verifySslCertificateHostname` setting to verify that the SSL certificate of the LDAP server has the same host as the LDAP connection settings:

```xml
<ldap key="ldapRepository" name="LDAP Repository@hecate.atlassian.com" cache="true">
  <host>ldap.company.com</host>
  <securityProtocol>ssl</securityProtocol>

  <verifySslCertificateHostname>true</verifySslCertificateHostname>

  ...  
</ldap>
```

If the verification fails, the following error is returned in the logs:

```
Host verification in the LDAP certificate failed. Check whether the hostname in the LDAP connection settings matches the hostname in the server certificate. To disable the validation, set the `verifySslCertificateHostname` property to 'false' in `atlassian-users.xml`.
```

Host verification works only for LDAPS connections, so the `securityProtocol` setting of the LDAP connection must have an `ssl` value.

3. Please ensure that the following line is also active in your `atlassian-user.xml` (it should be there by default):

```xml
<hibernate name="Hibernate Repository" key="hibernateRepository" description="Hibernate Repository" />
```

### Step 4 — Map LDAP Data Tree

To map the LDAP Data Tree:

1. To configure the mappings in `atlassian-user.xml` for either AD or LDAP, see:
   - Connecting to an LDAP directory
   - Understanding user management in Confluence
2. Check your configuration against the example connection details shown below.
<baseUserNamespace>dc=staff,dc=perftest,dc=atlassian,dc=private</baseUserNamespace>

<baseGroupNamespace>dc=groups,dc=perftest,dc=atlassian,dc=private</baseGroupNamespace>

$usernameAttribute>cn</usernameAttribute>

$userSearchFilter>(objectClass=inetorgperson)</userSearchFilter>

$firstnameAttribute>givenname</firstnameAttribute>

$surnameAttribute>sn</surnameAttribute>

$emailAttribute>mail</emailAttribute>

$groupNameAttribute>cn</groupNameAttribute>

$groupSearchFilter>(objectClass=groupOfNames)</groupSearchFilter>

$membershipAttribute>member</membershipAttribute>
</ldap>

Filters: <userSearchFilter> and <groupSearchFilter> may use the AD specific filter syntax. Operators such as & need to be escaped.

$userSearchFilter>(&amp;(objectClass=inetorgperson)(memberOf=cn=bamboo-user,ou=groups,DC=atlassian,dc=com))</userSearchFilter>

Making Sure that the LDAP Filters are Precise
Depending on the LDAP server being used, different object types may have common objectClass values. In this case, please customize the User and Group filters so that Bamboo can fetch only the objects that are really useful for the application. If your directory server does not display the literal object LDIF details, you may want to use an LDAP browser tool like Apache Directory Studio to check if the filters are restricting the objects correctly based on one or more object attributes.

Step 5 — Optional LDAP Settings
The following settings do not appear in the default atlassian-user.xml file. Their default values are as follows:

(poolingOn>true</poolingOn>
<maxSize>0</maxSize>
<initSize>10</initSize>
<prefSize>10</prefSize>
<debugLevel>none</debugLevel>
<securityProtocol>plain ssl</securityProtocol>
<authentication>simple</authentication>
<timeout>0</timeout>
<initialContextFactory>com.sun.jndi.ldap.LdapCtxFactory</initialContextFactory>
=batchSize>100</batchSize>
<timeToLive>0</timeToLive>
</userSearchAllDepths>true</userSearchAllDepths>
</groupSearchAllDepths>true</groupSearchAllDepths>

If you want to override these default values, you can specify any or all of them by adding them to the end of the atlassian-user.xml file. For example, to add your own value for the <initSize> setting, you would add an extra line before the </ldap> line shown in 'Stage 3'.
It is important that the connection pool timeout value be set to 0, as this will force Atlassian User (via the JNDI layer) to clean up lingering connections that have lived past one request. For more information about LDAP pools please see http://java.sun.com/products/jndi/tutorial/ldap/connect/config.html.

External User Management

You cannot manage LDAP accounts or user groups from Bamboo. Bamboo will continue to use local users and groups, even when LDAP is enabled. If you need to assign LDAP users to particular groups referenced by Bamboo (e.g. for permissions or notifications), the workaround is to assign your LDAP users to local Bamboo groups, and reference these groups rather than LDAP groups.

Please note that once LDAP has been enabled, reverting back to local user management is not possible.

1. Click the icon in the Bamboo header and choose Overview.
2. Select User Repositories (under 'Security').
3. Choose Custom user repository.
4. Click Save.

Step 1 — Configuring Bamboo for External User Management

Please ensure that Read-only External User Management is turned OFF in Bamboo before assigning LDAP users to Bamboo groups. The Read-only External User Management check-box in Bamboo controls whether users and groups in Bamboo are editable. Setting this option to ON will make users and groups in Bamboo read-only (i.e. the implication being that you will be managing your users and groups externally).

If you are using Crowd together with an LDAP, please read the documentation on Integrating Bamboo with Crowd to see our recommended settings for the Read-only External User Management check-box.

To disable Read-only External User Management:

1. Click the icon in the Bamboo header and choose Overview.
2. Select Security Settings (under 'Security') in the left navigation panel.
3. Clear the Read-only External User Management check-box.
4. Click Save.

Step 2 — Assigning LDAP Users to Bamboo Groups

Once Bamboo is started with Read-only External User Management disabled, you can assign LDAP users to Bamboo groups. Please see Changing members of groups.

Please note, the 'View Users' and 'View Groups' screens in Bamboo currently will not list all of your LDAP users/groups (please see BAM-1963 for details).

Delegated LDAP

Bamboo does not currently support native delegated LDAP functionality, however an LDAP functionality compromise exists if you are an Atlassian Crowd customer:

1. Configure Crowd to use a Delegated Authentication Directory
2. Configure Crowd for Integration with Bamboo using Crowd as the directory for Bamboo.

Note that when using this approach, users will still be required to log in to Crowd at least once before Bamboo is able to read or authenticate from Crowd.

Find out more about Atlassian Crowd, licenses and pricing, or download a 30 day free trial.

Caching

LDAP caching is not enabled by default in Bamboo. To learn more about enabling this type of caching, see Configuring the caching of your LDAP repository.
Integrating Bamboo with LDAP v6.0

Bamboo can be integrated with LDAP for the authentication and authorization of LDAP users. The instructions below describe how you can set this up. Please note that Bamboo does not currently support multiple LDAP servers. If you need to connect to multiple LDAP servers, please consider using Atlassian’s Crowd.

If you choose to integrate Bamboo with LDAP, please note that you cannot manage LDAP accounts or user groups from Bamboo. Please refer to the instructions on this page for details on how to manage your users and groups.

*In Bamboo version 1.2.2 and later, XML backups of your Bamboo instance do not include LDAP user data.*

*Please note that once LDAP has been enabled, reverting back to local user management is not possible.*

Integrating Bamboo with LDAP

**Step 1 — Prerequisites**

You will need to confirm that your LDAP server is compatible and set up correctly before integrating it with Bamboo. Please check your LDAP server against the requirements below:

- **Check your LDAP server version** — Supported versions are v2 and v3. Supported LDAP servers include OpenLDAP, Microsoft Active Directory, Novell eDirectory, and any server that uses Java JNDI-LDAP mapping.
- **Check whether your LDAP or Active Directory server supports static groups** — Your LDAP or Active Directory server must support static groups. This means that the *user DNs* must be stored against a membership attribute inside an LDAP group. An example of a static group is shown below:

```
Dn: CN=Sales and Marketing,CN=Users,DC=ad,DC=atlassian,DC=com
objectClass: top; group;
cn: Sales and Marketing;
distinguishedName: CN=Sales and Marketing,CN=Users,DC=ad,DC=atlassian,DC=com;
name: Sales and Marketing;
...
member: CN=John Smith,CN=Users,DC=ad,DC=atlassian,DC=com
member: CN=Sally Smith,CN=Users,DC=ad,DC=atlassian,DC=com
...
```

The membership attribute in this case is *member*, but this is not required. Note that the full DNs of John Smith and Sally Smith are listed. If the values against *member* are not full DNs, but are just usernames, then you need to add the flag `<useUnqualifiedUsernameForMembershipComparison>true</useUnqualifiedUsernameForMembershipComparison>` to your LDAP configuration. Open Directory on OS X uses this configuration.

- **Ensure that you do not have an LDAP group called `bamboo-admin`** — The `bamboo-admin` group is reserved by Bamboo.
- **Ensure that you do not have duplicate users in your LDAP directory** — If you have users in your LDAP directory that are also on Bamboo, the first repository definition in your atlassian-user.xml file will take precedence.
- **Ensure that you do not have duplicate groups in your LDAP directory** — If you have groups in your LDAP directory that are also on Bamboo, this may cause unpredictable behavior when you attempt to integrate your LDAP server with Bamboo.

**Step 2 — Backup your data**

We strongly recommend that you backup your data before attempting LDAP integration.

**Step 3 — Configure Connection Details**

The LDAP server connection is specified by manually editing the file `atlassian-user.xml`.

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
To configure your connection details:

1. Edit the file .../{BAMBOO-HOME}/xml-data/configuration/atlassian-user.xml and configure the connection AD or LDAP.
2. Check your configuration against the example connection details shown below.

   ```xml
   <ldap key="ldapRepository" name="LDAP Repository@hecate.atlassian.com" cache="true">
     <host>hecate.atlassian.com</host>
     <port>389</port>
     <securityPrincipal>cn=admin,dc=atlassian,dc=private</securityPrincipal>
     <securityCredential>secret</securityCredential>
     <securityProtocol>plain</securityProtocol>
     <securityAuthentication>simple</securityAuthentication>
     <baseContext>dc=atlassian,dc=private</baseContext>
   </ldap>
   
   You can use the verifySslCertificateHostname setting to verify that the SSL certificate of the LDAP server has the same host as the LDAP connection settings:

   ```xml
   <ldap key="ldapRepository" name="LDAP Repository@hecate.atlassian.com" cache="true">
     <host>ldap.company.com</host>
     <securityProtocol>ssl</securityProtocol>
     <verifySslCertificateHostname>true</verifySslCertificateHostname>
   </ldap>
   
   If the verification fails, the following error is returned in the logs:

   Host verification in the LDAP certificate failed. Check whether the hostname in the LDAP connection settings matches the hostname in the server certificate. To disable the validation, set the verifySslCertificateHostname property to 'false' in atlassian-users.xml.

   Host verification works only for LDAPS connections, so the securityProtocol setting of the LDAP connection must have an ssl value.
3. Please ensure that the following line is also active in your atlassian-user.xml (it should be there by default):

   ```xml
   <hibernate name="Hibernate Repository" key="hibernateRepository" description="Hibernate Repository" />
   ```

**Step 4 — Map LDAP Data Tree**

To map the LDAP Data Tree:

1. To configure the mappings in atlassian-user.xml for either AD or LDAP, please see:
   - Mapping Active Directory
   - Mapping other LDAP servers
2. Check your configuration against the example connection details shown below.
...<baseUserNamespace>dc=staff,dc=perftest,dc=atlassian,dc=private</baseUserNamespace><baseGroupNamespace>dc=groups,dc=perftest,dc=atlassian,dc=private</baseGroupNamespace><usernameAttribute>cn</usernameAttribute><userSearchFilter>(objectClass=inetorgperson)</userSearchFilter><firstnameAttribute>givenname</firstnameAttribute><surnameAttribute>sn</surnameAttribute><emailAttribute>mail</emailAttribute><groupNameAttribute>cn</groupNameAttribute><userSearchFilter>(objectClass=groupOfNames)</userSearchFilter><membershipAttribute>member</membershipAttribute></ldap>

**Filters:** `<userSearchFilter>` and `<groupSearchFilter>` may use the AD specific filter syntax. Operators such as `&` need to be escaped.

```
<userSearchFilter>(&amp;(objectClass=inetorgperson)(memberOf=cn=bamboo-user,ou=groups,DC=atlassian,dc=com))</userSearchFilter>
```

### Making Sure that the LDAP Filters are Precise

Depending on the LDAP server being used, different object types may have common objectClass values. In this case, please customize the User and Group filters so that Bamboo can fetch only the objects that are really useful for the application. If your directory server does not display the literal object LDIF details, you may want to use an LDAP browser tool like Apache Directory Studio to check if the filters are restricting the objects correctly based on one or more object attributes.

### Step 5 — Optional LDAP Settings

The following settings do not appear in the default `atlassian-user.xml` file. Their default values are as follows:

```
<poolingOn>true</poolingOn>
<maxSize>0</maxSize>
<initSize>10</initSize>
<prefSize>10</prefSize>
<debugLevel>none</debugLevel>
<securityProtocol>plain ssl</securityProtocol>
<authentication>simple</authentication>
<timeout>0</timeout>
<initialContextFactory>com.sun.jndi.ldap.LdapCtxFactory</initialContextFactory>
<batchSize>100</batchSize>
<timeToLive>0</timeToLive>
<userSearchAllDepths>true</userSearchAllDepths>
<groupSearchAllDepths>true</groupSearchAllDepths>
<referralStrategy>ignore</referralStrategy>
```
If you want to override these default values, you can specify any or all of them by adding them to the end of the `atlassian-user.xml` file. For example, to add your own value for the `<initSize>` setting, you would add an extra line before the `</ldap>` line shown in 'Stage 3' above:

```xml
...<groupNameAttribute>cn</groupNameAttribute>
<groupSearchFilter>(objectClass=groupOfNames)</groupSearchFilter>
<membershipAttribute>member</membershipAttribute>
<initSize>20</initSize>
</ldap>
```

It is important that the connection pool timeout value be set to 0, as this will force Atlassian User (via the JNDI layer) to clean up lingering connections that have lived past one request. For more information about LDAP pools please see [http://java.sun.com/products/jndi/tutorial/ldap/connect/config.html](http://java.sun.com/products/jndi/tutorial/ldap/connect/config.html).

**External User Management**

You cannot manage LDAP accounts or user groups from Bamboo. Bamboo will continue to use local users and groups, even when LDAP is enabled. If you need to assign LDAP users to particular groups referenced by Bamboo (e.g. for permissions or notifications), the workaround is to assign your LDAP users to local Bamboo groups, and reference these groups rather than LDAP groups.

⚠️ Please note that once LDAP has been enabled, reverting back to local user management is not possible.

1. Click the ![Settings](icon) icon in the Bamboo header and choose Overview.
2. Select **User Repositories** (under 'Security').
3. Choose **Custom user repository**.
4. Click **Save**.

**Step 1 — Configuring Bamboo for External User Management**

Please ensure that **Read-only External User Management** is turned **OFF** in Bamboo before assigning LDAP users to Bamboo groups. The **Read-only External User Management** check-box in Bamboo controls whether users and groups in Bamboo are editable. Setting this option to **ON** will make users and groups in Bamboo read-only (i.e. the implication being that you will be managing your users and groups externally).

⚠️ If you are using Crowd together with an LDAP, please read the documentation on [Integrating Bamboo with Crowd](http://confluence.atlassian.com/5/Integrating_Bamboo_with_Crowd) to see our recommended settings for the **Read-only External User Management** check-box.

**To disable Read-only External User Management:**

1. Click the ![Settings](icon) icon in the Bamboo header and choose Overview.
2. Select **Security Settings** (under 'Security') in the left navigation panel.
3. Clear the **Read-only External User Management** check-box.
4. Click **Save**.

**Step 2 — Assigning LDAP Users to Bamboo Groups**

Once Bamboo is started with **Read-Only External User Management** disabled, you can assign LDAP users to Bamboo groups. Please see [Changing members of groups](http://confluence.atlassian.com/5/Changing_members_of_groups) for details.

⚠️ Please note, the 'View Users' and 'View Groups' screens in Bamboo currently will not list all of your LDAP users/groups (please see [BAM-1963](http://confluence.atlassian.com/5/BAM-1963) for details).

**Delegated LDAP**

Bamboo does not currently support native delegated LDAP functionality, however an LDAP functionality compromise exists if you are an Atlassian Crowd customer:

1. Configure Crowd to use a [Delegated Authentication Directory](http://confluence.atlassian.com/5/Delegated_Authentication_Directory)
2. Configure Crowd for Integration with Bamboo using Crowd as the directory for Bamboo.

Note that when using this approach, users will still be required to log in to Crowd at least once before Bamboo is able to read or authenticate from Crowd.

Find out more about [Atlassian Crowd](http://confluence.atlassian.com/5/Atlassian_Crowd), licenses and pricing, or download a [30 day free trial](http://confluence.atlassian.com/5/30_day_free_trial).

**Caching**
For more information about caching, see Configuring the caching of your LDAP repository.

Notes

- To check whether the atlassian-user.xml file is correctly configured, please run the Paddle tool to debug the LDAP configuration in your atlassian-user.xml file. For further reference, please visit the Paddle usage page.

Integrating Bamboo with LDAP v6.6

You can connect Bamboo to an existing LDAP user directory, so that your existing users and groups in an enterprise directory can be used in Bamboo. The LDAP directory is used for both user authentication and account management.

Bamboo is able to connect to the following LDAP directory servers:

- Microsoft Active Directory
- Apache Directory Server (ApacheDS) 1.0.x and 1.5.x
- Apple Open Directory (Read-Only)
- Fedora Directory Server (Read-Only Posix Schema)
- Novell eDirectory Server
- OpenDS
- OpenLDAP
- OpenLDAP (Read-Only Posix Schema)
- Generic Posix/RFC2307 Directory (Read-Only)
- Sun Directory Server Enterprise Edition (DSEE)
- Any generic LDAP directory server

Synchronization when Bamboo is first connected to the LDAP directory

When you first connect Bamboo to an existing LDAP directory, the Bamboo is synchronized with the LDAP directory. User information, including groups and group memberships, is copied across to the Bamboo database.

Note that when Bamboo is connected to an LDAP directory, you cannot update user details in Bamboo. Updates must be done directly on the LDAP directory, perhaps using a LDAP browser tool such as Apache Directory Studio.

Option - Use LDAP filters to restrict the number of users and groups that are synchronized

You can use LDAP filters to restrict the users and groups that are synchronized with the Bamboo internal directory. You may wish to do this in order to limit the users or groups that can access Bamboo, or if you are concerned that synchronization performance may be poor.

For example, to limit synchronization to just the groups named "Bamboo_user" or "red_team", enter the following into the Group Object Filter field (see Group Schema Settings below):

```
(&(objectClass=group)(|(cn=Bamboo_user)(cn=red_team)))
```

For further discussion about filters, with examples, please see How to write LDAP search filters. Note that you need to know the names for the various containers, attributes and object classes in your particular directory tree, rather than simply copying these examples. You can discover these container names by using a tool such as Apache Directory Studio.

Authentication when a user attempts to log in

When a user attempts to log in to Bamboo, the username and password are passed to the LDAP directory for confirmation. If the password matches that stored for the user, LDAP passes a confirmation back to Bamboo, and Bamboo logs in the user. During the user’s session, all authorizations (i.e. access to Bamboo resources such as repositories, reviews and administration screens) are handled by Bamboo, based on permissions maintained by Bamboo.

Connecting Bamboo
To connect Bamboo to an LDAP directory:

1. Log in as a user with 'Admin' permission.
2. In the Bamboo administration area, click User Directories (under 'Security').
3. Click Add Directory and select either Microsoft Active Directory or LDAP as the directory type.
4. Configure the directory settings, as described in the tables below.
5. Save the directory settings.
6. Define the directory order by clicking the arrows next to each directory on the 'User Directories' screen. The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
   - Changes to users and groups will be made only in the first directory where the application has permission to make changes.

Server settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a meaningful name to help you identify the LDAP directory server. Examples:</td>
</tr>
<tr>
<td></td>
<td>• Example Company Staff Directory</td>
</tr>
<tr>
<td></td>
<td>• Example Company Corporate LDAP</td>
</tr>
<tr>
<td>Directory Type</td>
<td>Select the type of LDAP directory that you will connect to. If you are adding a new LDAP connection, the value you select here will determine the default values for many of the options on the rest of the screen. Examples:</td>
</tr>
<tr>
<td></td>
<td>• Microsoft Active Directory</td>
</tr>
<tr>
<td></td>
<td>• OpenDS</td>
</tr>
<tr>
<td></td>
<td>• And more.</td>
</tr>
<tr>
<td>Hostname</td>
<td>The host name of your directory server. Examples:</td>
</tr>
<tr>
<td></td>
<td>• ad.example.com</td>
</tr>
<tr>
<td></td>
<td>• ldap.example.com</td>
</tr>
<tr>
<td></td>
<td>• opensds.example.com</td>
</tr>
<tr>
<td>Port</td>
<td>The port on which your directory server is listening. Examples:</td>
</tr>
<tr>
<td></td>
<td>• 389</td>
</tr>
<tr>
<td></td>
<td>• 10389</td>
</tr>
<tr>
<td></td>
<td>• 636 (for example, for SSL)</td>
</tr>
<tr>
<td>Use SSL</td>
<td>Check this if the connection to the directory server is an SSL (Secure Sockets Layer) connection. Note that you will need to configure an SSL certificate in order to use this setting.</td>
</tr>
<tr>
<td>Username</td>
<td>The distinguished name of the user that the application will use when connecting to the directory server. Examples:</td>
</tr>
<tr>
<td></td>
<td>• cn=admin,dc=ad,dc=example,dc=com</td>
</tr>
<tr>
<td></td>
<td>• cn=user,dc=domain,dc=name</td>
</tr>
<tr>
<td></td>
<td>• <a href="mailto:user@domain.name">user@domain.name</a></td>
</tr>
</tbody>
</table>

By default, all users can read the uSNCChanged attribute; however, only administrators or users with relevant permissions can access the Deleted Objects container. The specific privileges required by the user to connect to LDAP are "Bind" and "Read" (user info, group info, group membership, update sequence number, deleted objects), which the user can obtain by being a member of the Active Directory's built-in administrators group.

Note that the incremental sync will fail silently if the Active Directory is accessed by a user without these privileges. This has been reported as CWD-3093.
Password

The password of the user specified above.

**Note:** Connecting to an LDAP server requires that this application log in to the server with the username and password configured here. As a result, this password cannot be one-way hashed - it must be recoverable in the context of this application. The password is currently stored in the database in plain text without obfuscation. To guarantee its security, you need to ensure that other processes do not have OS-level read permissions for this application's database or configuration files.

### LDAP schema

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base DN</td>
<td>The root distinguished name (DN) to use when running queries against the directory server. Examples:</td>
</tr>
<tr>
<td></td>
<td>* o=example,c=com</td>
</tr>
<tr>
<td></td>
<td>* cn=users,dc=ad,dc=example,dc=com</td>
</tr>
<tr>
<td></td>
<td>* For Microsoft Active Directory, specify the base DN in the following format: dc=domain1,dc=local. You will need to replace the domain1 and local for your specific configuration. Microsoft Server provides a tool called ldp.exe which is useful for finding out and configuring the the LDAP structure of your server.</td>
</tr>
<tr>
<td>Additional User DN</td>
<td>This value is used in addition to the base DN when searching and loading users. If no value is supplied, the subtree search will start from the base DN. Example:</td>
</tr>
<tr>
<td></td>
<td>* ou=Users</td>
</tr>
<tr>
<td>Additional Group DN</td>
<td>This value is used in addition to the base DN when searching and loading groups. If no value is supplied, the subtree search will start from the base DN. Example:</td>
</tr>
<tr>
<td></td>
<td>* ou=Groups</td>
</tr>
</tbody>
</table>

If no value is supplied for **Additional User DN** or **Additional Group DN** this will cause the subtree search to start from the base DN and, in case of huge directory structure, could cause performance issues for login and operations that rely on login to be performed.

### LDAP permission

| Setting                        | Description                                                                                                                                                                                                 |
|                               |                                                                                                                                                                                                                       |
| Read Only                      | LDAP users, groups and memberships are retrieved from your directory server and can only be modified via your directory server. You cannot modify LDAP users, groups or memberships via the application administration screens. |
| Read Only, with Local Groups   | LDAP users, groups and memberships are retrieved from your directory server and can only be modified via your directory server. You cannot modify LDAP users, groups or memberships via the application administration screens. However, you can add groups to the internal directory and add LDAP users to those groups. |

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Nested Groups</td>
<td>Enable or disable support for nested groups. Some directory servers allow you to define a group as a member of another group. Groups in such a structure are called nested groups. Nested groups simplify permissions by allowing sub-groups to inherit permissions from a parent group.</td>
</tr>
<tr>
<td>Manage User Status Locally</td>
<td>If true, you can activate and deactivate users in Crowd independent of their status in the directory server.</td>
</tr>
</tbody>
</table>
| Filter out expired users | If true, user accounts marked as expired in ActiveDirectory will be automatically removed. For cached directories, the removal of a user will occur during the first synchronization after the account's expiration date.  
**Note:** This is available in Embedded Crowd 2.0.0 and above, but not available in the 2.0.0 m04 release. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Paged Results</td>
<td>Enable or disable the use of the LDAP control extension for simple paging of search results. If paging is enabled, the search will retrieve sets of data rather than all of the search results at once. Enter the desired page size – that is, the maximum number of search results to be returned per page when paged results are enabled. The default is 1000 results.</td>
</tr>
<tr>
<td>Follow Referrals</td>
<td>Choose whether to allow the directory server to redirect requests to other servers. This option uses the node referral (JNDI lookup <code>java.naming.referral</code>) configuration setting. It is generally needed for Active Directory servers configured without proper DNS, to prevent a <code>javax.naming.PartialResultException: Unprocessed Continuation Reference(s)</code> error.</td>
</tr>
</tbody>
</table>
| Naive DN Matching      | If your directory server will always return a consistent string representation of a DN, you can enable naive DN matching. Using naive DN matching will result in a significant performance improvement, so we recommend enabling it where possible.  
This setting determines how your application will compare DNs to determine if they are equal.  
- If this checkbox is selected, the application will do a direct, case-insensitive, string comparison. This is the default and recommended setting for Active Directory, because Active Directory guarantees the format of DNs.  
- If this checkbox is not selected, the application will parse the DN and then check the parsed version. |
| Enable Incremental Synchronization | Enable incremental synchronization if you only want changes since the last synchronization to be queried when synchronizing a directory.  
**⚠️ Please be aware that when using this option, the user account configured for synchronization must have read access to:**  
- The `uSNCchanged` attribute of all users and groups in the directory that need to be synchronized.  
- The objects and attributes in the Active Directory deleted objects container.  
If at least one of these conditions is not met, you may end up with users who are added to (or deleted from) the Active Directory not being respectively added (or deleted) in the application.  
This setting is only available if the directory type is set to "Microsoft Active Directory". |
| Synchronization Interval (minutes) | Synchronization is the process by which the application updates its internal store of user data to agree with the data on the directory server. The application will send a request to your directory server every x minutes, where 'x' is the number specified here. The default value is 60 minutes. |
| Read Timeout (seconds)  | The time, in seconds, to wait for a response to be received. If there is no response within the specified time period, the read attempt will be aborted. A value of 0 (zero) means there is no limit. The default value is 120 seconds. |
| Search Timeout (seconds) | The time, in seconds, to wait for a response from a search operation. A value of 0 (zero) means there is no limit. The default value is 60 seconds. |
### User schema settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>User Object Class</strong></td>
<td>This is the name of the class used for the LDAP user object. Example:</td>
</tr>
<tr>
<td></td>
<td>• user</td>
</tr>
<tr>

</tr>
</tbody>
</table>

### Connecting to external user directories v6.6

You can connect Bamboo to external user directories. This allows you to use existing users and groups stored in an enterprise directory, and to manage those users and groups in one place.

User management functions include:

- **Authentication**: determining which user identity is sending a request to Bamboo.
- **Authorization**: determining the access privileges for an authenticated user.
• **User management:** maintaining profile information in user’s accounts.
• **Group membership:** storing and retrieving groups, and group membership.

It is important to understand that these are separate components of a user management system. You could use an external directory for any or all of the above tasks.

There are several approaches to consider when using external user directories with Bamboo, described briefly below:

• **LDAP**
• **Crowd**
• **Multiple directories**

**LDAP**

You should consider connecting to an LDAP directory server if your users and groups are stored in an enterprise directory.

There are two common ways of using an external LDAP directory with Bamboo:

• For full user and group management, including for user authentication — see Connecting to an existing LDAP directory for instructions.
• For delegated user authentication only, while using Bamboo’s internal directory for user and group management — see Delegating authentication to an LDAP directory for instructions.

Bamboo is able to connect to the following LDAP directory servers:

• Microsoft Active Directory
• Apache Directory Server (ApacheDS) 1.0.x and 1.5.x
• Apple Open Directory (Read-Only)
• Fedora Directory Server (Read-Only Posix Schema)
• Novell eDirectory Server
• OpenDS
• OpenLDAP
• OpenLDAP (Read-Only Posix Schema)
• Generic Posix/RFC2307 Directory (Read-Only)
• Sun Directory Server Enterprise Edition (DSEE)
• Any generic LDAP directory server

**Crowd**

You can connect Bamboo to Atlassian Crowd for user and group management, as well as for user authentication.

Crowd is an application security framework that handles authentication and authorization for your web-based applications. With Crowd you can integrate multiple web applications with multiple user directories, with support for single sign-on (SSO) and centralized identity management. See the Crowd Administration Guide.

You should consider connecting to Crowd if you want to use Crowd to manage existing users and groups in multiple directory types, or if you have users of other web-based applications.

See Connecting to Crowd for configuration instructions.

**Multiple directories**

When Bamboo is connected directly to multiple user directories, where duplicate user names and group names are used across those directories, the effective group memberships that Bamboo uses for authorization can be determined using either of these two schemes:

• ‘aggregating membership’
• ‘non-aggregating membership’.

See Effective memberships with multiple directories for more information about these two schemes.

Note that:

• Aggregating membership is used by default for new installations of Bamboo.
• Authentication, for when Bamboo is connected to multiple directories, only depends on the mapped groups in those directories — the aggregation scheme is not involved at all.
• The directory order is significant during the authentication of the user, in cases where the same user exists in multiple directories. When a user attempts to log in, the application will search the directories in the order specified, and will use the credentials (password) of the first occurrence of the user to validate the login attempt.
• For inactive users, Bamboo only checks if the user is active in the first (highest priority) directory in which they are found for the purpose of determining authentication. Whether a user is active or inactive does not affect how their memberships are determined.
• When a user is added to a group, they are only added to the first writeable directory available, in priority order.
• When a user is removed from a group, they are only removed from the group in the first directory the user appears in, when non-aggregating membership is used. With aggregating membership, they are removed from the group in all directories the user exists in.
• When using Single Sign-On with Crowd and multiple Crowd directories:
  • signed-in users will be validated against the first Crowd directory the user is in
  • users that haven't signed in yet, but have a valid Crowd SSO cookie will be validated against all configured Crowd directories in order

A Bamboo admin can change the membership scheme used by Bamboo using the following commands:

• To change to aggregating membership, substitute your own values for <username>, <password> and <base-url> in this command:
  
  ```
curl -H 'Content-type: application/json' -X PUT -d 
  '{"membershipAggregationEnabled":true}' -u <username>:<password> 
  <base-url>/rest/crowd/latest/application
  ```

• To change to non-aggregating membership, substitute your own values for <username>, <password> and <base-url> in this command:
  
  ```
curl -H 'Content-type: application/json' -X PUT -d 
  '{"membershipAggregationEnabled":false}' -u 
  <username>:<password> <base-url>/rest/crowd/latest/application
  ```

Note that these operations are different from how you make these changes in Crowd. Note also that changing the aggregation scheme can affect the authorization permissions for your users, and how directory update operations are performed.

Connecting to external user directories v5.14

Bamboo provides a number of options for connecting to external user directories for user management:

• Manage users and groups in Atlassian's JIRA or Atlassian's Crowd — see Integrating Bamboo with Crowd.
• Connect to a custom external user directory, such as an LDAP server — see Integrating Bamboo with LDAP.

You can also manage users and groups within the Bamboo server itself.

Connecting Bamboo to JIRA for user management

⚠️ This page does not apply to JIRA Software Cloud; you can’t use JIRA Software Cloud to manage your Bamboo users.

You can connect Bamboo to an existing Atlassian JIRA Software instance to delegate Bamboo user and group management, and authentication. Bamboo provides a "read-only" connection to JIRA Software for user management. This means that users and groups, fetched from JIRA Software, can only be modified or updated in that JIRA Software server, rather than in Bamboo.

Choose this option, as an alternative to Atlassian Crowd, for simple configurations with a limited number of users. Note that Bamboo can only connect to an instance running JIRA Software 4.3 or later.

Connecting Bamboo and JIRA Software is a 3-step process:

1. Set up JIRA Software to allow connections from Bamboo
2. Set up Bamboo to connect to JIRA Software
3. Set up Bamboo users and groups in JIRA Software

Also on this page:

• Server settings
• JIRA Software server permissions
• Advanced settings

⚠️ You need to be an administrator in JIRA Software and a system administrator in Bamboo to perform the following tasks.

1. Setup JIRA Software to allow connections from Bamboo
1. Log in as a user with the 'JIRA Software Administrators' global permission.
2. For JIRA 4.3.x, select Other Application from the 'Users, Groups & Roles' section of the 'Administration' menu.
   For later versions, choose Administration > Users > JIRA User Server.
3. Click Add Application.
4. Enter the application name (case-sensitive) and password that Bamboo will use when accessing JIRA Software.
5. Enter the IP address of your Bamboo instance. Valid values are:
   - A full IP address, e.g. 192.168.10.12.
   - A wildcard IP range, using CIDR notation, e.g. 192.168.10.1/16. For more information, see the introduction to CIDR notation on Wikipedia and RFC 4632.
6. Click Save.
7. Define the directory order, on the 'User Directories' screen, by clicking the blue up- and down-arrows next to each directory. The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
   - Changes to users and groups will be made only in the first directory where the application has permission to make changes.

2. Setup Bamboo to connect to JIRA Software

1. Log in to Bamboo as a user with 'Admin' permission.
2. In the Bamboo administration area click User Directories (under 'Security').
3. Click Add Directory and select Atlassian JIRA.
4. Enter settings, as described below.
5. Test and save the directory settings.
6. Define the directory order, on the 'User Directories' screen, by clicking the arrows for each directory. The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
   - Changes to users and groups will be made only in the first directory where the application has permission to make changes.

3. Set up Bamboo users and groups in JIRA Software

In order to use Bamboo, users must be a member of the Bamboo-users group or have Bamboo global permissions. Follow these steps to configure your Bamboo groups in JIRA Software:

1. Add the bamboo-users and bamboo-administrators groups in JIRA Software.
2. Add your own username as a member of both of the above groups.
3. Choose one of the following methods to give your existing JIRA Software users access to Bamboo:
   - Option 1: In JIRA Software, find the groups that the relevant users belong to. Add those groups as members of one or both of the above Bamboo groups.
   - Option 2: Log in to Bamboo using your JIRA Software account and go to the administration area. Click Global permissions (under 'Security'). Assign the appropriate permissions to the relevant JIRA Software groups. See Global permissions.

Connecting Atlassian Bamboo to JIRA Software for user management is not sufficient, by itself, to allow your users to log in to Bamboo. You must also grant them access to Bamboo by using one of the above 2 options.

We recommend that you use groups instead of individual accounts when granting permissions.

## Connecting Bamboo to JIRA for user management v5.14

⚠️ This page does not apply to JIRA Software Cloud; you can’t use JIRA Software Cloud to manage your Bamboo users.

You can connect Bamboo to an existing Atlassian JIRA Software instance to delegate Bamboo user and group management, and authentication. Bamboo provides a "read-only" connection to JIRA Software for user management. This means that users and groups, fetched from JIRA Software, can only be modified or updated in that JIRA Software server, rather than in Bamboo.

Choose this option, as an alternative to Atlassian Crowd, for simple configurations with a limited number of users. Note that Bamboo can only connect to an instance running JIRA Software 4.3 or later.

Connecting Bamboo and JIRA Software is a 3-step process:

1. Set up JIRA Software to allow connections from Bamboo
2. Set up Bamboo to connect to JIRA Software
3. Set up Bamboo users and groups in JIRA Software

Also on this page:
- Server settings
- JIRA Software server permissions
- Advanced settings

⚠️ You need to be an administrator in JIRA Software and a system administrator in Bamboo to perform the following tasks.

### 1. Setup JIRA Software to allow connections from Bamboo

1. Log in as a user with the 'JIRA Software Administrators' global permission.
2. For JIRA 4.3.x, select Other Application from the ‘Users, Groups & Roles’ section of the ‘Administration’ menu. For later versions, choose Administration > Users > JIRA User Server.
3. Click Add Application.
4. Enter the application name (case-sensitive) and password that Bamboo will use when accessing JIRA Software.
5. Enter the IP address of your Bamboo instance. Valid values are:
   - A full IP address, e.g. 192.168.10.12.
   - A wildcard IP range, using CIDR notation, e.g. 192.168.10.1/16. For more information, see the introduction to CIDR notation on Wikipedia and RFC 4632.
6. Click Save.
7. Define the directory order, on the 'User Directories' screen, by clicking the blue up- and down-arrows next to each directory. The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
   - Changes to users and groups will be made only in the first directory where the application has permission to make changes.

### 2. Setup Bamboo to connect to JIRA Software

1. Log in to Bamboo as a user with ‘Admin’ permission.
2. In the Bamboo administration area click User Directories (under “Security”).
3. Click Add Directory and select Atlassian JIRA.
4. Enter settings, as described below.
5. Test and save the directory settings.
6. Define the directory order, on the 'User Directories' screen, by clicking the arrows for each directory. The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
3. Set up Bamboo users and groups in JIRA Software

In order to use Bamboo, users must be a member of the Bamboo-users group or have Bamboo global permissions. Follow these steps to configure your Bamboo groups in JIRA Software:

1. Add the bamboo-users and bamboo-administrators groups in JIRA Software.
2. Add your own username as a member of both of the above groups.
3. Choose one of the following methods to give your existing JIRA Software users access to Bamboo:
   - Option 1: In JIRA Software, find the groups that the relevant users belong to. Add those groups as members of one or both of the above Bamboo groups.
   - Option 2: Log in to Bamboo using your JIRA Software account and go to the administration area. Click Global permissions (under 'Security'). Assign the appropriate permissions to the relevant JIRA Software groups. See Global permissions.

Connecting Atlassian Bamboo to JIRA Software for user management is not sufficient, by itself, to allow your users to log in to Bamboo. You must also grant them access to Bamboo by using one of the above 2 options.

We recommend that you use groups instead of individual accounts when granting permissions.

Connecting Bamboo to JIRA for user management v6.6

⚠️ This page does not apply to JIRA Software Cloud; you can’t use JIRA Software Cloud to manage your Bamboo users.

You can connect Bamboo to an existing Atlassian JIRA Software instance to delegate Bamboo user and group management, and
authentication. Bamboo provides a "read-only" connection to JIRA Software for user management. This means that users and groups, fetched from JIRA Software, can only be modified or updated in that JIRA Software server, rather than in Bamboo.

Choose this option, as an alternative to Atlassian Crowd, for simple configurations with a limited number of users. Note that Bamboo can only connect to an instance running JIRA Software 4.3 or later.

Connecting Bamboo and JIRA Software is a 3-step process:

1. Set up JIRA Software to allow connections from Bamboo
2. Set up Bamboo to connect to JIRA Software
3. Set up Bamboo users and groups in JIRA Software

Also on this page:
- Server settings
- JIRA Software server permissions
- Advanced settings

⚠️ You need to be an administrator in JIRA Software and a system administrator in Bamboo to perform the following tasks.

1. Setup JIRA Software to allow connections from Bamboo
   1. Log in as a user with the 'JIRA Software Administrators' global permission.
   2. For JIRA 4.3.x, select Other Application from the 'Users, Groups & Roles' section of the 'Administration' menu.
      For later versions, choose Administration > Users > JIRA User Server.
   3. Click Add Application.
   4. Enter the application name (case-sensitive) and password that Bamboo will use when accessing JIRA Software.
   5. Enter the IP address of your Bamboo instance. Valid values are:
      - A full IP address, e.g. 192.168.10.12.
      - A wildcard IP range, using CIDR notation, e.g. 192.168.10.1/16. For more information, see the introduction to CIDR notation on Wikipedia.
   6. Click Save.
   7. Define the directory order, on the 'User Directories' screen, by clicking the blue up- and down-arrows next to each directory.

2. Setup Bamboo to connect to JIRA Software
   1. Log in to Bamboo as a user with 'Admin' permission.
   2. In the Bamboo administration area click User Directories (under 'Security').
   3. Click Add Directory and select Atlassian JIRA.
   4. Enter settings, as described below.
   5. Test and save the directory settings.
   6. Define the directory order, on the 'User Directories' screen, by clicking the arrows for each directory.

3. Set up Bamboo users and groups in JIRA Software
   In order to use Bamboo, users must be a member of the Bamboo-users group or have Bamboo global permissions. Follow these steps to configure your Bamboo groups in JIRA Software:
   1. Add the bamboo-users and bamboo-administrators groups in JIRA Software.
   2. Add your own username as a member of both of the above groups.
   3. Choose one of the following methods to give your existing JIRA Software users access to Bamboo:
      - Option 1: In JIRA Software, find the groups that the relevant users belong to. Add those groups as members of one or both of the above Bamboo groups.
      - Option 2: Log in to Bamboo using your JIRA Software account and go to the administration area. Click Global permissions (under 'Security'). Assign the appropriate permissions to the relevant JIRA Software Groups. See Global permissions.

Connecting Atlassian Bamboo to JIRA Software for user management is not sufficient, by itself, to allow your users to log in to Bamboo. You must also grant them access to Bamboo by using one of the above 2 options.

We recommend that you use groups instead of individual accounts when granting permissions.

### Managing permissions

#### Controlling access to build plans

You can use global permissions to control the users and groups that have access to build plans, and the actions they can perform.

Common global permissions tasks are:

- **Granting plan permissions in bulk** — control the users and groups that can perform actions on plans (e.g. edit, build, clone).
- **Granting global permissions to users or groups** — control the users and groups that can create plans, delete plans, and administer Bamboo.
- **Allowing anonymous access to Bamboo** — allow people not logged in to Bamboo to generate reports, and view plans and build results.

You can also change the permissions for an individual plan: see [Configuring a plan's permissions](#).

#### Controlling access to the Bamboo server

Global security and permission properties allow a Bamboo system administrator to configure security- and permission-related properties that apply to Bamboo at a site-wide level.

Read more about configuring Bamboo's global security and permission properties:

- **Allowing public signup**
- **Displaying full details about users**
- **Using Captcha for failed logins**
Granting plan permissions in bulk

A plan permission is the ability to perform a particular operation on a plan and its jobs. For each plan, different permissions can be granted to particular groups and/or users.

- People who have the 'Admin' global permission can 'bulk edit' permissions for multiple plans at the same time, as described below.
  
  Note that this will overwrite any pre-existing plan permissions.

- People who have the 'Admin' plan permission for one or more plans, but do not have the 'Admin' global permission, can only edit one plan at a time, as described in Configuring a plan's permissions.

Note that it is recommended that you grant permissions to groups rather than to individual users.

**To grant bulk plan permissions to a user or group:**

1. Click the
   
   icon in the Bamboo header and choose Overview.

2. In the Plans section of left navigation panel, click Bulk Edit Plan Permissions.

3. Select the plans whose permissions you wish to edit, then click Next (at the bottom of the screen).

4. You can set plan permissions for the categories of users in the table below.

5. Select the check box for each permission that you wish to grant to the user or group.

6. Click Save.

**Logged in Users**

Users who are logged in to Bamboo.

**Anonymous Users**

Users who are not logged in to Bamboo.

**User**

A user already created in the Bamboo system.

To edit plan permissions for an existing user:

1. In the Grant permission to list, select User.
2. Type the username into the box, or click the icon to select from a list.
3. Click Add. The user will be added to the list on the screen, and you can then select permissions for them.

**Group**

A group already created in the Bamboo system.

To edit plan permissions for an existing group:

1. In the Grant permission to list, select Group.
2. Type the group name into the box.
3. Click Add. The group will be added to the list on the screen, and you can then select permissions for the group.

*Screenshot: Bulk Edit Plan Permissions Wizard*
Granting plan permissions in bulk v5.14

A plan permission is the ability to perform a particular operation on a plan and its jobs. For each plan, different permissions can be granted to particular groups and/or users.

- People who have the 'Admin' global permission can 'bulk edit' permissions for multiple plans at the same time, as described below. Note that this will overwrite any pre-existing plan permissions.
- People who have the 'Admin' plan permission for one or more plans, but do not have the 'Admin' global permission, can only edit one plan at a time, as described in Configuring a plan's permissions.

Note that it is recommended that you grant permissions to groups rather than to individual users.

To grant bulk plan permissions to a user or group:

1. Click the icon in the Bamboo header and choose Overview.
2. In the Plans section of left navigation panel, click Bulk Edit Plan Permissions.
3. Select the plans whose permissions you wish to edit, then click Next (at the bottom of the screen).
4. You can set plan permissions for the categories of users in the table below.
5. Select the check box for each permission that you wish to grant to the user or group.
6. Click Save.

- **Clone Admin** - User can administrate all components of this plan, including the stages and the plan's permissions.

**Note:**
Users with the global 'admin' permission have all of the above permissions for this plan.

Granting plan permissions in bulk v6.1

A **plan permission** is the ability to perform a particular operation on a **plan** and its **jobs**. For each plan, different permissions can be granted to particular groups and/or users.

- People who have the 'Admin' global permission can 'bulk edit' permissions for multiple plans at the same time, as described below. Note that this will overwrite any pre-existing plan permissions.
- People who have the 'Admin' plan permission for one or more plans, but do not have the 'Admin' global permission, can only edit one plan at a time, as described in Configuring a plan's permissions.

Note that it is recommended that you grant permissions to groups rather than to individual users.

To grant bulk plan permissions to a user or group:

1. Click the
1. Click the gear icon in the Bamboo header and choose Overview.
2. In the Plans section of left navigation panel, click Bulk Edit Plan Permissions.
3. Select the plans whose permissions you wish to edit, then click Next (at the bottom of the screen).
4. You can set plan permissions for the categories of users in the table below.
5. Select the check box for each permission that you wish to grant to the user or group.
6. Click Save.

Logged in Users
Users who are logged in to Bamboo.

Anonymous Users
Users who are not logged in to Bamboo.

User
A user already created in the Bamboo system.

To edit plan permissions for an existing user:
1. In the Grant permission to list, select User.
2. Type the username into the box, or click the icon to select from a list.
3. Click Add. The user will be added to the list on the screen, and you can then select permissions for them.

Group
A group already created in the Bamboo system.

To edit plan permissions for an existing group:
1. In the Grant permission to list, select Group.
2. Type the group name into the box.
3. Click Add. The group will be added to the list on the screen, and you can then select permissions for the group.

Screenshot: Bulk Edit Plan Permissions Wizard

Granting global permissions to users or groups
Global permissions control which users and groups have access to build plans and the Bamboo server, and what actions they can perform.

Note that if you remove all permissions for a user or group, that user or group will disappear from the Permissions tab for all plans.
To change global permissions:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Global Permissions in the left navigation panel, and then Edit Global Permissions.
3. You can set plan permissions for the categories of users in the table below.
4. Select (or clear) the check box for each permission that you wish to change for a user or group.
5. Click Save.

Logged in Users
Users who are logged in to Bamboo.

Anonymous Users
Users who are not logged in to Bamboo.

User
A user already created in the Bamboo system.

To edit plan permissions for an existing user:

1. In the Grant permission to list, select User.
2. Type the username into the box, or click the icon to select from a list.
3. Click Add. The user will be added to the list on the screen, and you can then select permissions for them.

Group
A group already created in the Bamboo system.

To edit plan permissions for an existing group:

1. In the Grant permission to list, select Group.
2. Type the group name into the box.
3. Click Add. The group will be added to the list on the screen, and you can then select permissions for the group.

You can grant the following global permissions:

<table>
<thead>
<tr>
<th>Global permission</th>
<th>Description</th>
<th>Can be granted to</th>
</tr>
</thead>
</table>
| **Access**        | Permission to view the Bamboo system. The ability to view build plans and build results is **subject to individual plan permissions**. | • a particular user  
• a particular group  
• all logged-in users  
• anonymous users |
| **Create Plan**   | Permission to:  
• create new build plans  
• configure linked repositories | • a particular user  
• a particular group  
• all logged-in users |
| **Create repository** | Permission to:  
• create new repositories | • a particular user  
• a particular group |

Only users with Admin permissions on the global level can create repositories by default. Plan administrators can only select from linked repositories or must be granted the Create repository permission explicitly. See also: plan permissions.
Global permissions

You can edit your global application level permissions here. Permissions can be granted to specific users or groups. Please note these are global application permissions. For plan level permissions, please go to the plan configuration page.

Screenshot: Global Permissions

.Granting global permissions to users or groups v5.14

Global permissions control which users and groups have access to build plans and the Bamboo server, and what actions they can perform.

Note that if you remove all permissions for a user or group, that user or group will disappear from the Permissions tab for all plans.

Related pages:

- Configuring a plan’s permissions
- Managing users

To change global permissions:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Global Permissions in the left navigation panel, and then Edit Global Permissions.
3. You can set plan permissions for the categories of users in the table below.
4. Select (or clear) the check box for each permission that you wish to change for a user or group.
5. Click Save.

Logged in Users
Users who are logged in to Bamboo.

Anonymous Users
Users who are not logged in to Bamboo.

User
A user already created in the Bamboo system.

To edit plan permissions for an existing user:

1. In the Grant permission to list, select User.
2. Type the username into the box, or click the icon to select from a list.
3. Click Add. The user will be added to the list on the screen, and you can then select permissions for them.
**Group**
A group already created in the Bamboo system.

To edit plan permissions for an existing group:

1. In the **Grant permission to** list, select **Group**.
2. Type the group name into the box.
3. Click **Add**. The group will be added to the list on the screen, and you can then select permissions for the group.

You can grant the following global permissions:

<table>
<thead>
<tr>
<th>Global permission</th>
<th>Description</th>
<th>Can be granted to</th>
</tr>
</thead>
</table>
| **Access**        | Permission to view the Bamboo system. The ability to view build plans and build results is subject to individual **plan permissions**. | • a particular user  
                    • a particular group  
                    • all logged-in users  
                    • anonymous users |
| **Create Plan**   | Permission to:  
                    • create new build plans  
                    • configure linked repositories | • a particular user  
                    • a particular group  
                    • all logged-in users |
| **Create repository** | Permission to:  
                     • create new repositories | • a particular user  
                      • a particular group |
| **Admin**         | Permission to:  
                    • access the Bamboo Administration menu  
                    • create plans  
                    • delete plans  
                    • configure linked repositories  
                    The 'Admin' global permission also includes all **plan permissions**, for every plan. | • a particular user  
                    • a particular group |

*Screenshot: Global Permissions*
Global permissions

You can edit your global application level permissions here. Permissions can be granted to specific users or groups. Please note these are global application permissions. For plan level permissions, please go to the plan configuration page.

<table>
<thead>
<tr>
<th>Groups</th>
<th>Access</th>
<th>Create plan</th>

<td>✔</td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Anonymous users</td>
<td>✔</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Click the icon in the Bamboo header and choose Overview.

1. Click Global permissions (under Security), and then Edit Global Permissions.
2. Check in the Access column for 'Anonymous users'.
3. Click Save.

Anonymous users will now be able to access your Bamboo system. However, they will only be able to view plans and build results for plans where the 'Access' plan permission has been granted to 'Anonymous users'.

Allowing anonymous access to Bamboo

Allowing anonymous users to access your Bamboo system means that people who aren’t logged in to Bamboo will be able to perform functions such as generating reports, and viewing plans and build results — subject to individual plan permissions.

Note that people who aren’t logged in to Bamboo do not have a 'My Bamboo' tab on their Dashboard.

To allow anonymous users to access Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Global permissions (under Security), and then Edit Global Permissions.
3. Check in the Access column for 'Anonymous users'.
4. Click Save.

Anonymous users will now be able to access your Bamboo system. However, they will only be able to view plans and build results for plans where the 'Access' plan permission has been granted to 'Anonymous users'.

Allowing anonymous access to Bamboo v5.14

Allowing anonymous users to access your Bamboo system means that people who aren’t logged in to Bamboo will be able to perform functions such as generating reports, and viewing plans and build results — subject to individual plan permissions.

Note that people who aren’t logged in to Bamboo do not have a 'My Bamboo' tab on their Dashboard.

To allow anonymous users to access Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Global permissions (under Security), and then Edit Global Permissions.
3. Check in the Access column for 'Anonymous users'.
4. Click Save.

Anonymous users will now be able to access your Bamboo system. However, they will only be able to view plans and build results for plans where the 'Access' plan permission has been granted to 'Anonymous users'.

Allowing anonymous access to Bamboo v6.4

Allowing anonymous users to access your Bamboo system means that people who aren’t logged in to Bamboo will be able to perform functions such as generating reports, and viewing plans and build results — subject to individual plan permissions.

Note that people who aren’t logged in to Bamboo do not have a 'My Bamboo' tab on their Dashboard.
To allow anonymous users to access Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Global permissions (under "Security").

Anonymous users will now be able to access your Bamboo system. However, they will only be able to view plans and build results for plans where the ‘Access’ plan permission has been granted to ‘Anonymous users’.

Allowing public signup

If you enable signup for your Bamboo system, visitors can create their own Bamboo user accounts. Public signup is enabled on your Bamboo site if you see the 'Signup' link at the top-right of the Bamboo user interface.

To enable (or disable) signup:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Security Settings (under 'Security') in the left navigation panel to open the 'Global Security and Permission Properties' page.
3. Click Edit on this page.
4. Select, (or clear) the Enable Signup? check box.
5. Select Enable Captcha On Signup if you require an additional security measure to prevent brute force attacks.
6. Click Save.
7. Log out of Bamboo and verify that the top menu bar now contains (or does not contain) a Signup link.
Displaying full details about users

If you enable the display of contact details on your Bamboo system, the full contact details for all users, including email address, IM address, and group membership, will be visible to any visitors to Bamboo. The email addresses of administrators on the 'Contact Administrators' page will also be visible.

To enable (or disable) the display of contact details:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Security Settings (under 'Security') in the left navigation panel to open the 'Global Security and Permission Properties' page.
3. Click Edit on this page.
4. Select (or clear) the Enable contact details to be displayed? check box.
5. Click Save.

Using Captcha for failed logins

Captcha is a tool that prevents brute force attacks on the Bamboo login screen. A brute force attack occurs when an attacker uses malicious code to make automated, repeated login attempts on a Bamboo site with the aim of gaining access to that Bamboo site.

A Bamboo system administrator can configure Bamboo to block automated login attempts. Once a certain number of failed login attempts has been reached (the default is three) Bamboo's Captcha feature will be activated. When Captcha is activated, users will need to recognize a distorted picture of a word and must type the word into a text field. This is easy for humans to do, but very difficult for computers.

To enable (or disable) Captcha for Bamboo:
1. Click the icon in the Bamboo header and choose **Overview**.
2. Click **Security Settings** (under 'Security') in the left navigation panel to open the 'Global Security and Permission Properties' page.
3. Click **Edit** on this page.
4. Select (or clear) the **Enable Captcha** check box.
5. If required, specify the number of failed login attempts permitted by Bamboo before Captcha is activated. (This field is mandatory and requires a value of 1 or more.)
6. Click **Save**.

### Managing authors

An *author* is any person who contributes to a build by checking-in code to a repository that is associated with a Bamboo plan. Bamboo extracts the author name from the code repository; an author need not be a Bamboo user.

Bamboo allows you to associate an author with a user. Association is with either the username or email address, and can be automatically or manually configured. This is useful for identifying who has made a particular commit, providing system notifications and apportioning blame. Author association also allows a user to quickly identify their commits on the MyBamboo tab.

**On this page:**
- To manage Bamboo authors
- To associate an author with a user
- To disassociate an author with a user

**Related pages:**
- Managing permissions
- Associating your author name with your user profile

**To manage Bamboo authors**

1. Click the icon in the Bamboo header and choose **Overview**.
2. Select Authors from the side panel. The Manage Authors screen will display:
3. On the 'Manage Authors' page you can perform any of the following actions:

**Search for author**
Search for a particular author using their repository author name

**Search for user**
Search for a particular author by their linked user name to see their author association

**Link user**
Link an author with their Bamboo user

**Unlink user**
Unlink an author from their Bamboo user

**Unlink all authors**
Remove all existing author and user associations

**Auto-link unlinked authors**
Automatically associate any unlinked authors with a Bamboo user based on their Bamboo username or Email address

To associate an author with a user

1. From the Manage Authors screen, use the search tool to locate the author in question
2. Select the unlinked author and click **Link with user**
3. Enter the user's name in the field, or use the drop down menu to select a user:

![Link with user](image)

4. Click **Add**

**Note:** You can link more than one author name to a Bamboo user name.

To disassociate an author with a user

1. From the Manage Authors screen, use the search tool to locate the author or username in question
2. Click **Unlink user**

An **author** is any person who contributes to a **build** by checking-in code to a repository that is associated with a Bamboo **plan**. Bamboo
extracts the author name from the code repository; an author need not be a Bamboo user.

Bamboo allows you to associate an author with a user. Association is with either the username or email address, and can be automatically or manually configured. This is useful for identifying who has made a particular commit, providing system notifications and apportioning blame. Author association also allows a user to quickly identify their commits on the MyBamboo tab.

To manage Bamboo authors

1. Click the icon in the Bamboo header and choose Overview.

2. Select Authors from the side panel. The Manage Authors screen will display:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search for author</td>
<td>Search for a particular author using their repository author name</td>
</tr>
<tr>
<td>Search for user</td>
<td>Search for a particular author by their linked user name to see their author association</td>
</tr>
<tr>
<td>Link user</td>
<td>Link an author with their Bamboo user</td>
</tr>
<tr>
<td>Unlink user</td>
<td>Unlink an author from their Bamboo user</td>
</tr>
<tr>
<td>Unlink all authors</td>
<td>Remove all existing author and user associations</td>
</tr>
<tr>
<td>Auto-link unlinked authors</td>
<td>Automatically associate any unlinked authors with a Bamboo user based on their Bamboo username or Email address</td>
</tr>
</tbody>
</table>

To associate an author with a user

1. From the Manage Authors screen, use the search tool to locate the author in question
2. Select the unlinked author and click Link with user
3. Enter the user’s name in the field, or use the drop down menu to select a user:

<table>
<thead>
<tr>
<th>Username</th>
</tr>
</thead>
<tbody>
<tr>
<td>User1</td>
</tr>
<tr>
<td>User2</td>
</tr>
<tr>
<td>User3</td>
</tr>
</tbody>
</table>

4. Click **Add**

**Note:** You can link more than one author name to a Bamboo user name.

To disassociate an author with a user

1. From the Manage Authors screen, use the search tool to locate the author or username in question.
2. Click **Unlink user**

Managing authors v6.1

An author is any person who contributes to a build by checking-in code to a repository that is associated with a Bamboo plan. Bamboo extracts the author name from the code repository; an author need not be a Bamboo user.

Bamboo allows you to associate an author with a user. Association is with either the username or email address, and can be automatically or manually configured. This is useful for identifying who has made a particular commit, providing system notifications and apportioning blame. Author association also allows a user to quickly identify their commits on the MyBamboo tab.

To manage Bamboo authors

1. Click the ![icon](image)

icon in the Bamboo header and choose **Overview**.

2. Select Authors from the side panel. The Manage Authors screen will display:
3. On the 'Manage Authors' page you can perform any of the following actions:

**Search for author**
Search for a particular author using their repository author name

**Search for user**
Search for a particular author by their linked user name to see their author association

**Link user**
Link an author with their Bamboo user

**Unlink user**
Unlink an author from their Bamboo user

**Unlink all authors**
Remove all existing author and user associations

**Auto-link unlinked authors**
Automatically associate any unlinked authors with a Bamboo user based on their Bamboo username or Email address

**To associate an author with a user**
1. From the Manage Authors screen, use the search tool to locate the author in question
2. Select the unlinked author and click **Link with user**
3. Enter the user's name in the field, or use the drop down menu to select a user:

   ![Link with user](image)

   **Username**
   - Dre Kencelte (akerroide)
   - Dave Cook (dacook)
   - Daniel Johnson (djohnson)
   - Diego Alonso (dalonso)
   - Duc Dao (darhdao)

   **Add**

4. Click **Add**

   **Note:** You can link more than one author name to a Bamboo user name.

**To disassociate an author with a user**

1. From the Manage Authors screen, use the search tool to locate the author or username in question
2. Click **Unlink user**

**Users and permissions v6.1**

There are several options for managing your Bamboo users and groups:
• Manage locally in Bamboo
• Manage with Atlassian's Jira applications or Crowd
• Manage with an external user repository, such as LDAP.

On this page:

• Choose a user management option
• About users and authors
• About groups
• Bamboo permissions

Note that the information on this page does not relate to application-level security for Bamboo — see Security instead.

Choose a user management option

To choose how you want to manage users in Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. Navigate to User repositories (under ‘Security’).
3. Choose one of the user management options:

   Manage locally in Bamboo
   Managing users
   Managing groups

   Manage with Atlassian's Jira applications
   Allowing Other Applications to Connect to Jira applications for User Management

   Manage with Atlassian's Crowd
   Integrating Bamboo with Crowd

   Manage in a custom external user directory
   Integrating Bamboo with LDAP
4. Click Save.

About users and authors

An author is any person who checks in code to a repository that is associated with a Bamboo plan. An author need not be a Bamboo user.

Depending on your organization’s requirements, you can configure Bamboo to grant access to non-users. However, only Bamboo users can:

• view the My Bamboo tab on the Dashboard.
• belong to a group.

About groups

Bamboo groups are used to specify which users will have global permissions and plan permissions. They can also be used to specify which users will receive notifications about a plan’s build results. You can create and delete as many groups as you need. You will typically create at least one group per project.

A special group called bamboo-admin is automatically created when you install Bamboo. Members of this group have Bamboo administration rights.

Bamboo permissions

Bamboo permissions control access to plans, builds and administration functions. See Managing permissions.

A plan permission is the ability to perform a particular operation on a plan and its jobs. For each plan, different permissions can be granted to particular groups and/or users. A global permission is the ability to perform a particular operation in relation to Bamboo as a whole.

Users and permissions v5.14

There are several options for managing your Bamboo users and groups:

• Manage locally in Bamboo
• Manage with Atlassian's Jira applications or Crowd
• Manage with an external user repository, such as LDAP.
Choose a user management option

To choose how you want to manage users in Bamboo:

1. Click the icon in the Bamboo header and choose Overview.
2. Navigate to User repositories (under ‘Security’).
3. Choose one of the user management options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manage locally in Bamboo</td>
<td>Managing users</td>
</tr>
<tr>
<td>Manage with Atlassian's Jira applications</td>
<td>Allowing Other Applications to Connect to Jira applications for User Management</td>
</tr>
<tr>
<td>Manage with Atlassian's Crowd</td>
<td>Integrating Bamboo with Crowd</td>
</tr>
<tr>
<td>Manage in a custom external user directory</td>
<td>Integrating Bamboo with LDAP</td>
</tr>
</tbody>
</table>

4. Click Save.

About users and authors

An author is any person who checks in code to a repository that is associated with a Bamboo plan. An author need not be a Bamboo user. Depending on your organization’s requirements, you can configure Bamboo to grant access to non-users. However, only Bamboo users can:

- view the My Bamboo tab on the Dashboard.
- belong to a group.

About groups

Bamboo groups are used to specify which users will have global permissions and plan permissions. They can also be used to specify which users will receive notifications about a plan's build results. You can create and delete as many groups as you need. You will typically create at least one group per project.

A special group called bamboo-admin is automatically created when you install Bamboo. Members of this group have Bamboo administration rights.

Bamboo permissions

Bamboo permissions control access to plans, builds and administration functions. See Managing permissions.

A plan permission is the ability to perform a particular operation on a plan and its jobs. For each plan, different permissions can be granted to particular groups and/or users. A global permission is the ability to perform a particular operation in relation to Bamboo as a whole.

Connecting Bamboo to an external database

Bamboo can be connected to an external database. For details and instructions please see:

- PostgreSQL
- MySQL
  - Tomcat and External MySQL Datasource Example
- Oracle
- Microsoft SQL Server
  - Transitioning from jTDS to Microsoft's JDBC driver
- Viewing your database connection details
- Moving your Bamboo data to a different database
Troubleshooting Databases

PostgreSQL
This page describes how to connect Bamboo to a PostgreSQL database.
Note that the JDBC driver for PostgreSQL is bundled with Bamboo. You do not have to download and install the driver.
See Supported platforms for other information about the versions of PostgreSQL supported by Bamboo.

On this page:
1. Configuring PostgreSQL
2. Connecting Bamboo to PostgreSQL

Related pages:
- Troubleshooting Databases

1. Configuring PostgreSQL

Accept remote TCP connections (remote PostgreSQL server only)
If you are connecting Bamboo to a remote PostgreSQL server (i.e. if your PostgreSQL server is not installed locally on your Bamboo server host system), you will need to configure your data/postgresql.conf and data/pg_hba.conf files to accept remote TCP connections from your Bamboo server's IP address.

The following PostgreSQL documentation contains information on the appropriate listen_addresses value in the postgresql.conf file as well as the pg_hba.conf file:
- PostgreSQL 8.2 documentation — Connections and Authentication

Once you have modified your data/postgresql.conf and data/pg_hba.conf files, you will need to restart PostgreSQL for your changes to take effect.

Creating a Bamboo database

```
sudo -s -H -u postgres
# Create the Bamboo user:
/opt/PostgreSQL/8.3/bin/createuser -S -d -r -P bamboouser
# Create the bamboo database:
/opt/PostgreSQL/8.3/bin/createdb -O bamboouser bamboo
exit
```

Creating a completely empty Bamboo database is recommended. Avoid using templates to create the database as some may insert default tables which can lead to conflicts when setting up Bamboo.

2. Connecting Bamboo to PostgreSQL

Bamboo provides two ways to connect to a PostgreSQL database — using JDBC or using a datasource. JDBC is generally simpler and is the recommended method.

Run the Setup wizard

For both methods, run the Setup Wizard and choose the Custom Installation option.

On the 'Choose a Database Configuration' page, choose External Database, select PostgreSQL 8.2 and above from the list and click Continue.

Choose one of the following:

Connecting using JDBC

On the 'Database Configuration' page of the Setup Wizard, ensure that Direct JDBC connection has been selected and make the following settings:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
</table>

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Driver Class Name: Type `org.postgresql.Driver` (if different from the default).

Driver Class Name: Type the URL where Bamboo will access your database (if different from the default). For details about syntax, please refer to the Postgres JDBC driver documentation.

User Name: Type the username that Bamboo will use to access your database.

Password: Type the password (if required) that Bamboo will use to access your database.

Overwrite existing data: Select if you wish Bamboo to overwrite any tables that already exist in the database.

**Screenshot 1: Setup JDBC Connection (PostgreSQL)**

**Database Configuration**

Choose how you wish Bamboo to connect to your database

**Select Database Connection**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JNDI name</td>
<td>Type the JNDI name of your datasource, as configured in your application server.</td>
</tr>
<tr>
<td>Overwrite existing data</td>
<td>Select if you wish Bamboo to overwrite any tables that already exist in the database.</td>
</tr>
</tbody>
</table>

Connecting with a datasource

Configure a datasource in your application server (consult your application server documentation for details).

For details about the syntax to use for the JDBC database URL, please see the Postgres JDBC driver documentation.

On the 'Database Configuration' page of the Setup Wizard, choose **Connect via a datasource (configured in the application server)** and make the following settings:

**Screenshot 2: Setup Datasource Connection**
This page describes how to connect Bamboo to a MySQL database.

On this page:

Troubleshooting Databases

MySQL
This page describes how to connect Bamboo to a MySQL database.

On this page:
1. Creating and Configuring the MySQL database
2. Connecting Bamboo to the MySQL database
   Connect using JDBC
   Connect using a datasource

1. Creating and Configuring the MySQL database

To connect Bamboo to an external MySQL database, you must first create and configure it. This database must be configured to use:

- utf8 character set encoding, instead of latin1
- utf8_bin collation
- the InnoDB storage engine
- (recommended, not required) lower_case_table_names=1

Setting lower_case_table_names=1 might break other Atlassian applications. For more information, see the steps.

- global transaction isolation level as READ_COMMITTED

If your MySQL database server is configured to use a storage engine other than InnoDB by default (such as MyISAM), then if possible change it to use InnoDB. Otherwise, you can configure Bamboo's JDBC connection to your MySQL database so that any tables which Bamboo creates in this database will be data in using the InnoDB database engine.

A MySQL database administrator can easily create and configure a MySQL database for Bamboo by running the following MySQL commands:

```sql
mysql> CREATE DATABASE bamboo CHARACTER SET utf8 COLLATE utf8_bin;
mysql> GRANT ALL PRIVILEGES ON bamboo.* TO 'bamboouser'@'localhost'
    IDENTIFIED BY 'password';
mysql> FLUSH PRIVILEGES;
mysql> QUIT
```
This creates an empty MySQL database for Bamboo named bamboo, where:

- **bamboouser** — the user account name for the Bamboo MySQL database
- **localhost** — the host name of the MySQL database server
- **password** — the password for this user account

With Bamboo 5.14, we’re dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13

See See Bamboo 5.13 Release Notes

However, we still recommend setting `lower_case_table_names=1`

**Important**

Changing the value of the `lower_case_table_names` parameter requires an export/import of all MySQL databases, and might affect functionality of other applications that use the same MySQL installation.

To change the value of the `lower_case_table_names` parameter:

1. Create a database dump for every database in your MySQL server:

```bash
mysql -u <username> -p <password> <dbname> <path_to_dump_file>
```

2. Use DROP DATABASE to drop the database that you’re recreating.
3. Stop your MySQL DB system. You must stop all applications that are using the MySQL instance.
5. Restart the MySQL service.
6. Reload the `mysqldump` for each database to convert the database and table names to lowercase:

```bash
mysql < db1.sql
mysql < db2.sql
```

More information can be found in the MySQL documentation.

For more information about configuring character set encoding and collation for Bamboo MySQL databases, refer to the MySQL 5 documentation — Specifying Character Sets and Collations.

2. Connecting Bamboo to the MySQL database

Bamboo provides two ways to connect to a MySQL database — by using either JDBC or a datasource. JDBC is generally simpler and is the recommended method.

**Connect using JDBC**

1. **Download and install the JDBC driver**

   The JDBC drivers for MySQL Enterprise Server are no longer bundled with Bamboo (due to licensing restrictions). You need to download and install the driver yourself.

   1. Download the MySQL Connector/J JDBC driver from the download site.
   2. Expand the downloaded zip/tar.gz file.
   3. Copy the `mysql-connector-java-5.XX-bin.jar` file from the extracted directory to the `<Bamboo installation directory>/lib` directory. (create the lib/ directory if it doesn't already exist). If you are using the Java Service Wrapper to start your Bamboo instance (Bamboo/wrapper/run-bamboo start), copy the `mysql-connector-java-5.XX-bin.jar` file to `<Bamboo installation directory>/wrapper/lib` directory.
   4. Stop Bamboo, on Windows, Linux or Mac.
   5. Restart Bamboo, on Windows, Linux or Mac.

2. **Connect Bamboo to a MySQL database using JDBC**

   1. Run the Setup Wizard and choose the Custom Installation method.
   2. On the 'Choose a Database Configuration' page, choose External Database > MySQL 5.1 and click Continue.
   3. Ensure that Direct JDBC connection is selected and complete the following fields (as shown in the screenshot below):
**Driver Class Name**  
Type `com.mysql.jdbc.Driver` (if different from the default).

**Database URL**  
Type the URL where Bamboo will access your database (if different from the default). Your URL must include the `autoReconnect=true` flag.  
- If you intend to use non-Latin characters in Bamboo, ensure that your URL includes the `useUnicode=true` and `characterEncoding=utf8` flags.  
- If your MySQL database server is configured to use a storage engine other than InnoDB by default, ensure that your URL includes the sessionVariables=storage_engine=InnoDB flag.  
If you include all of these flags, your Database URL should look similar to:  
```
jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8&sessionVariables=storage_engine=InnoDB
```

**User Name**  
Type the username that Bamboo will use to access your database. This is `bamboouser` defined in section 1 (above).

**Password**  
Type the password (if required) that Bamboo will use to access your database. This is `password` defined in section 1 (above). Leave this field blank if a password for the database user account was not specified.

4. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
5. Click **Continue**.

---

**Screenshot: Setup JDBC Connection (MySQL)**

---

**Database Configuration**  
Choose how you wish Bamboo to connect to your database

**Select Database Connection**

- Direct JDBC connection
- Connect via a datasource (configured in the application server)

**Driver Class Name:**  
`com.mysql.jdbc.Driver`  
The class name of the database driver. Ensure that this class is in your class path.

**Database URL:**  
`jdbc:mysql://localhost/bamboo?autoReconnect=true`  
The URL to access the database.

**User Name:**  
The username to access the database.

**Password:**  
(Optional) Enter the password if the database configuration requires it.

**Overwrite existing data**  
If you wish Bamboo to overwrite any existing tables that may exist in the database.
Connect using a datasource

1. Configure a datasource in your application server (consult your application server documentation for details). Please note the following:
   - Ensure that the JDBC URL which you configure in your application server includes the `autoReconnect=true`, `useUnicode=true`, and `characterEncoding=utf8` flags, such that your database URL should look similar to: `jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8`
   - If your MySQL database server is configured to use a storage engine other than InnoDB by default, also include the `storage_engine=InnoDB` flag in this URL.
   - If the autoReconnect flag is not set, the MySQL JDBC driver will eventually time out and Bamboo will no longer be able to communicate with the database.
   - Datasource example: You can see an example of using Tomcat with a MySQL database as a datasource in the following document: Tomcat and External MySQL Datasource Example.

2. Run the Setup Wizard and choose the Custom Installation method.
3. Choose External Database > MySQL 5.1 from the list and click Continue.
4. Choose Connect via a datasource (configured in the application server) (as shown in the screenshot below).
5. In the JNDI name field, type the JNDI name of your datasource, as configured in your application server.
6. Select Overwrite existing data if you wish Bamboo to overwrite any tables that already exist in the database.
7. Click Continue.

Screenshot 2: Setup Datasource Connection

**Database Configuration**

Choose how you wish Bamboo to connect to your database

**Select Database Connection**

- [ ] Direct JDBC connection
- [x] Connect via a datasource (configured in the application server)

**JNDI name:**

If `java:comp/env/jdbc/DataSourceName` does not work, try `jdbc/DataSourceName` (or vice versa).

**Overwrite existing data**

If you wish Bamboo to overwrite any existing tables that may exist in the database.

Click **Continue**

**Tomcat and External MySQL Datasource Example**

Add the DataSource Resource tag inside the Context tags of your context descriptor in the server.xml file located under `<bamboo-installation-directory>/conf`:

```xml
<Context .... >
<Resource name="jdbc/bamboo" auth="Container" type="javax.sql.DataSource"
    username="yourusername"
    password="yourpassword"
    driverClassName="com.mysql.jdbc.Driver"
    url="jdbc:mysql://localhost:3306/bamboo?autoReconnect=true"
    maxActive="100"
    maxIdle="7"
    validationQuery="Select 1" />
</Context>
```

**MySQL v5.14**

This page describes how to connect Bamboo to a MySQL database.
1. Creating and Configuring the MySQL database

To connect Bamboo to an external MySQL database, you must first create and configure it. This database must be configured to use:

- utf8 character set encoding, instead of latin1
- utf8_bin collation
- the InnoDB storage engine
- (recommended, not required) lower_case_table_names=1

Setting lower_case_table_names=1 might break other Atlassian applications. For more information, see the steps.

- global transaction isolation level as READ_COMMITTED

If your MySQL database server is configured to use a storage engine other than InnoDB by default (such as MyISAM), then if possible change it to use InnoDB. Otherwise, you can configure Bamboo’s JDBC connection to your MySQL database so that any tables which Bamboo creates in this database will be done using the InnoDB database engine.

A MySQL database administrator can easily create and configure a MySQL database for Bamboo by running the following MySQL commands:

```
mysql> CREATE DATABASE bamboo CHARACTER SET utf8 COLLATE utf8_bin;
mysql> GRANT ALL PRIVILEGES ON bamboo.* TO 'bamboouser'@'localhost'
    IDENTIFIED BY 'password';
mysql> FLUSH PRIVILEGES;
mysql> QUIT
```

This creates an empty MySQL database for Bamboo named bamboo, where:

- bamboouser — the user account name for the Bamboo MySQL database
- localhost — the host name of the MySQL database server
- password — the password for this user account

With Bamboo 5.14, we’re dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13

See Bamboo 5.13 Release Notes

However, we still recommend setting lower_case_table_names=1

**Important**

Changing the value of the lower_case_table_names parameter requires an export/import of all MySQL databases, and might affect functionality of other applications that use the same MySQL installation.

To change the value of the lower_case_table_names parameter:

1. Create a database dump for every database in your MySQL server:
For more information about configuring character set encoding and collation for Bamboo MySQL databases, please refer to the MySQL documentation — Specifying Character Sets and Collations.

2. Connecting Bamboo to the MySQL database

   Bamboo provides two ways to connect to a MySQL database — by using either JDBC or a datasource. JDBC is generally simpler and is the recommended method.

   Connect using JDBC

   1. Download and install the JDBC driver

      The JDBC drivers for MySQL Enterprise Server are no longer bundled with Bamboo (due to licensing restrictions). You need to download and install the driver yourself.

      1. Download the MySQL Connector/J JDBC driver from the download site.
      2. Expand the downloaded zip/tar.gz file.
      3. Copy the mysql-connector-java-5.1.XX-bin.jar file from the extracted directory to the $Bamboo installation directory>/lib directory (create the lib/ directory if it doesn't already exist). If you are using the Java Service Wrapper to start your Bamboo instance (Bamboo/wrapper/run-bamboo start), copy the mysql-connector-java-5.1.XX-bin.jar file to $Bamboo installation directory>/wrapper/lib directory.
      4. Stop Bamboo, on Windows, Linux or Mac.
      5. Restart Bamboo, on Windows, Linux or Mac.

   2. Connect Bamboo to a MySQL database using JDBC

      1. Run the Setup Wizard and choose the Custom Installation method.
      2. On the 'Choose a Database Configuration' page, choose External Database > MySQL 5.1 and click Continue.
      3. Ensure that Direct JDBC connection is selected and complete the following fields (as shown in the screenshot below):

<table>
<thead>
<tr>
<th>Driver Class Name</th>
<th>Type com.mysql.jdbc.Driver (if different from the default).</th>
</tr>
</thead>
</table>

   2. Use DROP DATABASE to drop the database that you're recreating.
   3. Stop your MySQL DB system. You must stop all applications that are using the MySQL instance.
   5. Restart the MySQL service.
   6. Reload the mysqldump for each database to convert the database and table names to lowercase:

   mysql < db1.sql
   mysql < db2.sql

   More information can be found in the MySQL documentation.
### Database URL

Type the URL where Bamboo will access your database (if different from the default). Your URL must include the `autoReconnect=true` flag.

- If you intend to use non-Latin characters in Bamboo, ensure that your URL includes the `useUnicode=true` and `characterEncoding=utf8` flags.
- If your MySQL database server is configured to use a storage engine other than InnoDB by default, ensure that your URL includes the `sessionVariables=storage_engine=InnoDB` flag.

If you include all of these flags, your Database URL should look similar to:

```
jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8&sessionVariables=storage_engine=InnoDB
```

**If the `autoReconnect=true` flag is not specified, the MySQL JDBC driver will eventually time out and Bamboo will no longer be able to communicate with the database.**

For more information on the URL syntax, please see the MySQL documentation.

### User Name

Type the username that Bamboo will use to access your database. This is `bamboouser` defined in section 1 (above).

### Password

Type the password (if required) that Bamboo will use to access your database. This is `password` defined in section 1 (above). Leave this field blank if a password for the database user account was not specified.

---

4. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
5. Click **Continue**.
## Database Configuration

Choose how you wish Bamboo to connect to your database

### Select Database Connection

1. **Direct JDBC connection**
2. **Connect via a datasource (configured in the application server)**

   - **If you are using MySQL, the JDBC URL for the connection must have `autoReconnect=true` set. For example:**
     ```
     jdbc:mysql://localhost/bamboo?autoReconnect=true
     ```
   - **If the autoreconnect flag is not set, the MySQL JDBC driver will eventually time out, and bamboo will no longer be able to communicate with the database.**
   - **If you plan to use non-latin characters, you will also need to add `&useUnicode=true&characterEncoding=utf8` on the end of the above URL. These options are not required for any database other than MySQL.**

### Connectivity Options

- **Driver Class Name:**
  - `com.mysql.jdbc.Driver`  
  - The class name of the database driver. Ensure that this class is in your class path.

- **Database URL:**
  - `jdbc:mysql://localhost/bamboo?autoReconnect=true`  
  - The url to access the database.

- **User Name:**
  - The username to access the database.

- **Password:**
  - (optional) Enter the password if the database configuration requires it.
  - **Overwrite existing data**
    - If you wish Bamboo to overwrite any existing tables that may exist in the database.

### Connect using a datasource

1. Configure a datasource in your application server (consult your application server documentation for details). Please note the following:
   - Ensure that the JDBC URL which you configure in your application server includes the `autoReconnect=true, useUnicode=true, characterEncoding=utf8` flags, such that your database URL should look similar to: `jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8`
   - If your MySQL database server is configured to use a storage engine other than InnoDB by default, also include the `pooling=simultaneous` flag in this URL.
   - If the `autoReconnect` flag is not set, the MySQL JDBC driver will eventually time out and Bamboo will no longer be able to communicate with the database.
   - For more information on the URL syntax, please see the MySQL documentation.

2. **Datasource example:** You can see an example of using Tomcat with a MySQL database as a datasource in the following document: [Tomcat and External MySQL Datasource Example](#).

### Setup Wizard

1. Run the **Setup Wizard** and choose the **Custom Installation** method.
2. Choose **External Database > MySQL 5.1** from the list and click **Continue**.
3. Choose **Connect via a datasource (configured in the application server)** (as shown in the screenshot below).
4. In the **JNDI name** field, type the JNDI name of your datasource, as configured in your application server.
5. **If `java:comp/env/jdbc/DataSourceName` does not work, try `jdbc/DataSourceName` (and vice versa).**
6. Select **Overwrite existing data** if you wish Bamboo to overwrite any existing tables that already exist in the database.
7. Click **Continue**.

_Screenshot 2: Setup Datasource Connection_
1. Creating and Configuring the MySQL database

To connect Bamboo to an external MySQL database, you must first create and configure it. This database must be configured to use:

- utf8 character set encoding, instead of latin1
- utf8_bin collation
- the InnoDB storage engine
- (recommended, not required) lower_case_table_names=1

Setting lower_case_table_names=1 might break other Atlassian applications. For more information, see the steps.

- global transaction isolation level as READ_COMMITTED

If your MySQL database server is configured to use a storage engine other than InnoDB by default (such as MyISAM), then if possible change it to use InnoDB. Otherwise, you can configure Bamboo’s JDBC connection to your MySQL database so that any tables which Bamboo creates in this database will be done using the InnoDB database engine.

A MySQL database administrator can easily create and configure a MySQL database for Bamboo by running the following MySQL commands:

```
mysql> CREATE DATABASE bamboo CHARACTER SET utf8 COLLATE utf8_bin;
mysql> GRANT ALL PRIVILEGES ON bamboo.* TO 'bamboouser'@'localhost'
    IDENTIFIED BY 'password';
mysql> FLUSH PRIVILEGES;
mysql> QUIT
```
This creates an empty MySQL database for Bamboo named bamboo, where:

- `bamboouser` — the user account name for the Bamboo MySQL database
- `localhost` — the host name of the MySQL database server
- `password` — the password for this user account

With Bamboo 5.14, we’re dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13

See See Bamboo 5.13 Release Notes

However, we still recommend setting `lower_case_table_names=1`

**Important**

Changing the value of the `lower_case_table_names` parameter requires an export/import of all MySQL databases, and might affect functionality of other applications that use the same MySQL installation.

To change the value of the `lower_case_table_names` parameter:

1. Create a database dump for every database in your MySQL server:
   
   ```
   mysqlldump --databases db1 > db1.sql
   mysqlldump --databases db2 > db2.sql
   ```

2. Use DROP DATABASE to drop the database that you're recreating.
3. Stop your MySQL DB system. You must stop all applications that are using the MySQL instance.
5. Restart the MySQL service.
6. Reload the `mysqldump` for each database to convert the database and table names to lowercase:

   ```
   mysql < db1.sql
   mysql < db2.sql
   ```

More information can be found in the MySQL documentation.

For more information about configuring character set encoding and collation for Bamboo MySQL databases, refer to the MySQL documentation — Specifying Character Sets and Collations.

## 2. Connecting Bamboo to the MySQL database

Bamboo provides two ways to connect to a MySQL database — by using either JDBC or a datasource. JDBC is generally simpler and is the recommended method.

**Connect using JDBC**

1. Download and install the JDBC driver

   The JDBC drivers for MySQL Enterprise Server are no longer bundled with Bamboo (due to licensing restrictions). You need to download and install the driver yourself.

   1. Download the MySQL Connector/J JDBC driver from the download site.
   2. Expand the downloaded zip/tar.gz file.
   3. Copy the mysql-connector-java-5.1.XX-bin.jar file from the extracted directory to the `<Bamboo installation directory>/lib` directory (create the `lib` directory if it doesn't already exist). If you are using the Java Service Wrapper to start your Bamboo instance (`Bamboo/wrapper/run-bamboo start`), copy the mysql-connector-java-5.1.XX-bin.jar file to `<Bamboo installation directory>` /wrapper/lib directory.
   4. Stop Bamboo, on Windows, Linux or Mac.
   5. Restart Bamboo, on Windows, Linux or Mac.

2. Connect Bamboo to a MySQL database using JDBC

   1. Run the Setup Wizard and choose the Custom Installation method.
   2. On the 'Choose a Database Configuration' page, choose External Database > MySQL 5.1 and click Continue.
   3. Ensure that Direct JDBC connection is selected and complete the following fields (as shown in the screenshot below):

   | Driver Class Name | Type com.mysql.jdbc.Driver (if different from the default). |
### Database URL

Type the URL where Bamboo will access your database (if different from the default). Your URL must include the `autoReconnect=true` flag.

- If you intend to use non-Latin characters in Bamboo, ensure that your URL includes the `useUnicode=true` and `characterEncoding=utf8` flags.
- If your MySQL database server is configured to use a storage engine other than InnoDB by default, ensure that your URL includes the `sessionVariables=storage_engine=InnoDB` flag.

If you include all of these flags, your **Database URL** should look similar to:

```sql
jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8&sessionVariables=storage_engine=InnoDB
```

*If the `autoReconnect=true` flag is not specified, the MySQL JDBC driver will eventually time out and Bamboo will no longer be able to communicate with the database.*

For more information on the URL syntax, see the MySQL documentation.

### User Name

Type the username that Bamboo will use to access your database. This is `bamboouser` defined in section 1 (above).

### Password

Type the password (if required) that Bamboo will use to access your database. This is `password` defined in section 1 (above). Leave this field blank if a password for the database user account was not specified.

4. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
5. Click **Continue**.

*Screenshot: Setup JDBC Connection (MySQL)*
Connect using a datasource

1. Configure a datasource in your application server (consult your application server documentation for details). Please note the following:
   - Ensure that the JDBC URL which you configure in your application server includes the `autoReconnect=true, useUnicode=true, characterEncoding=utf8` flags, such that your database URL should look similar to: `jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8`
   - If your MySQL database server is configured to use a storage engine other than InnoDB by default, also include the `storeVariables=storage_engine=InnoDB` flag in this URL.
   - If the `autoReconnect` flag is not set, the MySQL JDBC driver will eventually time out, and Bamboo will no longer be able to communicate with the database.
   - If you plan to use non-Latin characters, you will also need to add `&useUnicode=true&characterEncoding=UTF8` on the end of the above URL. These options are not required for any database other than MySQL.

2. Run the Setup Wizard and choose the Custom Installation method.
3. Choose External Database > MySQL 5.1 from the list and click Continue.
4. Choose Connect via a datasource (configured in the application server) (as shown in the screenshot below).
5. In the JNDI name field, type the JNDI name of your datasource, as configured in your application server.
   - If `java:comp/env/jdbc/DataSourceName` does not work, try `jdbc/DataSourceName` (and vice versa).
6. Select Overwrite existing data if you wish Bamboo to overwrite any existing tables that may exist in the database.
7. Click Continue.

MySQL v6.1
This page describes how to connect Bamboo to a MySQL database.

On this page:
1. Creating and Configuring the MySQL database
2. Connecting Bamboo to the MySQL database
   Connect using JDBC
   Connect using a datasource

The JDBC driver for MySQL 5.1 (JDBC Connector/J 5.1) is no longer bundled with Bamboo. You must download and install the driver yourself.

See Supported platforms for other information about the versions of MySQL supported by Bamboo.

1. Creating and Configuring the MySQL database

To connect Bamboo to an external MySQL database, you must first create and configure it. This database must be configured to use:

- utf8 character set encoding, instead of latin1
- utf8_bin collation
- the InnoDB storage engine
- (recommended, not required) lower_case_table_names=1

Setting lower_case_table_names=1 might break other Atlassian applications. For more information, see the steps.

- global transaction isolation level as READ_COMMITTED

If your MySQL database server is configured to use a storage engine other than InnoDB by default (such as MyISAM), then if possible change it to use InnoDB. Otherwise, you can configure Bamboo's JDBC connection to your MySQL database so that any tables which Bamboo creates in this database will be done using the InnoDB database engine.

A MySQL database administrator can easily create and configure a MySQL database for Bamboo by running the following MySQL commands:

```
mysql> CREATE DATABASE bamboo CHARACTER SET utf8 COLLATE utf8_bin;
mysql> GRANT ALL PRIVILEGES ON bamboo.* TO 'bamboouser'@'localhost' IDENTIFIED BY 'password';
mysql> FLUSH PRIVILEGES;
mysql> QUIT
```
This creates an empty MySQL database for Bamboo named **bamboo**, where:

- **bamboouser** — the user account name for the Bamboo MySQL database
- **localhost** — the host name of the MySQL database server
- **password** — the password for this user account

With Bamboo 5.14, we’re dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13

See See Bamboo 5.13 Release Notes

However, we still recommend setting **lower_case_table_names=1**

**Important**

Changing the value of the **lower_case_table_names** parameter requires an export/import of all MySQL databases, and might affect functionality of other applications that use the same MySQL installation.

To change the value of the **lower_case_table_names** parameter:

1. Create a database dump for every database in your MySQL server:

```bash
mysql -u <username> -p <password> <database> -e "CALL SYSCONFIGURE('lower_case_table_names', 1);"
```

2. Use DROP DATABASE to drop the database that you're recreating.
3. Stop your MySQL DB system. You must stop all applications that are using the MySQL instance.
4. Add **lower_case_table_names=1** in the [mysqld] section of your MySQL configuration file.
5. Restart the MySQL service.
6. Reload the **mysqldump** for each database to convert the database and table names to lowercase:

```bash
mysql < db1.sql
mysql < db2.sql
```

More information can be found in the MySQL documentation.

For more information about configuring character set encoding and collation for Bamboo MySQL databases, refer to the MySQL 5 documentation — Specifying Character Sets and Collations.

2. **Connecting Bamboo to the MySQL database**

Bamboo provides two ways to connect to a MySQL database — by using either JDBC or a datasource. JDBC is generally simpler and is the recommended method.

**Connect using JDBC**

1. Download and install the JDBC driver

   The JDBC drivers for MySQL Enterprise Server are no longer bundled with Bamboo (due to licensing restrictions). You need to download and install the driver yourself.

   1. Download the MySQL Connector/J JDBC driver from the download site.
   2. Expand the downloaded zip/tar.gz file.
   3. Copy the mysql-connector-java-5.1.XX-bin.jar file from the extracted directory to the `<Bamboo installation directory>/lib` directory (create the `lib` directory if it doesn't already exist). If you are using the Java Service Wrapper to start your Bamboo instance (Bamboo/wrapper/run-bamboo start), copy the mysql-connector-java-5.1.XX-bin.jar file to `<Bamboo installation directory>/wrapper/lib directory`.
   4. Stop Bamboo, on Windows, Linux or Mac.
   5. Restart Bamboo, on Windows, Linux or Mac.

2. Connect Bamboo to a MySQL database using JDBC

   1. Run the **Setup Wizard** and choose the **Custom Installation** method.
   2. On the 'Choose a Database Configuration' page, choose **External Database > MySQL 5.1** and click **Continue**.
   3. Ensure that **Direct JDBC connection** is selected and complete the following fields (as shown in the screenshot below):

      **Driver Class Name**
      `com.mysql.jdbc.Driver` (if different from the default).

      **Database URL**

      More information can be found in the **MySQL documentation**.
Type the URL where Bamboo will access your database (if different from the default). Your URL must include the `autoReconnect=true` flag.

- If you intend to use non-Latin characters in Bamboo, ensure that your URL includes the `useUnicode=true` and `characterEncoding=utf8` flags.
- If your MySQL database server is configured to use a storage engine other than InnoDB by default, ensure that your URL includes the `sessionVariables=storage_engine=InnoDB` flag.

If you include all of these flags, your Database URL should look similar to:

```java
jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8&sessionVariables=storage_engine=InnoDB
```

⚠️ If the `autoReconnect=true` flag is not specified, the MySQL JDBC driver will eventually time out and Bamboo will no longer be able to communicate with the database.

For more information on the URL syntax, see the MySQL documentation.

**User Name**
Type the username that Bamboo will use to access your database. This is `bamboouser` defined in section 1 (above).

**Password**
Type the password (if required) that Bamboo will use to access your database. This is `password` defined in section 1 (above).

Leave this field blank if a password for the database user account was not specified.

4. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.

5. Click **Continue**.

---

**Database Configuration**
Choose how you wish Bamboo to connect to your database.

### Select Database Connection

- **Direct JDBC connection**
- **Connect via a datasource (configured in the application server)**

⚠️ If you are using MySQL, the JDBC URL for the connection must have `autoReconnect=true` set. For example:

```java
jdbc:mysql://localhost/bamboo?autoReconnect=true
```

If the `autoReconnect` flag is not set, the MySQL JDBC driver will eventually time out, and Bamboo will no longer be able to communicate with the database.

- If you plan to use non-Latin characters, you will also need to add `&useUnicode=true&characterEncoding=utf8` on the end of the above URL. These options are not required for any database other than MySQL.

**Driver Class Name:**
`com.mysql.jdbc.Driver`

**Database URL:**
`jdbc:mysql://localhost/bamboo?autoReconnect=true`

**User Name:**

**Password:**

(Optional) Enter the password if the database configuration requires it.

- **Overwrite existing data**

If you wish Bamboo to overwrite any existing tables that may exist in the database.

---

**Connect using a datasource**

1. Configure a datasource in your application server (consult your application server documentation for details). Please note the following:
Ensure that the JDBC URL which you configure in your application server includes the `autoReconnect=true, useUnicode=true, characterEncoding=utf8` flags, such that your database URL should look similar to: `jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8`

If your MySQL database server is configured to use a storage engine other than InnoDB by default, also include the `useUnico` and `flags`, such that your database URL should look similar to:

```
jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8&useUnico=true&flags
```

If the `autoReconnect` flag is not set, the MySQL JDBC driver will eventually time out and Bamboo will no longer be able to communicate with the database.

For more information on the URL syntax, see the MySQL documentation.

Datasource example: You can see an example of using Tomcat with a MySQL database as a datasource in the following document: Tomcat and External MySQL Datasource Example.

1. Run the Setup Wizard and choose the Custom Installation method.
2. Choose External Database > MySQL 5.1 from the list and click Continue.
3. Choose Connect via a datasource (configured in the application server) (as shown in the screenshot below).
4. In the JNDI name field, type the JNDI name of your datasource, as configured in your application server.
   * If `java:comp/env/jdbc/DataSourceName` does not work, try `jdbc/DataSourceName` (and vice versa).
5. If `java:comp/env/jdbc/DataSourceName` does not work, try `jdbc/DataSourceName` (and vice versa).
6. Select Overwrite existing data if you wish Bamboo to overwrite any tables that already exist in the database.
7. Click Continue.

Screenshot 2: Setup Datasource Connection

**Database Configuration**

Choose how you wish Bamboo to connect to your database

**Select Database Connection**

- Direct JDBC connection
- Connect via a datasource (configured in the application server)

![Warning](image)

- If `java:comp/env/jdbc/DataSourceName` does not work, try `jdbc/DataSourceName` (or vice versa).

MySQL v6.6

This page describes how to connect Bamboo to a MySQL database.

On this page:

1. Creating and Configuring the MySQL database
2. Connecting Bamboo to the MySQL database
   - Connect using JDBC
   - Connect using a datasource

**Related pages:**

Troubleshooting Databases

The JDBC driver for MySQL 5.1 (JDBC Connector/J 5.1) is no longer bundled with Bamboo. You must download and install the driver yourself.

See Supported platforms for other information about the versions of MySQL supported by Bamboo.

1. Creating and Configuring the MySQL database

To connect Bamboo to an external MySQL database, you must first create and configure it. This database must be configured to use:

- `utf8` character set encoding, instead of `latin1`
- `utf8_bin` collation
- the InnoDB storage engine
- (recommended, not required) `lower_case_table_names=1`

Setting `lower_case_table_names=1` might break other Atlassian applications. For more information, see the steps.
If your MySQL database server is configured to use a storage engine other than InnoDB by default (such as MyISAM), then if possible change it to use InnoDB. Otherwise, you can configure Bamboo's JDBC connection to your MySQL database so that any tables which Bamboo creates in this database will be done using the InnoDB database engine.

A MySQL database administrator can easily create and configure a MySQL database for Bamboo by running the following MySQL commands:

```sql
mysql> CREATE DATABASE bamboo CHARACTER SET utf8 COLLATE utf8_bin;
mysql> GRANT ALL PRIVILEGES ON bamboo.* TO 'bamboouser'@'localhost'
    IDENTIFIED BY 'password';
mysql> FLUSH PRIVILEGES;
mysql> QUIT
```

This creates an empty MySQL database for Bamboo named `bamboo`, where:

- `bamboouser` — the user account name for the Bamboo MySQL database
- `localhost` — the host name of the MySQL database server
- `password` — the password for this user account

### With Bamboo 5.14, we're dropping the lowercase table names requirement for the external database configuration introduced in Bamboo 5.13

See [Bamboo 5.13 Release Notes](#).

However, we still **recommend** setting `lower_case_table_names=1` in the `[mysqld]` section of your MySQL configuration file.

**Important**

Changing the value of the `lower_case_table_names` parameter requires an export/import of all MySQL databases, and might affect functionality of other applications that use the same MySQL installation.

To change the value of the `lower_case_table_names` parameter:

1. Create a database dump for every database in your MySQL server:
   ```
   mysql> CREATE DATABASE bamboo CHARACTER SET utf8 COLLATE utf8_bin;
   mysql> FLUSH PRIVILEGES;
   mysql> QUIT
   ```

2. Use `DROP DATABASE` to drop the database that you're recreating.
3. Stop your MySQL DB system. You must stop all applications that are using the MySQL instance.
5. Restart the MySQL service.
6. Reload the `mysqldump` for each database to convert the database and table names to lowercase:
   ```
   mysql < db1.sql
   mysql < db2.sql
   ```

More information can be found in the [MySQL documentation](#).

For more information about configuring character set encoding and collation for Bamboo MySQL databases, refer to the [MySQL 5 documentation — Specifying Character Sets and Collations](#).

### 2. Connecting Bamboo to the MySQL database

Bamboo provides two ways to connect to a MySQL database — by using either JDBC or a datasource. JDBC is generally simpler and is the recommended method.

**Connect using JDBC**

1. Download and install the JDBC driver

   The JDBC drivers for MySQL Enterprise Server are no longer bundled with Bamboo (due to licensing restrictions). You need to download
and install the driver yourself.

1. Download the MySQL Connector/J JDBC driver 5.1 from the [download site](http://example.com).
2. Expand the downloaded zip/tar.gz file.
3. Copy the mysql-connector-java-5.1.XX-bin.jar file from the extracted directory to the `<Bamboo installation directory>/lib` directory (create the `lib` directory if it doesn't already exist). If you are using the Java Service Wrapper to start your Bamboo instance, copy the mysql-connector-java-5.1.XX-bin.jar file to `<Bamboo installation directory>/wrapper/lib` directory.
4. Stop Bamboo, on Windows, Linux or Mac.
5. Restart Bamboo, on Windows, Linux or Mac.

2. Connect Bamboo to a MySQL database using JDBC

1. Run the **Setup Wizard** and choose the **Custom Installation** method.
2. On the 'Choose a Database Configuration' page, choose **External Database > MySQL 5.1** and click **Continue**.
3. Ensure that **Direct JDBC connection** is selected and complete the following fields (as shown in the screenshot below):

   **Driver Class Name**
   Type `com.mysql.jdbc.Driver` (if different from the default).

   **Database URL**
   Type the URL where Bamboo will access your database (if different from the default). Your URL *must* include the `autoReconnect=true` flag.
   - If you intend to use non-Latin characters in Bamboo, ensure that your URL includes the `useUnicode=true` and `characterEncoding=utf8` flags.
   - If your MySQL database server is configured to use a storage engine other than InnoDB by default, ensure that your URL includes the `sessionVariables=storage_engine=InnoDB` flag.
   
   If you include all of these flags, your **Database URL** should look similar to:
   
   ```
   jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8&sessionVariables=storage_engine=InnoDB
   ```
   
   *If the `autoReconnect=true` flag is not specified, the MySQL JDBC driver will eventually time out and Bamboo will no longer be able to communicate with the database.*
   
   For more information on the URL syntax, see the MySQL documentation.

   **User Name**
   Type the username that Bamboo will use to access your database. This is `bamboouser` defined in section 1 (above).

   **Password**
   Type the password (if required) that Bamboo will use to access your database. This is `password` defined in section 1 (above).
   Leave this field blank if a password for the database user account was not specified.
4. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
5. Click **Continue**.

**Screenshot: Setup JDBC Connection (MySQL)**
Connect using a datasource

1. Configure a datasource in your application server (consult your application server documentation for details). Please note the following:
   - Ensure that the JDBC URL which you configure in your application server includes the `autoReconnect=true, useUnicode=true` and `characterEncoding=utf8` flags, such that your database URL should look similar to: 
     ```
     jdbc:mysql://localhost/bamboo?autoReconnect=true&useUnicode=true&characterEncoding=utf8
     ```
   - If your MySQL database server is configured to use a storage engine other than InnoDB by default, also include the `sessionVariables=storage_engine=InnoDB` flag in this URL.
   - If the `autoReconnect` flag is not set, the MySQL JDBC driver will eventually time out, and Bamboo will no longer be able to communicate with the database.
   - For more information on the URL syntax, see the MySQL documentation.
   - Datasource example: You can see an example of using Tomcat with a MySQL database as a datasource in the following document: Tomcat and External MySQL Datasource Example.

2. Run the Setup Wizard and choose the Custom Installation method.
3. Choose External Database > MySQL 5.1 from the list and click Continue.
4. Choose Connect via a datasource (configured in the application server) (as shown in the screenshot below).
5. In the JNDI name field, type the JNDI name of your datasource, as configured in your application server.
   - If `java:comp/env/jdbc/DataSourceName` does not work, try `jdbc/DataSourceName` (and vice versa).
6. Select Overwrite existing data if you wish Bamboo to overwrite any existing tables that may exist in the database.
7. Click Continue.

Screenshot 2: Setup Datasource Connection
Oracle
This page describes how to connect Bamboo to an Oracle database.

Bamboo provides two ways to connect to an Oracle database — using JDBC or using a datasource. JDBC is generally simpler and is the recommended method.

See Supported platforms for other information about the versions of Oracle supported by Bamboo.

On this page:
- Configuring Oracle
- Connecting using JDBC
- Connecting using a datasource

### Important
- For JDBC or JNDI connections, please ensure that the user connecting to the database will have total permissions over it. This includes DBMS_LOB package and other resources available.

### Related pages:
- Troubleshooting Databases

### Configuring Oracle
1. Ensure that you have a database instance available for Bamboo (either create a new one or use an existing one).
2. Within that database instance, create a user which Bamboo will connect as (e.g. bamboo-user). Remember this database username, as it will be used to configure Bamboo’s connection to this database.
   - When you create a user in Oracle, Oracle will create a ‘schema’ automatically.

   ```sql
   create user bamboo-user identified by password;
   ```

3. Ensure that the user has the following permissions:

   ```sql
   grant connect, resource, create table to bamboo-user;
   ```

### Connecting using JDBC
1. Run the Setup Wizard and choose the Custom Installation method.
2. At the 'Choose a Database Configuration' step, choose External Database > Oracle.
3. Select Direct JDBC connection and complete the form:
   - Driver Class Name
Type: `oracle.jdbc.driver.OracleDriver`

**Database URL**
Type the URL where Bamboo will access your database, e.g. `jdbc:oracle:thin:@localhost:1521:SID`. For syntax, please see the [Oracle documentation](https://docs.oracle.com/cd/E11882_01/jdev.112/e23104/javaconn.htm#i47119).

**Username**
Type the username that Bamboo will use to access your database.

**Password**
Type the password that Bamboo will use to access your database.

4. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
5. Click **Continue**.

**Screenshot: Setup JDBC Connection (Oracle)**

---

**Connecting using a datasource**

1. Configure a datasource in your application server (consult your application server documentation for details). For the syntax of the JDBC URL to use, please see the [Oracle documentation](https://docs.oracle.com/cd/E11882_01/jdev.112/e23104/javaconn.htm#i47119).
2. Run the Setup Wizard and choose the **Custom Installation** method.
3. At the 'Choose a Database Configuration' step, choose **External Database > Oracle**.
4. Select **Connect using a datasource (configured in the application server)**.
5. In the **JNDI name** field, type the JNDI name of your datasource, as configured in your application server.
   - If `java:comp/env/jdbc/DataSourceName` **doesn't work**, try `jdbc/DataSourceName` *(and vice versa)*.
6. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
7. Click **Continue**.

**Screenshot Setup Datasource Connection**

---

**Oracle v5.14**

This page describes how to connect Bamboo to an Oracle database.

Bamboo provides two ways to connect to an Oracle database — using JDBC or using a datasource. JDBC is generally simpler and is the recommended method.

See [Supported platforms](https://confluence.atlassian.com/bamboo/oracle-supported-platforms-1522291150.html) for other information about the versions of Oracle supported by Bamboo.

On this page:

- Configuring Oracle
- Connecting using JDBC
## Connecting using a datasource

### Important
- For JDBC or JNDI connections, please ensure that the user connecting to the database will have total permissions over it. This includes DBMS_LOB package and other resources available.

---

**Microsoft SQL Server**

This page describes how to connect Bamboo to a Microsoft SQL Server database.

See **Supported platforms** for other information about the versions of SQL Server supported by Bamboo.

Note that the JDBC driver for SQL Server is bundled with Bamboo. You do not have to download and install the driver.

On this page:
1. Configuring SQL Server
2. Creating your database
3. Connecting Bamboo to SQL Server

Connect to SQL Server using JDBCD
Connect to SQL Server using a datasource

Related pages:
- Installing and upgrading
- Connecting Bamboo to an external database
- Troubleshooting Databases

1. Configuring SQL Server

Before you connect Bamboo to a SQL Server, you need to configure SQL Server appropriately.

- **Change server authentication to 'SQL Server and Windows Authentication mode'** — On a typical SQL Server installation, Windows Authentication mode is the default security mode. However, if you try to connect to the database with a database user using this authentication mode, SQL Server will throw an error. You need to change the server authentication mode to SQL Server and Windows Authentication mode in SQL Server before you can connect Bamboo to SQL Server. See this MSDN article for instructions on how to do this.

  ![Screenshot: Changing the SQL Server authentication mode](image)

2. Creating your database

After configuring the SQL Server, you need to create the SQL database.

- **Configure your firewall to allow SQL Server access** — If you need to access SQL server through a firewall, you will need to configure your firewall appropriately. The following MSDN article describes how to configure a Windows firewall to allow SQL Server access, however the instructions are applicable to other firewalls: Configuring the Windows Firewall to Allow SQL Server Access.

- **Enable the TCP/IP protocol for your database instance** — You must enable the TCP/IP protocol for your SQL Server database instance by following the instructions in this MSDN article.
• Create the database for Bamboo — see this MSDN article for instructions.
• Assign the 'db-owner' role on the database for the user that will access the Bamboo database — the 'db_owner' fixed database role allows the user to perform all configuration and maintenance activities on the database. You need to add this role to the Bamboo user used to access your database by updating the login properties for your database user in SQL Server. Read more about login properties for SQL Server.

Screenshot: Adding the 'db_owner' database role to a database user in SQL Server

Please ensure that you use a SQL Server user account to log into your database, not a Windows user account.

• Configure the database to use case-sensitive collation — to make the SQL Server database respect case differences in the data it stores (which is required for Bamboo), ensure that you configure it using a case-sensitive collation option such as 'Latin1_General_CS_AS'. To access this feature in SQL Server Management Studio, right-click on the database name, select Properties from the resulting menu, then select the Options page.

Screenshot: Configuring the Bamboo database to use 'Latin1_General_CS_AS' collation
1. Configure the database to use the correct isolation level— Ensure that the new database was set to use Read Committed with Row Versioning as its isolation level. You can apply the new isolation by executing the following query:

```
ALTER DATABASE <database name>
SET READ_COMMITTED_SNAPSHOT ON
WITH ROLLBACK IMMEDIATE;
```

To verify the changes, use this query which should result in ‘1’:

```
SELECT sd.is_read_committed_snapshot_on
FROM sys.databases AS sd
WHERE sd.[name] = '<database name>';
```

3. Connecting Bamboo to SQL Server

Bamboo provides two ways to connect to a Microsoft SQL Server database — using JDBC or using a datasource. JDBC is generally simpler and is the recommended method.

**Connect to SQL Server using JDBC**

1. Run the Setup Wizard and choose the Custom Installation method.
2. On the Choose a Database Configuration page, choose External Database > Microsoft SQL Server and click Continue.
3. Ensure that Direct JDBC connection has been selected and complete the following fields (as shown in the screenshot below):

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Connect to SQL Server using a datasource

1. Configure a datasource in your application server (consult your application server documentation for details).

   For details about the syntax to use for the SQL Server database URL, please refer to the Microsoft SQL Server documentation.

2. Run the Setup Wizard and choose the Custom Installation method.

3. On the 'Choose a Database Configuration' page, choose External Database > Microsoft SQL Server and click Continue.

4. Choose Connect via a datasource (configured in the application server), as shown in the screenshot below.

5. In the JNDI name field, type the JNDI name of your datasource, as configured in your application server.

   If java:comp/env/jdbc/DataSourceName does not work, try jdbc/DataSourceName (and vice versa).

6. Select Overwrite existing data if you wish Bamboo to overwrite any tables that already exist in the database.

7. Click Continue.
1. Configuring SQL Server

Before you connect Bamboo to a SQL Server, you need to configure SQL Server appropriately.

- Change server authentication to ‘SQL Server and Windows Authentication mode’ — On a typical SQL Server installation, Windows Authentication mode is the default security mode. However, if you try to connect to the database with a database user using this authentication mode, SQL Server will throw an error. You need to change the server authentication mode to SQL Server and Windows Authentication mode in SQL Server before you can connect Bamboo to SQL Server. Please see this MSDN article for instructions on how to do this.

  *Screenshot: Changing the SQL Server authentication mode*
• Configure your firewall to allow SQL Server access — If you need to access SQL server through a firewall, you will need to configure your firewall appropriately. The following MSDN article describes how to configure a Windows firewall to allow SQL Server access, however the instructions are applicable to other firewalls: Configuring the Windows Firewall to Allow SQL Server Access.

• Enable the TCP/IP protocol for your database instance — You must enable the TCP/IP protocol for your SQL Server database instance by following the instructions in this MSDN article.

2. Creating your database

After configuring the SQL Server, you need to create the SQL database.

• Create the database for Bamboo — see this MSDN article for instructions.

• Assign the ‘db-owner’ role on the database for the user that will access the Bamboo database — the ‘db_owner’ fixed database role allows the user to perform all configuration and maintenance activities on the database. You need to add this role to the Bamboo user used to access your database by updating the login properties for your database user in SQL Server. Read more about login properties for SQL Server.

Screenshot: Adding the ‘db_owner’ database role to a database user in SQL Server
Please ensure that you use a SQL Server user account to log into your database, not a Windows user account.

- **Configure the database to use case-sensitive collation** — to make the SQL Server database respect case differences in the data it stores (which is required for Bamboo), ensure that you configure it using a case-sensitive collation option such as 'Latin1_General_CS_AS'. To access this feature in SQL Server Management Studio, right-click on the database name, select **Properties** from the resulting menu, then select the **Options** page.

  Screenshot: Configuring the Bamboo database to use 'Latin1_General_CS_AS' collation
1. Configure the database to use the correct isolation level— Ensure that the new database was set to use Read Committed with Row Versioning as its isolation level. You can apply the new isolation by executing the following query:

```
ALTER DATABASE <database name>
SET READ_COMMITTED_SNAPSHOT ON
WITH ROLLBACK IMMEDIATE;
```

To verify the changes, use this query which should result in '1':

```
SELECT sd.is_read_committed_snapshot_on
FROM sys.databases AS sd
WHERE sd.[name] = '<database name>';
```

2. Connecting Bamboo to SQL Server

Bamboo provides two ways to connect to a Microsoft SQL Server database — using JDBC or using a datasource. JDBC is generally simpler and is the recommended method.

Connect to SQL Server using JDBC

1. Run the Setup Wizard and choose the Custom Installation method.
2. On the Choose a Database Configuration page, choose External Database > Microsoft SQL Server 2005/2008 and click Continue.
3. Ensure that Direct JDBC connection has been selected and complete the following fields (as shown in the screenshot below):

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Database Configuration

Choose how you wish Bamboo to connect to your database

#### Select Database Connection

<table>
<thead>
<tr>
<th>Driver Class Name</th>
<th>Type net.sourceforge.jtds.jdbc.Driver (if different from the default)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database URL</td>
<td>The URL where Bamboo will access your database, e.g. jdbc:jtds:sqlserver://localhost:1433/&lt;database&gt;. If you are connecting to a Named Instance, you will need to append $instance=mssqlnamehere to the connection string, where $mssqlnamehere is the name of your named instance. For more details about syntax, please refer to the Microsoft SQL Server documentation.</td>
</tr>
<tr>
<td>Username</td>
<td>The username that Bamboo will use to access your database.</td>
</tr>
<tr>
<td>Password</td>
<td>The password that Bamboo will use to access your database.</td>
</tr>
</tbody>
</table>

4. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
5. Click **Continue**.

**Screenshot: Set Up JDBC Connection SQL Server 2005/2008**

### Connect to SQL Server using a datasource

1. Configure a datasource in your application server (consult your application server documentation for details).
   - For details about the syntax to use for the SQL Server database URL, please refer to the Microsoft SQL Server documentation.
2. Run the **Setup Wizard** and choose the **Custom Installation** method.
3. On the 'Choose a Database Configuration' page, choose **External Database** > **Microsoft SQL Server 2005/2008** and click **Continue**.
4. Choose **Connect via a datasource** (configured in the application server), as shown in the screenshot below.
5. In the **JNDI name** field, type the JNDI name of your datasource, as configured in your application server.
   - If `java:comp/env/jdbc/DataSourceName` does not work, try `jdbc/DataSourceName` (and vice versa).
6. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
7. Click **Continue**.

**Screenshot: Set up Datasource Connection**
# Connect to SQL Server using JDBC

Before you connect Bamboo to a SQL Server, you need to configure SQL Server appropriately.

- **Change server authentication to 'SQL Server and Windows Authentication mode'** — On a typical SQL Server installation, Windows Authentication mode is the default security mode. However, if you try to connect to the database with a database user using this authentication mode, SQL Server will throw an error. You need to change the server authentication mode to **SQL Server and Windows Authentication mode** in SQL Server before you can connect Bamboo to SQL Server. Please see this [MSDN article](https://docs.microsoft.com/en-us/sql/connections/configure-data-source-name?view=sql-server-ver15) for instructions on how to do this.

  *Screenshot: Changing the SQL Server authentication mode*
Configure your firewall to allow SQL Server access — If you need to access SQL server through a firewall, you will need to configure your firewall appropriately. The following MSDN article describes how to configure a Windows firewall to allow SQL Server access, however the instructions are applicable to other firewalls: Configuring the Windows Firewall to Allow SQL Server Access.

Enable the TCP/IP protocol for your database instance — You must enable the TCP/IP protocol for your SQL Server database instance by following the instructions in this MSDN article.

2. Creating your database

After configuring the SQL Server, you need to create the SQL database.

- Create the database for Bamboo — see this MSDN article for instructions.
- Assign the 'db-owner' role on the database for the user that will access the Bamboo database — the 'db_owner' fixed database role allows the user to perform all configuration and maintenance activities on the database. You need to add this role to the Bamboo user used to access your database by updating the login properties for your database user in SQL Server. Read more about login properties for SQL Server.

Screenshot: Adding the 'db_owner' database role to a database user in SQL Server
Please ensure that you use a SQL Server user account to log into your database, not a Windows user account.

- Configure the database to use case-sensitive collation — to make the SQL Server database respect case differences in the data it stores (which is required for Bamboo), ensure that you configure it using a case-sensitive collation option such as 'Latin1_General_CS_AS'. To access this feature in SQL Server Management Studio, right-click on the database name, select Properties from the resulting menu, then select the Options page.

Screenshot: Configuring the Bamboo database to use 'Latin1_General_CS_AS' collation
1. Configure the database to use the correct isolation level— Ensure that the new database was set to use Read Committed with Row Versioning as its isolation level. You can apply the new isolation by executing the following query:

   ```sql
   ALTER DATABASE <database name>
   SET READ_COMMITTED_SNAPSHOT ON
   WITH ROLLBACK IMMEDIATE;
   ```

   To verify the changes, use this query which should result in '1':

   ```sql
   SELECT sd.is_read_committed_snapshot_on
   FROM sys.databases AS sd
   WHERE sd.[name] = '<database name>';
   ```

3. Connecting Bamboo to SQL Server

   Bamboo provides two ways to connect to a Microsoft SQL Server database — using JDBC or using a datasource. JDBC is generally simpler and is the recommended method.

   Connect to SQL Server using JDBC

   1. Run the Setup Wizard and choose the Custom Installation method.
   2. On the Choose a Database Configuration page, choose External Database > Microsoft SQL Server and click Continue.
   3. Ensure that Direct JDBC connection has been selected and complete the following fields (as shown in the screenshot below):

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Driver Class Name</td>
<td>Type net.sourceforge.jtds.jdbc.Driver (if different from the default)</td>
</tr>
</tbody>
</table>
### Database Configuration

#### Choose how you wish Bamboo to connect to your database

**Select Database Connection**

| Database URL | The URL where Bamboo will access your database, e.g. \`jdbc:jtds:sqlserver://localhost:1433\`\(<database>\). If you are connecting to a Named Instance, you will need to append \`instance=mssqlnamehere\` to the connection string, where `mssqlnamehere` is the name of your named instance. For more details about syntax, please refer to the [Microsoft SQL Server documentation](https://docs.microsoft.com/en-us/sql-server/reporting-services/configure-data-source-name). |
| Username | The username that Bamboo will use to access your database. |
| Password | The password that Bamboo will use to access your database. |

4. **Select Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
5. **Click Continue.**

**Screenshot: Set Up JDBC Connection SQL Server 2005/2008**

### Connect to SQL Server using a datasource

1. **Configure a datasource** in your application server (consult your application server documentation for details).
2. **For details about the syntax to use for the SQL Server database URL, please refer to the Microsoft SQL Server documentation.**
3. **Run the Setup Wizard and choose the Custom Installation method.**
4. **On the 'Choose a Database Configuration' page, choose External Database > Microsoft SQL Server 2005/2008 and click Continue.**
5. **Choose Connect via a datasource (configured in the application server), as shown in the screenshot below.**
6. **In the JNDI name field, type the JNDI name of your datasource, as configured in your application server.**
7. **If `java:comp/env/jdbc/DataSourceName` does not work, try `jdbc/DataSourceName` (and vice versa).**
8. **Select Overwrite existing data if you wish Bamboo to overwrite any tables that already exist in the database.**
9. **Click Continue.**

**Screenshot: Set up Datasource Connection**
This page describes how to connect Bamboo to a Microsoft SQL Server database.

See [Supported platforms](#) for other information about the versions of SQL Server supported by Bamboo.

Note that the JDBC driver for SQL Server is bundled with Bamboo. You do not have to download and install the driver.

On this page:

1. Configuring SQL Server
2. Creating your database
3. Connecting Bamboo to SQL Server
   - Connect to SQL Server using JDBC
   - Connect to SQL Server using a datasource

Related pages:

- Installing and upgrading
- Connecting Bamboo to an external database
- Troubleshooting Databases

1. **Configuring SQL Server**

Before you connect Bamboo to a SQL Server, you need to configure SQL Server appropriately.

- **Change server authentication to 'SQL Server and Windows Authentication mode'** — On a typical SQL Server installation, Windows Authentication mode is the default security mode. However, if you try to connect to the database with a database user using this authentication mode, SQL Server will throw an error. You need to change the server authentication mode to **SQL Server and Windows Authentication mode** in SQL Server before you can connect Bamboo to SQL Server. See this [MSDN article](#) for instructions on how to do this.

    *Screenshot: Changing the SQL Server authentication mode*
Configure your firewall to allow SQL Server access — If you need to access SQL server through a firewall, you will need to configure your firewall appropriately. The following MSDN article describes how to configure a Windows firewall to allow SQL Server access, however the instructions are applicable to other firewalls: Configuring the Windows Firewall to Allow SQL Server Access.

Enable the TCP/IP protocol for your database instance — You must enable the TCP/IP protocol for your SQL Server database instance by following the instructions in this MSDN article.

2. Creating your database

After configuring the SQL Server, you need to create the SQL database.

• Create the database for Bamboo — see this MSDN article for instructions.
• Assign the 'db-owner' role on the database for the user that will access the Bamboo database — the 'db_owner' fixed database role allows the user to perform all configuration and maintenance activities on the database. You need to add this role to the Bamboo user used to access your database by updating the login properties for your database user in SQL Server. Read more about login properties for SQL Server.

Screenshot: Adding the 'db_owner' database role to a database user in SQL Server
Please ensure that you use a SQL Server user account to log into your database, not a Windows user account.

- **Configure the database to use case-sensitive collation** — to make the SQL Server database respect case differences in the data it stores (which is required for Bamboo), ensure that you configure it using a case-sensitive collation option such as 'Latin1_General_CS_AS'. To access this feature in SQL Server Management Studio, right-click on the database name, select **Properties** from the resulting menu, then select the **Options** page.

  *Screenshot: Configuring the Bamboo database to use 'Latin1_General_CS_AS' collation*
1. Configure the database to use the correct isolation level—Ensure that the new database was set to use Read Committed with Row Versioning as its isolation level. You can apply the new isolation by executing the following query:

```
ALTER DATABASE <database name>
SET READ_COMMITTED_SNAPSHOT ON
WITH ROLLBACK IMMEDIATE;
```

To verify the changes, use this query which should result in '1':

```
SELECT sd.is_read_committed_snapshot_on
FROM sys.databases AS sd
WHERE sd.[name] = '<database name>';
```

3. Connecting Bamboo to SQL Server

Bamboo provides two ways to connect to a Microsoft SQL Server database — using JDBC or using a datasource. JDBC is generally simpler and is the recommended method.

Connect to SQL Server using JDBC

1. Run the Setup Wizard and choose the Custom Installation method.
2. On the Choose a Database Configuration page, choose External Database > Microsoft SQL Server and click Continue.
3. Ensure that Direct JDBC connection has been selected and complete the following fields (as shown in the screenshot below):

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Driver Class Name</td>
<td>Type com.microsoft.sqlserver.jdbc.SQLServerDriver (if different from the default)</td>
</tr>
</tbody>
</table>
4. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
5. Click **Continue**.

**Screenshot: Set up JDBC connection**

**Choose how you wish Bamboo to connect to your database**

- **Connection type**: Direct JDBC connection
- **Driver class name**: com.microsoft.sqlserver.jdbc.SQLServerDriver
- **Database URL**: jdbc:sqlserver://localhost:1433;databaseName=databaseName
- **Username**
- **Password**

Connect to SQL Server using a datasource

1. Configure a datasource in your application server (consult your application server documentation for details).
   - For details about the syntax to use for the SQL Server database URL, please refer to the Microsoft SQL Server documentation.
2. Run the Setup Wizard and choose the **Custom Installation** method.
3. On the 'Choose a Database Configuration' page, choose **External Database > Microsoft SQL Server** and click **Continue**.
4. Choose **Connect via a datasource (configured in the application server)**, as shown in the screenshot below.
5. In the **JNDI name** field, type the JNDI name of your datasource, as configured in your application server.
   - If java:comp/env/jdbc/DataSourceName does not work, try jdbc/DataSourceName (and vice versa).
6. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
7. Click **Continue**.

**Screenshot: Set up Datasource connection**
Transitioning from jTDS to Microsoft's JDBC driver

This page describes how to change from using jTDS to using the Microsoft SQL Server JDBC driver to access Microsoft SQL Server.

**What do I have to do?**

Bamboo will try to automatically migrate the database configuration during upgrade. If that fails, the system will lock on startup. To resolve this, you need to manually update the driver class and URL.

**How to proceed**

In the Bamboo server home directory, **bamboo.cfg.xml** must be edited to change the JDBC driver and URL. The existing configuration should look similar to this:

```xml
<property name="hibernate.connection.driver_class">net.sourceforge.jtds.jdbc.Driver</property>
<property name="hibernate.connection.password">PASSWORD</property>
<property name="hibernate.connection.url">jdbc:jtds:sqlserver://127.0.0.1:1433/Bamboo</property>
<property name="hibernate.connection.username">bamboo_user</property>
<property name="hibernate.dialect">com.atlassian.bamboo.hibernate.SQLServerIntlDialect</property>
```

The JDBC URL above is in the format constructed by Bamboo when Connecting to SQL Server and will automatically be updated to a URL compatible with Microsoft's driver, with no change required on the administrator's part. If the URL contains additional properties, such as `domain=`, it will need to be manually updated.

To use Microsoft's SQL Server driver, the settings above would be updated to this:
<property name="hibernate.connection.driver_class">com.microsoft.sqlserver.jdbc.SQLServerDriver</property>
<property name="hibernate.connection.password">your_password</property>
<property name="hibernate.connection.url">jdbc:sqlserver://localhost:1433;databaseName=bamboo</property>
<property name="hibernate.connection.username">username</property>

The exact values to use in the new URL are beyond the scope of this documentation; they must be chosen based on the jTDS settings they are replacing.

Additional Information for the curious

The new JDBC driver class is: com.microsoft.sqlserver.jdbc.SQLServerDriver

The JDBC URL format for the jTDS driver is documented on SourceForge at http://jtds.sourceforge.net/faq.html#urlFormat.

Why change drivers?

Click here to find all the technical details...

Recent releases of Hibernate, which Bamboo uses to simplify its persistence layer, have introduced a requirement that the JDBC drivers and connection pools used be JDBC4-compliant. JDBC4 was introduced with Java 6.

The jTDS driver used by releases prior to Bamboo Server 6.0 is a JDBC3 driver, compatible with Java 1.3, and therefore cannot be used with newer versions of Hibernate. While jTDS 1.3.0 and 1.3.1 claim to implement JDBC4, and JDBC4.1, they actually don't. The new methods have been "implemented", but their implementations are all throw new AbstractMethodError(), which means they can't actually be used. (See an example here, on GitHub.)

Since jTDS 1.3.1 does not provide a functioning JDBC4 implementation, the decision was made to replace jTDS with Microsoft's own SQL Server driver. Microsoft's driver is actively maintained, where jTDS hasn't been updated since 2014 (and prior to the small round of updates done in 2014 it hadn't been updated for multiple years). Microsoft offers a full JDBC4.2 (Java 8) driver and supports all the features of SQL Server, including SQL Server 2016.

Bamboo attempts to automatically update jTDS JDBC URLs to values compatible with Microsoft's JDBC driver. However, for installations using custom JDBC URLs—for example, to use domain authentication—such automatic updating is not possible; the URL, which was manually entered, must be manually updated.

Transitioning from jTDS to Microsoft's JDBC driver v6.0

This page describes how to change from using jTDS to using the Microsoft SQL Server JDBC driver to access Microsoft SQL Server.

What do I have to do?

Bamboo will try to automatically migrate the database configuration during upgrade. If that fails, the system will lock on startup. To resolve this, you need to manually update the driver class and URL.

How to proceed

In the Bamboo server home directory, bamboo.cfg.xml must be edited to change the JDBC driver and URL. The existing configuration should look similar to this:
The JDBC URL above is in the format constructed by Bamboo when connecting to SQL Server and will automatically be updated to a URL compatible with Microsoft's driver, with no change required on the administrator's part. If the URL contains additional properties, such as domain=, it will need to be manually updated.

To use Microsoft's SQL Server driver, the settings above would be updated to this:

```xml
<property name="hibernate.connection.driver_class">com.microsoft.sqlserver.jdbc.SQLServerDriver</property>
<property name="hibernate.connection.password">your_password</property>
<property name="hibernate.connection.url">jdbc:sqlserver://localhost:1433;database Name=bamboo</property>
<property name="hibernate.connection.username">username</property>
<property name="hibernate.dialect">com.atlassian.bamboo.hibernate.SQLServerIntlDialect</property>
```

The exact values to use in the new URL are beyond the scope of this documentation; they must be chosen based on the jTDS settings they are replacing.

Additional Information for the curious

The new JDBC driver class is: `com.microsoft.sqlserver.jdbc.SQLServerDriver`

The JDBC URL format for the jTDS driver is documented on SourceForge at http://jtds.sourceforge.net/faq.html#urlFormat.

Microsoft's driver is actively maintained, where jTDS hasn't been updated since 2014 (and prior to the small round of updates done in 2014 it hadn't been updated for multiple years). Microsoft offers a full JDBC4.2 (Java 8) driver and supports all the features of SQL Server, including SQL Server 2016.

Bamboo attempts to automatically update jTDS JDBC URLs to values compatible with Microsoft's JDBC driver. However, for installations using custom JDBC URLs—for example, to use domain authentication—such automatic updating is not possible; the URL, which was manually entered, must be manually updated.

Viewing your database connection details

When you installed Bamboo, you would have set up a database connection by following one of these processes:

Once Bamboo is running, you can view the database configuration details as follows.

**Related pages:**
- Data and backups

To view your database connection details:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Database Configuration in the left navigation column, under 'System'.

Moving your Bamboo data to a different database

You can move data to a different database by installing a new Bamboo instance and updating the settings. Alternatively, if the database systems are the same or compatible, you can move the data manually.

In the initial Bamboo configuration, the database can be set to:

- an internal H2 database (not recommended for production environments) OR
- an external database.

**Related pages:**
- Data and backups

To move your Bamboo data to a different database:

1. Export the data of the original Bamboo instance as described in Exporting data for backup.
2. Stop the original Bamboo instance.
3. Install a new Bamboo instance as described in Installing and upgrading Bamboo.

**Important**
If you are installing a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same
4. Start the new Bamboo instance.

5. In the Setup Wizard:
   a. Step 1: Make sure that the new Configuration Directory, Build Data Directory and Build Working Directory are not located in the same place as the original Bamboo instance directories.
   b. Step 2: Select a new database:
      • PostgreSQL
      • MySQL
      • Tomcat and External MySQL Datasource Example
      • Oracle
      • Microsoft SQL Server
      • Transitioning from jTDS to Microsoft's JDBC driver
      • Viewing your database connection details
      • Moving your Bamboo data to a different database
   c. Step 3: Select Import existing data and specify the path to the file that you exported at the beginning of the procedure.

6. Once the data is ready, restart the new Bamboo instance.

7. Reindex the data as described in Reindexing data.

8. Verify that your build results and system settings are correct.

Alternative DB migration

If the database systems are:
• the same (for example, you are moving from PostgreSQL to another PostgreSQL) OR
• compatible (for example, you are moving from SQL Server 2005 to SQL Server 2008),
you can move the data manually. To migrate the data:

1. Stop the Bamboo instance that is using the source database.
2. Manually transfer the data.
3. Go to <bamboo-home> and open the bamboo.cfg.xml file.
4. Provide the properties of the new database.
5. Start the Bamboo instance.

Moving your Bamboo data to a different database v5.14

You can move data to a different database by installing a new Bamboo instance and updating the settings. Alternatively, if the database systems are the same or compatible, you can move the data manually.

In the initial Bamboo configuration, the database can be set to:
• an internal HSQL database (not recommended for production environments) OR
• an external database.

To move your Bamboo data to a different database:

1. Export the data of the original Bamboo instance as described in Exporting data for backup.
2. Stop the original Bamboo instance.

You may have to disable automatic Bamboo start if the instance was configured to run as, for example, a Windows service.

3. Install a new Bamboo instance as described in Installing and upgrading Bamboo.

 Important
If you are installing a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same <bamboo-install> or <bamboo-home> paths as the original Bamboo instance. Using the same paths may result in data loss. For more information, see Locating important directories and files.

4. Start the new Bamboo instance.
5. In the Setup Wizard:

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Make sure that the new Configuration Directory, Build Data Directory and Build Working Directory are not located in the same place as the original Bamboo instance directories.</th>
</tr>
</thead>
</table>
| Step 2 | Select a new database:  
- PostgreSQL  
- MySQL  
  - Tomcat and External MySQL Datasource Example  
- Oracle  
- Microsoft SQL Server  
  - Transitioning from jTDS to Microsoft's JDBC driver  
  - Viewing your database connection details  
  - Moving your Bamboo data to a different database |
| Step 3 | Select Import existing data and specify the path to the file that you exported at the beginning of the procedure.  
The data import might take a while. |

6. Once the data is ready, restart the new Bamboo instance.
7. Reindex the data as described in Reindexing data.
8. Verify that your build results and system settings are correct.

**Alternative DB migration**

If the database systems are:
- the same (for example, you are moving from PostgreSQL to another PostgreSQL) OR
- compatible (for example, you are moving from SQL Server 2005 to SQL Server 2008),
you can move the data manually. To migrate the data:

1. Stop the Bamboo instance that is using the source database.
2. Manually transfer the data.
3. Go to `<bamboo-home>` and open the `bamboo.cfg.xml` file.
4. Provide the properties of the new database.
5. Start the Bamboo instance.

### Moving your Bamboo data to a different database v6.1

You can move data to a different database by installing a new Bamboo instance and updating the settings. Alternatively, if the database systems are the same or compatible, you can move the data manually.

In the initial Bamboo configuration, the database can be set to:
- an internal HSQL database (not recommended for production environments) OR
- an external database.

**Related pages:**

- Data and backups

To move your Bamboo data to a different database:

1. Export the data of the original Bamboo instance as described in Exporting data for backup.
2. Stop the original Bamboo instance.
3. Install a new Bamboo instance as described in Installing and upgrading Bamboo.

**Important**

If you are installing a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same `<bamboo-install>` or `<bamboo-home>` paths as the original Bamboo instance. Using the same paths may result in data loss. For more information, see Locating important directories and files.
4. Start the new Bamboo instance.
5. In the Setup Wizard:
   a. Step 1: Make sure that the new Configuration Directory, Build Data Directory and Build Working Directory are not located in the same place as the original Bamboo instance directories.
   b. Step 2: Select a new database:
      - PostgreSQL
      - MySQL
         - Tomcat and External MySQL Datasource Example
      - Oracle
      - Microsoft SQL Server
         - Transitioning from jTDS to Microsoft's JDBC driver
      - Viewing your database connection details
      - Moving your Bamboo data to a different database
   c. Step 3: Select Import existing data and specify the path to the file that you exported at the beginning of the procedure.
      
      The data import might take a while.

6. Once the data is ready, restart the new Bamboo instance.
7. Reindex the data as described in Reindexing data.
8. Verify that your build results and system settings are correct.

**Alternative DB migration**

If the database systems are:
- the same (for example, you are moving from PostgreSQL to another PostgreSQL) OR
- compatible (for example, you are moving from SQL Server 2005 to SQL Server 2008),

you can move the data manually. To migrate the data:

1. Stop the Bamboo instance that is using the source database.
2. Manually transfer the data.
3. Go to `<bamboo-home>` and open the `bamboo.cfg.xml` file.
4. Provide the properties of the new database.
5. Start the Bamboo instance.

### Moving your Bamboo data to a different database v6.3

You can move data to a different database by installing a new Bamboo instance and updating the settings. Alternatively, if the database systems are the same or compatible, you can move the data manually.

In the initial Bamboo configuration, the database can be set to:

- an internal H2 database (not recommended for production environments) OR
- an external database.

**Related pages:**
- Data and backups

**To move your Bamboo data to a different database:**

1. Export the data of the original Bamboo instance as described in Exporting data for backup.
2. Stop the original Bamboo instance.
3. Install a new Bamboo instance as described in Installing and upgrading Bamboo.

   You may have to disable automatic Bamboo start if the instance was configured to run as, for example, a Windows service.

4. Start the new Bamboo instance.
5. In the Setup Wizard:
   a. Step 1: Make sure that the new Configuration Directory, Build Data Directory and Build Working Directory are not located in the same place as the original Bamboo instance directories.
   b. Step 2: Select a new database:
1. Export the data of the original Bamboo instance as described in Exporting data for backup.
2. Stop the original Bamboo instance.
   
   You may have to disable automatic Bamboo start if the instance was configured to run as, for example, a Windows service.

3. Install a new Bamboo instance as described in Installing and upgrading Bamboo.

   **Important**
   If you are installing a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same `<bamboo-install>` or `<bamboo-home>` paths as the original Bamboo instance. Using the same paths may result in data loss. For more information, see Locating important directories and files.

   The import process performed in later steps later can be very memory intensive depending on the size of your import. New installations of Bamboo will come with default Java heap allocation configurations which may not be sufficient to perform the import at an appropriate speed.

   If your Bamboo instance has been in use for long while before migrating and has become quite large, please be sure to...
4. Start the new Bamboo instance.
5. In the Setup Wizard:
   a. Make sure that the new **Configuration Directory**, **Build Data Directory** and **Build Working Directory** are not located in the same place as the original Bamboo instance directories.
   b. Select a new database:
      - PostgreSQL
      - MySQL
      - Tomcat and External MySQL Datasource Example
      - Oracle
      - Microsoft SQL Server
      - Transitioning from jTDS to Microsoft's JDBC driver
      - Viewing your database connection details
      - Moving your Bamboo data to a different database
   c. Select **Import existing data** and specify the path to the file that you exported at the beginning of the procedure.
6. Once the data is ready, restart the new Bamboo instance.
7. Reindex the data as described in **Reindexing data**.
8. Verify that your build results and **system settings** are correct.

**Alternative DB migration**

If the database systems are:

- the same (for example, you are moving from PostgreSQL to another PostgreSQL) OR
- compatible (for example, you are moving from SQL Server 2005 to SQL Server 2008),

you can move the data manually. To migrate the data:

1. Stop the Bamboo instance that is using the source database.
2. Manually transfer the data.
3. Go to `<bamboo-home>` and open the `bamboo.cfg.xml` file.
4. Provide the properties of the new database.
5. Start the Bamboo instance.

**Connecting Bamboo to an external database v6.3**

Bamboo can be connected to an external database. For details and instructions please see:

- PostgreSQL
- MySQL
- Tomcat and External MySQL Datasource Example
- Oracle
- Microsoft SQL Server
- Transitioning from jTDS to Microsoft's JDBC driver
- Viewing your database connection details
- Moving your Bamboo data to a different database
- Troubleshooting Databases

**Connecting Bamboo to an external database v5.14**

Bamboo can be connected to an external database. For details and instructions please see:

- PostgreSQL
- MySQL
- Tomcat and External MySQL Datasource Example
- Oracle
- Microsoft SQL Server
- Transitioning from jTDS to Microsoft's JDBC driver
- Viewing your database connection details

- Troubleshooting Databases

---

**Before you begin**

Please note: if you are already using Bamboo with the embedded HSQL database (or any other database), and you want to keep your data, please see Moving your Bamboo data to a different database.
Add-ons

An add-on is an installable component that supplements or enhances the functionality of Bamboo in some way. For example, the **Jira Bamboo Plugin** is an add-on that integrates Jira and Bamboo. Other add-ons are available for integrating Bamboo into the Visual Studio IDE, running arbitrary commands before or after builds, and accessing Atlassian support from the Bamboo interface.

Bamboo comes with many pre-installed add-ons (called system add-ons). You can install more add-ons, either by acquiring the add-on from the [Atlassian Marketplace](https://marketplace.atlassian.com) or by uploading it from your file system. This means that you can install add-ons that you have developed yourself. For information about developing your own add-ons for Bamboo, see the [Bamboo Developer documentation](https://developer.atlassian.com/bamboo).

You may notice that the terms 'app', 'add-on' and 'plugin' all appear in the Atlassian documentation and tools. While the terms are often used interchangeably, there is a difference. A plugin is a type of app (formerly known as an add-on) that can be installed into an Atlassian host application. Plugins are what developers create with the Atlassian SDK.

About the Universal Plugin Manager (UPM)

You administer add-ons for Bamboo using the Universal Plugin Manager (UPM). The UPM is itself an add-on that exposes add-on administration pages in the Bamboo Administration Console. UPM works across Atlassian applications, providing a consistent interface for administering add-ons in Bamboo, Jira, Confluence, Crucible, Fisheye or Bitbucket.

UPM comes pre-installed in recent versions of all Atlassian applications, so you do not normally need to install it yourself. However, like other add-ons, the UPM software is subject to regular software updates. Before administering add-ons in Bamboo, therefore, you should verify your version of the UPM and update it if needed.

Administering Add-ons in Bamboo

You can update UPM, or any add-on, from the UPM's own add-on administration pages. Additionally, you can perform these tasks from the UPM administration pages:

- Install or remove add-ons
- Configure add-on settings
- Discover and install new add-ons from the Atlassian Marketplace
- Enable or disable add-ons and their component modules

For information on performing these add-on administration tasks, see the [Universal Plugin Manager documentation](https://developer.atlassian.com/bamboo).

For add-on information specific to Bamboo, see these pages:

- **Add-on blacklist**
- **Enabling the Clover add-on**

Add-on blacklist

Outdated add-ons may break certain functionality in Bamboo. If Bamboo detects the presence of a non-working add-on it will print a warning to its logs during startup and ask you to refer to this page.

For more information about why Bamboo printed a particular warning, please refer to a section below that is relevant to the add-on in question.

Experimental Bamboo Git Plugin

Since version 3.0, Bamboo is distributed with a fully supported version of the Bamboo Git Plugin.

The experimental Bamboo Git Plugin that was available before Bamboo 3.0 (and was not distributed with Bamboo) does not work with Bamboo 3.0 and later.

If you were using the experimental Bamboo Git Plugin, please remove the add-on from your Bamboo installation, and manually reconfigure each plan that was using it to use the Bamboo Git Plugin that is distributed with Bamboo.

-.Add-on blacklist v5.14

Outdated add-ons may break certain functionality in Bamboo. If Bamboo detects the presence of a non-working add-on it will print a warning to its logs during startup and ask you to refer to this page.

For more information about why Bamboo printed a particular warning, please refer to a section below that is relevant to the add-on in question.

**Experimental Bamboo Git Plugin**

Since version 3.0, Bamboo is distributed with a fully supported version of the Bamboo Git Plugin.
The experimental Bamboo Git Plugin that was available before Bamboo 3.0 (and was not distributed with Bamboo) does not work with Bamboo 3.0 and later.

If you were using the experimental Bamboo Git Plugin, please remove the add-on from your Bamboo installation, and manually reconfigure each plan that was using it to use the Bamboo Git Plugin that is distributed with Bamboo.

**Add-on blacklist v6.4**

Outdated add-ons may break certain functionality in Bamboo. If Bamboo detects the presence of a non-working add-on it will print a warning to its logs during startup and ask you to refer to this page.

For more information about why Bamboo printed a particular warning, please refer to a section below that is relevant to the add-on in question.

**Experimental Bamboo Git Plugin**

Since version 3.0, Bamboo is distributed with a fully supported version of the Bamboo Git Plugin.

The experimental Bamboo Git Plugin that was available before Bamboo 3.0 (and was not distributed with Bamboo) does not work with Bamboo 3.0 and later.

If you were using the experimental Bamboo Git Plugin, please remove the add-on from your Bamboo installation, and manually reconfigure each plan that was using it to use the Bamboo Git Plugin that is distributed with Bamboo.

**Hung Build Killer**

Starting from version 6.4, Bamboo is shipped with a built-in mechanism for monitoring builds. As a result, the Hung build killer becomes deprecated. If you're using the Hung build killer plugin and you want to upgrade to Bamboo 6.4 or higher, the Hung build killer is going to be disabled after the upgrade.

**Enabling the Clover add-on**

This page describes how to enable and configure Atlassian's Clover add-on for a job in Bamboo.

When Bamboo is integrated with Clover, you can:

- View code-coverage details (i.e. the percentage of code covered by tests) for each build result
- View code-coverage trends for a job over a period of time
- View the code-coverage summary for the job.

On this page:

- Enable the Clover add-on
- Automatic Clover integration
- Manual Clover integration
- Browsing Clover results
- Limit the machines that Clover runs on
- Troubleshooting

**Related pages:**

- Viewing the Clover code-coverage for a build
- Viewing the Clover code-coverage for a plan

- Using Bamboo with Clover

**Atlassian Blogs:**

- Aggregated code coverage using Maven, Clover and Bamboo

Enable the Clover add-on

1. Navigate to the desired job, as described on Configuring jobs.
2. Choose Actions > Configure Job.
3. Click the Miscellaneous tab.
4. Select Use Clover to collect Code Coverage for this build and set the following:
   a. Automatically integrate Clover into this build
      You will need to provide a Clover license, unless this has been configured globally in the Administration panel (Administration > Plugins > Clover Plugin).
   b. Generate a Clover Historical Report
      Displays the current coverage results compared with previous Clover code coverage reports.
c. **Generate a JSON report**
   Provides the Clover results in a format ready for embedding into applications or external report views.

d. **Use plan-defined Clover license key**
   Override the global Clover license for this particular plan.

e. **Clover is already integrated into this build**
   Use this option when you already have Clover-for-Ant, Clover-for-Maven or another Clover integration configured to generate a report.

f. **Clover XML Location**
   Specify the location where Bamboo will look for the XML report file from Clover. Please specify the file path relative to your plan's root directory (e.g. `/home/bamboouser/bamboo-home/xml-data/build-dir/MY_PLAN/`), i.e. do not specify an absolute path.

```
target/site/clover/clover.xml
```

**Screenshot: Settings to enable Clover for a job:**

As Clover integration (automatic and manual) produces instrumented classes, we recommend that you ensure that your job does not install them to production (for instance: `mvn deploy` to public repository, `scp` to an application server running on production, etc ...). Having instrumented code in such locations is usually not desired.

Common practices to ensure proper separation of instrumented and non-instrumented classes are:

- create a dedicated plan or job with Clover integration enabled
- enable automatic Clover integration for jobs running tests only (e.g. "mvn verify")
- use different location of local artifact cache if you need to install artifacts (e.g. `~/.m2/repository-clover` and "mvn install")
- use different URL for uploading artifacts if necessary (e.g. a separate repository for "mvn deploy")

**Automatic Clover integration**

Automatic integration works with Ant, Maven 2.x, Maven 3.x and Grails tasks:

1. Check **Use Clover to collect Code Coverage for this build** in the Clover Code Coverage settings.
2. Select **Automatically integrate Clover into this build.**
3. Enter the global license key for Clover (go to Administration > Plugins > Clover Plugin), or enable **Use plan-defined Clover license key** and paste the key into the text field that appears.

Additionally, you can:

- Select **Generate a Clover Historical Report** to compare the current coverage results with previous Clover code coverage reports.
- Select **Generate a JSON report** to get the Clover results in a format ready for embedding into applications or external report views.
What happens during automatic integration...

When automatic Clover integration is enabled, Bamboo:

- Creates an artifact named **Clover Report (System)**, which is visible on the 'Artifacts' tab for the job.

and during every build:

- Extracts the Clover license (either the global or plan license key) into a temporary file and passes it to:
  - an Ant task as `-Dclover.license.path=<bamboo-home>/xml-data/build-dir/<your-job>/clover/clover.license`
  - a Maven task as `-Dmaven.clover.licenseLocation=<bamboo-home>/xml-data/build-dir/<your-job>/clover/clover.license`
- Enhances tasks by adding:
  - Ant - targets like `with.clover`, `clover.report`
  - Maven - goals like `clover2:setup`, `clover2:aggregate`, `clover2:clover`, `clover2:save-history`; it also adds "verify" phase if original command does not call "compile" or later phase
  - Grails - options like `-clover.on`
- Generates Clover XML and HTML reports (by default)
- Generates statistics and charts for a plan summary

In order to protect you against publishing instrumented code, automatic Clover integration will *not* run if the Maven task runs the "install" or "deploy" phases. In such case, you will find no Clover report and a build log will contain an appropriate warning message. In order to get coverage reports for such job, either edit the Maven task to run the build till the "verify" phase (or earlier) or configure Clover manually.

Manual Clover integration

Manual Clover integration works with any kind of task in which Clover can be called (Ant, Maven 2.x, Maven 3.x, Command, Grails).

1. Check **Use Clover to collect Code Coverage for this build**, in the Clover Code Coverage settings.
2. Check **Clover is already integrated into this build**...
3. Specify in **Clover XML Location** where Bamboo will look for the XML report file generated by Clover.
4. On the 'Artifacts' tab, click **Create Definition** and complete the form as follows:

   **Name**
   This should begin with with "Clover Report".

   **Location**
   This should point to the HTML report directory (e.g. target/site/clover)

   **Copy Pattern**
   Use `**/*.` *

5. Configure Clover in your build script so that it generates both XML and HTML reports.

   **Example for Ant...**

   ```xml
   <clover-report initstring="target/clover/database/clover.db">
     <current outfile="target/site/clover/clover.xml" />
     <current outfile="target/site/clover" />
     <format type="html" />
   </current>
   </clover-report>
   ```
6. Configure the Clover license in your build script or pass it as a proper task parameter in the job configuration:
   a. Save the Clover license key in a file (for example in /opt/bamboo/clover.license).
   b. Pass the location of the license key to the build task:
      • Define it in the build script, or
      • Pass it as a Java property for the Ant/Maven task in the plan configuration.

**Example for Maven...**

```xml
<plugin>
  <groupId>com.atlassian.maven.plugins</groupId>
  <artifactId>maven-clover2-plugin</artifactId>
  <version>3.1.8</version>
  <configuration>
    <licenseLocation>/opt/bamboo/clover.license</licenseLocation>
    <generateXml>true</generateXml>
    <generateHtml>true</generateHtml>
  </configuration>
</plugin>
```

**How to declare the license location in pom.xml...**

```xml
<plugin>
  <groupId>com.atlassian.maven.plugins</groupId>
  <artifactId>maven-clover2-plugin</artifactId>
  <configuration>
    <generateHtml>true</generateHtml>
    <generateXml>true</generateXml>
  </configuration>
</plugin>
```

**How to declare the license location in build.xml...**

```xml
<project>
  <property name="clover.license.path" location="/opt/bamboo/clover.license"/>
  <!-- ... -->
</project>
```

**How to pass the license location for Ant...**

```bash
clean with.clover test clover.report
-Dclover.license.path=/opt/bamboo/clover.license
```

**How to pass the license location for Maven...**

```bash
mvn clean clover2:setup verify clover2:aggregate clover2:clover
-Dmaven.clover.licenseLocation=/opt/bamboo/clover.license
```
After every build, Bamboo will parse the Clover XML file and generate statistics and charts for a plan summary. The Plan summary and job summary pages will contain a “Clover” tab.

Browsing Clover results

Clover HTML report and Clover statistics for a job: see Viewing the Clover code-coverage for a plan.

Clover code coverage summary for a plan: see Viewing the Clover code-coverage for a build.

Clover code coverage statistics across multiple plans: see Generating reports across multiple plans.

Limit the machines that Clover runs on

If you have more remote agents than the number of machines for which Clover is licensed, you can restrict the machines on which Clover runs by using capabilities:

1. For each of the EC2 images on which you would like to run builds with Clover, add a capability such as “clover=true” to the configuration for the image.
   To do this, go to Administration > Elastic Bamboo > Configuration. Select the elastic image and click Add Capability.
2. Now, add a matching requirement, such as “clover=true”, to the configuration for each job.
   To do this, go to Actions > Configure Plan > Jobs. Select the job where Clover runs and click Requirements and then Add Extra Requirement.

Troubleshooting

Automatic or manual Clover integration and spawned processes

Using automatic Clover integration or adding a dependency to the maven-clover2-plugin manually is usually sufficient.

However, if your build spawns another JVM process (for example: unit tests executed in a forked JVM, tests in the container instantiated on the fly, tests calling code deployed on another server), you must manually add the dependency to the Clover JAR for these spawned processes.

See NoClassDefFoundError com.atlassian.clover/CoverageRecorder KB article.

Automatic Clover integration and building in a subdirectory

In case you perform a build in a subdirectory (for instance, in the Maven Task configuration you have the “Working sub directory” field set) and you have automatic Clover integration, you may need to correct the Location in the “Clover Report (System)” artifact. Otherwise, an HTML report may be empty as automatic Clover integration uses the default path (for instance, the “target/site/clover” in case of integration with Maven).

This issue has been fixed in Bamboo 5.7.

Automatic Clover integration and multi-module Maven projects

If you have a multi-module Maven project with dependencies between modules and use Automatic Clover integration, it can happen that an instrumented JAR of the dependent artifact will be taken for test execution in a build phase where Clover was not enabled yet. See BAM-132 08 for more details. In such case, we recommend the following:

- create a separate Job in which automatic Clover integration is enabled
- create a Maven task in this job, which will do nothing (call the “clean” goal, for instance)
- Bamboo will automatically add Clover-related goals (clover2:setup verify clover2:aggregate clover2:clover)

This issue has been fixed in Bamboo 5.9.
Clover Results Collector is unable to find the XML report file

In the build log you may see a warning like:

Failed to execute plugin 'Clover Results Collector' with error: No file matches the specified pattern ...

There are several possible reasons, see this article for more details: Failed to execute plugin 'Clover Results Collector'.

Enabling the Clover add-on v5.14

This page describes how to enable and configure Atlassian's Clover add-on for a job in Bamboo.

When Bamboo is integrated with Clover, you can:

- View code-coverage details (i.e. the percentage of code covered by tests) for each build result
- View code-coverage trends for a job over a period of time
- View the code-coverage summary for the job.

On this page:

- Enable the Clover add-on
- Automatic Clover integration
- Manual Clover integration
- Browsing Clover results
- Limit the machines that Clover runs on
- Troubleshooting

Related pages:

- Viewing the Clover code-coverage for a build
- Viewing the Clover code-coverage for a plan
- Using Bamboo with Clover

Atlassian Blogs:

- Aggregated code coverage using Maven, Clover and Bamboo

Enable the Clover add-on

1. Navigate to the desired job, as described on Configuring jobs.
2. Choose Actions > Configure Job.
3. Click the Miscellaneous tab.
4. Select Use Clover to collect Code Coverage for this build and set the following:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatically integrate Clover into this build</td>
<td>You will need to provide a Clover license, unless this has been configured globally in the Administration panel (Administration &gt; Plugins &gt; Clover Plugin).</td>
</tr>
<tr>
<td>Generate a Clover Historical Report</td>
<td>Displays the current coverage results compared with previous Clover code coverage reports.</td>
</tr>
<tr>
<td>Generate a JSON report</td>
<td>Provides the Clover results in a format ready for embedding into applications or external report views.</td>
</tr>
<tr>
<td>Use plan-defined Clover license key</td>
<td>Override the global Clover license for this particular plan.</td>
</tr>
<tr>
<td>Clover is already integrated into this build</td>
<td>Use this option when you already have Clover-for-Ant, Clover-for-Maven or another Clover integration configured to generate a report.</td>
</tr>
</tbody>
</table>
**Clover XML Location**

Specify the location where Bamboo will look for the XML report file from Clover. Please specify the file path **relative to your plan’s root directory** (e.g. `/home/bamboouser/bamboo-home/xml-data/build-dir/MY_PLAN/`), i.e. do not specify an absolute path.

```
target/site/clover/clover.xml
```

**Screenshot: Settings to enable Clover for a job:**

**Would you like to view Clover Code Coverage for this plan?**

- [ ] Use Clover to collect Code Coverage for this build.
  
  Clover is a code coverage tool reports how well tested your code is and also highlights parts of code that require more testing. For more information visit Atlassian Clover or view the online documentation.
  
  **Attention:** As Clover modifies your classes, ensure that you will not publish them to production - more details here.

**Integration Options**

- [ ] Automatically integrate Clover into this build.
- [ ] Clover is already integrated into this build and a clover.xml file will be produced.
- [ ] Generate a Clover Historical Report
  
  Include coverage trends and class movers in the Clover HTML report. More info.
  
  (Will only work consistently if this plan is run on a single agent and no clean checkout is performed.)
- [ ] Generate a JSON report
  
  JSON makes it very easy to integrate Clover data into a web-page. Learn how.

**Global Clover license has been configured in administration panel. To override use option below:**

- [ ] Use plan-defined Clover license key
  
  Override globally defined Clover license and provide dedicated license for this plan.

As Clover integration (automatic and manual) produces instrumented classes, we recommend that you ensure that your job does not install them to production (for instance: ‘mvn deploy’ to public repository, ‘scp’ to an application server running on production, etc ...). Having instrumented code in such locations is usually not desired.

Common practices to ensure proper separation of instrumented and non-instrumented classes are:

- create a dedicated plan or job with Clover integration enabled
- enable automatic Clover integration for jobs running tests only (e.g. "mvn verify")
- use different location of local artifact cache if you need to install artifacts (e.g. ~/.m2/repository-clover and "mvn install")
- use different URL for uploading artifacts if necessary (e.g. a separate repository for "mvn deploy")

**Automatic Clover integration**

Automatic integration works with Ant, Maven 2.x, Maven 3.x and Grails tasks:

1. Check **Use Clover to collect Code Coverage for this build** in the Clover Code Coverage settings.
2. Select **Automatically integrate Clover into this build**.
3. Enter the global license key for Clover (go to Administration > Plugins > Clover Plugin), or enable **Use plan-defined Clover license key** and paste the key into the text field that appears.

Additionally, you can:

- Select **Generate a Clover Historical Report** to compare the current coverage results with previous Clover code coverage reports.
- Select **Generate a JSON report** to get the Clover results in a format ready for embedding into applications or external report views.

**Behavior of automatic integration has changed in Bamboo 5.9**

Automatic Clover integration for Maven 2 and Maven 3 tasks has been improved in **Bamboo 5.9**. It became tighter and now it adds Clover goals between goals from the original command in such way that a build is performed only once. It does not run "clean" and "verify" separately any more. Thanks to this, builds with automatic Clover integration may be as twice as fast.
In order to protect you against publishing instrumented code, automatic Clover integration **will not** run if the Maven task runs the "install" or "deploy" phases. In such case, you will find no Clover report and a build log will contain an appropriate warning message. In order to get coverage reports for such job, either edit the Maven task to run the build till the "verify" phase (or earlier) or configure Clover manually.

Automatic Clover integration before Bamboo 5.9 was adding Clover goals at the end of the original Maven command. As a consequence, build was performed twice (first - original goals/phases, next - with Clover enabled and the "verify" phase), which had it’s advantages (better, but not full, separation of instrumented and non-instrumented code) and drawbacks (build times as twice as long, problems with artifact dependencies in maven-surefire-plugin or maven-assembly-plugin as described in BAM-13208).

**What happens during automatic integration...**

When automatic Clover integration is enabled, Bamboo:

- Creates an artifact named **Clover Report (System)**, which is visible on the 'Artifacts' tab for the job.

**and during every build:**

- Extracts the Clover license (either the global or plan license key) into a temporary file and passes it to:
  - an Ant task as `-Dclover.license.path=<bamboo-home>/xml-data/build-dir/<your-job>/.clover/clover.license`
  - a Maven task as `-Dmaven.clover.licenseLocation=<bamboo-home>/xml-data/build-dir/<your-job>/.clover/clover.license`
- Enhances tasks by adding
  - Ant - targets like `with.clover`, `clover.report`
  - Maven - goals like `clover2:setup`, `clover2:aggregate`, `clover2:clover`, `clover2:save-history`; it also adds "verify" phase if original command does not call "compile" or later phase
  - Grails - options like `--clover.on`
- Generates Clover XML and HTML reports (by default)
- Generates statistics and charts for a plan summary

**Manual Clover integration**

Manual Clover integration works with any kind of task in which Clover can be called (Ant, Maven 2.x, Maven 3.x, Command, Grails).

1. Check **Use Clover to collect Code Coverage for this build**, in the Clover Code Coverage settings.
2. Check **Clover is already integrated into this build...**
3. Specify in **Clover XML Location** where Bamboo will look for the XML report file generated by Clover.
4. On the 'Artifacts' tab, click **Create Definition** and complete the form as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>This should begin with with &quot;Clover Report&quot;.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location</td>
<td>This should point to the HTML report directory (e.g. target/site/clover)</td>
</tr>
<tr>
<td>Copy Pattern</td>
<td>Use &quot;/*/&quot;.</td>
</tr>
</tbody>
</table>

5. Configure Clover in your build script so that it generates both XML and HTML reports.

**Example for Ant...**
5. Example for Maven...

```xml
<plugin>
  <groupId>com.atlassian.maven.plugins</groupId>
  <artifactId>maven-clover2-plugin</artifactId>
  <version>3.1.8</version>
  <configuration>
    <licenseLocation>/opt/bamboo/clover.license</licenseLocation>
    <generateXml>true</generateXml>
    <generateHtml>true</generateHtml>
  </configuration>
</plugin>
```

6. Configure the Clover license in your build script or pass it as a proper task parameter in the job configuration:
   a. Save the Clover license key in a file (for example in `/opt/bamboo/clover.license`).
   b. Pass the location of the license key to the build task:
      * Define it in the build script, or
      * Pass it as a Java property for the Ant/Maven task in the plan configuration.

   **How to declare the license location in pom.xml...**

```xml
<plugin>
  <groupId>com.atlassian.maven.plugins</groupId>
  <artifactId>maven-clover2-plugin</artifactId>
  <configuration>
    <licenseLocation>/opt/bamboo/clover.license</licenseLocation>
    <generateXml>true</generateXml>
    <generateHtml>true</generateHtml>
  </configuration>
</plugin>
```

**How to declare the license location in build.xml...**

```xml
<project>
  <property name="clover.license.path" location="/opt/bamboo/clover.license"/>
  <!-- ... -->
</project>
```

**How to pass the license location for Ant...**

```
clean with.clover test clover.report
-Dclover.license.path=/opt/bamboo/clover.license
```

**How to pass the license location for Maven...**
After every build, Bamboo will parse the Clover XML file and generate statistics and charts for a plan summary. The Plan summary and job summary pages will contain a “Clover” tab.

### Browsing Clover results

Clover HTML report and Clover statistics for a job: see Viewing the Clover code-coverage for a plan.

Clover code coverage summary for a plan: see Viewing the Clover code-coverage for a build.

Clover code coverage statistics across multiple plans: see Generating reports across multiple plans.

### Limit the machines that Clover runs on

If you have more remote agents than the number of machines for which Clover is licensed, you can restrict the machines on which Clover runs by using capabilities:

1. For each of the EC2 images on which you would like to run builds with Clover, add a capability such as “clover=true” to the configuration for the image.
   
   To do this, go to Administration > Elastic Bamboo > Configuration. Select the elastic image and click Add Capability.

2. Now, add a matching requirement, such as “clover=true”, to the configuration for each job.
   
   To do this, go to Actions > Configure Plan > Jobs. Select the job where Clover runs and click Requirements and then Add Extra Requirement.

### Troubleshooting

**Automatic or manual Clover integration and spawned processes**

Using automatic Clover integration or adding a dependency to the maven-clover2-plugin manually is usually sufficient.

However, if your build spawns another JVM process (for example: unit tests executed in a forked JVM, tests in the container instantiated on the fly, tests calling code deployed on another server), you must manually add the dependency to the Clover JAR for these spawned processes.

See NoClassDefFoundError com_atlassian_clover/CoverageRecorder KB article.

**Automatic Clover integration and building in a subdirectory**

In case you perform a build in a subdirectory (for instance, in the Maven Task configuration you have the “Working sub directory” field set) and you have automatic Clover integration, you may need to correct the Location in the “Clover Report (System)” artifact. Otherwise, an HTML report may be empty as automatic Clover integration uses the default path (for instance, the “target/site/clover” in case of integration with Maven).

This issue has been fixed in Bamboo 5.7.

**Automatic Clover integration and multi-module Maven projects**

If you have a multi-module Maven project with dependencies between modules and use Automatic Clover integration, it can happen that an instrumented JAR of the dependent artifact will be taken for test execution in a build phase where Clover was not enabled yet. See BAM-132
08 for more details. In such case, we recommend the following:

- create a separate Job in which automatic Clover integration is enabled
- create a Maven task in this job, which will do nothing (call the "clean" goal, for instance)
- Bamboo will automatically add Clover-related goals (clover2:setup verify clover2:aggregate clover2:clover)

This issue has been fixed in Bamboo 5.9.

_Clover Results Collector is unable to find the XML report file_

In the build log you may see a warning like:

```
Failed to execute plugin 'Clover Results Collector' with error: No file matches the specified pattern
```

The are several possible reasons, see this article for more details: Failed to execute plugin 'Clover Results Collector'.

---

### Enabling the Clover add-on v5.15

This page describes how to enable and configure Atlassian’s Clover add-on for a job in Bamboo.

When Bamboo is integrated with Clover, you can:

- View code-coverage details (i.e. the percentage of code covered by tests) for each build result
- View code-coverage trends for a job over a period of time
- View the code-coverage summary for the job.

On this page:

- Enable the Clover add-on
- Automatic Clover integration
- Manual Clover integration
- Browsing Clover results
- Limit the machines that Clover runs on
- Troubleshooting

**Related pages:**

- Viewing the Clover code-coverage for a build
- Viewing the Clover code-coverage for a plan

**Atlassian Blogs:**

- Aggregated code coverage using Maven, Clover and Bamboo

### Enable the Clover add-on

1. Navigate to the desired job, as described on Configuring jobs.
2. Choose Actions > Configure Job.
3. Click the Miscellaneous tab.
4. Select **Use Clover to collect Code Coverage for this build** and set the following:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatically integrate Clover into</td>
<td>You will need to provide a Clover license, unless this has been configured globally in the Administration panel (Administration &gt; Plugins &gt; Clover Plugin).</td>
</tr>
<tr>
<td>this build</td>
<td></td>
</tr>
<tr>
<td>• Generate a Clover Historical Report</td>
<td>Displays the current coverage results compared with previous Clover code coverage reports.</td>
</tr>
<tr>
<td>• Generate a JSON report</td>
<td>Provides the Clover results in a format ready for embedding into applications or external report views.</td>
</tr>
<tr>
<td>• Use plan-defined Clover license key</td>
<td>Override the global Clover license for this particular plan.</td>
</tr>
</tbody>
</table>
Clover is already integrated into this build

- Clover XML Location

Specify the location where Bamboo will look for the XML report file from Clover. Please specify the file path relative to your plan's root directory (e.g. `/home/bamboouser/bamboo-home/xml-data/build-dir/MY_PLAN/`), i.e. do not specify an absolute path.

```plaintext
target/site/clover/clover.xml
```

**Screenshot: Settings to enable Clover for a job:**

As Clover integration (automatic and manual) produces instrumented classes, we recommend that you ensure that your job does not install them to production (for instance: `mvn deploy` to public repository, `scp` to an application server running on production, etc ...). Having instrumented code in such locations is usually not desired.

Common practices to ensure proper separation of instrumented and non-instrumented classes are:

- create a dedicated plan or job with Clover integration enabled
- enable automatic Clover integration for jobs running tests only (e.g. `mvn verify`)
- use different location of local artifact cache if you need to install artifacts (e.g. `~/.m2/repository-clover` and `mvn install`)
- use different URL for uploading artifacts if necessary (e.g. a separate repository for `mvn deploy`)

**Automatic Clover integration**

Automatic integration works with Ant, Maven 2.x, Maven 3.x and Grails tasks:

1. Check **Use Clover to collect Code Coverage for this build** in the Clover Code Coverage settings.
2. Select **Automatically integrate Clover into this build**.
3. Enter the global license key for Clover (go to Administration > Plugins > Clover Plugin), or enable **Use plan-defined Clover license key** and paste the key into the text field that appears.

Additionally, you can:

- Select **Generate a Clover Historical Report** to compare the current coverage results with previous Clover code coverage reports.
- Select **Generate a JSON report** to get the Clover results in a format ready for embedding into applications or external report views.
Behavior of automatic integration has changed in Bamboo 5.9

Automatic Clover integration for Maven 2 and Maven 3 tasks has been improved in **Bamboo 5.9**. It became tighter and now it adds Clover goals between goals from the original command in such way that a build is performed only once. It does not run "clean" and "verify" separately any more. Thanks to this, builds with automatic Clover integration may be as twice as fast.

In order to protect you against publishing instrumented code, automatic Clover integration **will not** run if the Maven task runs the "install" or "deploy" phases. In such case, you will find no Clover report and a build log will contain an appropriate warning message. In order to get coverage reports for such job, either edit the Maven task to run the build till the "verify" phase (**or earlier**) or configure Clover manually.

Automatic Clover integration before Bamboo 5.9 was adding Clover goals at the end of the original Maven command. As a consequence, build was performed twice (first - original goals/phases, next - with Clover enabled and the "verify" phase), which had it's advantages (better, but not full, separation of instrumented and non-instrumented code) and drawbacks (build times as twice as long, problems with artifact dependencies in maven-surefire-plugin or maven-assembly-plugin as described in **BAM-13208**).

---

**What happens during automatic integration...**

When automatic Clover integration is enabled, Bamboo:

- Creates an artifact named **Clover Report (System)**, which is visible on the 'Artifacts' tab for the job.

...and during every build:

- Extracts the Clover license (either the global or plan license key) into a temporary file and passes it to:
  - an Ant task as `-Dclover.license.path=/<bamboo-home>/xml-data/build-dir/<your-job>/.clover/clover.license`
  - a Maven task as `-Dmaven.clover.licenseLocation=/<bamboo-home>/xml-data/build-dir/<your-job>/.clover/clover.license`

- Enhances tasks by adding:
  - Ant - targets like "with.clover", "clover:report"
  - Maven - goals like "clover2:setup", "clover2:aggregate", "clover2:clover", "clover2:save-history"; it also adds "verify" phase if original command does not call "compile" or later phase
  - Grails - options like "-clover.on"

- Generates Clover XML and HTML reports (by default)
- Generates statistics and charts for a plan summary

---

**Manual Clover integration**

Manual Clover integration works with any kind of task in which Clover can be called (Ant, Maven 2.x, Maven 3.x, Command, Grails).

1. Check **Use Clover to collect Code Coverage for this build**, in the Clover Code Coverage settings.
2. Check **Clover is already integrated into this build**...
3. Specify in **Clover XML Location** where Bamboo will look for the XML report file generated by Clover.
4. On the 'Artifacts' tab, click **Create Definition** and complete the form as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>This should begin with with &quot;Clover Report&quot;.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location</td>
<td>This should point to the HTML report directory (e.g. target/site/clover)</td>
</tr>
<tr>
<td>Copy Pattern</td>
<td>Use &quot;.*&quot;.</td>
</tr>
</tbody>
</table>

5. Configure Clover in your build script so that it generates both XML and HTML reports.

**Example for Ant...**
<clover-report initstring="target/clover/database/clover.db">
  <current outfile="target/site/clover/clover.xml" />
  <current outfile="target/site/clover"/>
  <format type="html"/>
</current>
</clover-report>

Example for Maven...

<plugin>
  <groupId>com.atlassian.maven.plugins</groupId>
  <artifactId>maven-clover2-plugin</artifactId>
  <configuration>
    <generateHtml>true</generateHtml>
    <generateXml>true</generateXml>
  </configuration>
</plugin>

Configure the Clover license in your build script or pass it as a proper task parameter in the job configuration:

a. Save the Clover license key in a file (for example in /opt/bamboo/clover.license).
b. Pass the location of the license key to the build task:
   * Define it in the build script, or
   * Pass it as a Java property for the Ant/Maven task in the plan configuration.

How to declare the license location in pom.xml...

<plugin>
  <groupId>com.atlassian.maven.plugins</groupId>
  <artifactId>maven-clover2-plugin</artifactId>
  <version>3.1.8</version>
  <configuration>
    <licenseLocation>/opt/bamboo/clover.license</licenseLocation>
    <generateXml>true</generateXml>
    <generateHtml>true</generateHtml>
  </configuration>
</plugin>

How to declare the license location in build.xml...

<project>
  <property name="clover.license.path" location="/opt/bamboo/clover.license"/>
  <!-- ... -->
</project>

How to pass the license location for Ant...

clean with.clover test clover.report
-Dclover.license.path=/opt/bamboo/clover.license

How to pass the license location for Maven...
mvn clean clover2:setup verify clover2:aggregate clover2:clover
-Dmaven.clover.licenseLocation=/opt/bamboo/clover.license

After every build, Bamboo will parse the Clover XML file and generate statistics and charts for a plan summary. The Plan summary and job summary pages will contain a “Clover” tab.

Browsing Clover results

Clover HTML report and Clover statistics for a job: see Viewing the Clover code-coverage for a plan.

Clover code coverage summary for a plan: see Viewing the Clover code-coverage for a build.

Clover code coverage statistics across multiple plans: see Generating reports across multiple plans.

Limit the machines that Clover runs on

If you have more remote agents than the number of machines for which Clover is licensed, you can restrict the machines on which Clover runs by using capabilities:

1. For each of the EC2 images on which you would like to run builds with Clover, add a capability such as “clover=true” to the configuration for the image.
   To do this, go to Administration > Elastic Bamboo > Configuration. Select the elastic image and click Add Capability.
2. Now, add a matching requirement, such as “clover=true”, to the configuration for each job.
   To do this, go to Actions > Configure Plan > Jobs. Select the job where Clover runs and click Requirements and then Add Extra Requirement.

Troubleshooting

Automatic or manual Clover integration and spawned processes

Using automatic Clover integration or adding a dependency to the maven-clover2-plugin manually is usually sufficient.

However, if your build spawns another JVM process (for example: unit tests executed in a forked JVM, tests in the container instantiated on the fly, tests calling code deployed on another server), you must manually add the dependency to the Clover JAR for these spawned processes.

See NoClassDefFoundError com_atlassian_clover/CoverageRecorder KB article.

Automatic Clover integration and building in a subdirectory

In case you perform a build in a subdirectory (for instance, in the Maven Task configuration you have the “Working sub directory” field set) and you have automatic Clover integration, you may need to correct the Location in the “Clover Report (System)” artifact. Otherwise, an HTML report may be empty as automatic Clover integration uses the default path (for instance, the “target/site/clover” in case of integration with Maven).

This issue has been fixed in Bamboo 5.7.

Automatic Clover integration and multi-module Maven projects

If you have a multi-module Maven project with dependencies between modules and use Automatic Clover integration, it can happen that an instrumented JAR of the dependent artifact will be taken for test execution in a build phase where Clover was not enabled yet. See BAM-132
Enable the Clover add-on

1. Navigate to the desired job, as described on Configuring jobs.
2. Choose Actions > Configure Job.
3. Click the Miscellaneous tab.
4. Select Use Clover to collect Code Coverage for this build and set the following:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatically integrate Clover into this build</td>
<td>You will need to provide a Clover license, unless this has been configured globally in the Administration panel (Administration &gt; Plugins &gt; Clover Plugin).</td>
</tr>
<tr>
<td>Generate a Clover Historical Report</td>
<td>Displays the current coverage results compared with previous Clover code coverage reports.</td>
</tr>
<tr>
<td>Generate a JSON report</td>
<td>Provides the Clover results in a format ready for embedding into applications or external report views.</td>
</tr>
<tr>
<td>Use plan-defined Clover license key</td>
<td>Override the global Clover license for this particular plan.</td>
</tr>
</tbody>
</table>
Clover is already integrated into this build

Use this option when you already have Clover-for-Ant, Clover-for-Maven or another Clover integration configured to generate a report.

- **Clover XML Location**

  Specify the location where Bamboo will look for the XML report file from Clover. Please specify the file path relative to your plan's root directory (e.g. `/home/bamboouser/bamboo-home/xml-data/build-dir/My_PLAN/`), i.e. do not specify an absolute path.

  target/site/clover/clover.xml

**Screenshot: Settings to enable Clover for a job:**

As Clover integration (automatic and manual) produces instrumented classes, we recommend that you ensure that your job does not install them to production (for instance: ‘mvn deploy’ to public repository, ‘scp’ to an application server running on production, etc...). Having instrumented code in such locations is usually not desired.

Common practices to ensure proper separation of instrumented and non-instrumented classes are:

- create a dedicated plan or job with Clover integration enabled
- enable automatic Clover integration for jobs running tests only (e.g. "mvn verify")
- use different location of local artifact cache if you need to install artifacts (e.g. `~/.m2/repository-clover` and "mvn install")
- use different URL for uploading artifacts if necessary (e.g. a separate repository for "mvn deploy")

**Automatic Clover integration**

Automatic integration works with Ant, Maven 2.x, Maven 3.x and Grails tasks:

1. Check **Use Clover to collect Code Coverage for this build** in the Clover Code Coverage settings.
2. Select **Automatically integrate Clover into this build**.
3. Enter the global license key for Clover (go to Administration > Plugins > Clover Plugin), or enable **Use plan-defined Clover license key** and paste the key into the text field that appears.

Additionally, you can:

- Select **Generate a Clover Historical Report** to compare the current coverage results with previous Clover code coverage reports.
- Select **Generate a JSON report** to get the Clover results in a format ready for embedding into applications or external report views.
What happens during automatic integration...

When automatic Clover integration is enabled, Bamboo:

- Creates an artifact named **Clover Report (System)**, which is visible on the 'Artifacts' tab for the job.

and during every build:

- Extracts the Clover license (either the global or plan license key) into a temporary file and passes it to:
  - an Ant task as `-Dclover.license.path=<bamboo-home>/xml-data/build-dir/<your-job>/clover/clover.license`
  - a Maven task as `-Dmaven.clover.licenseLocation=<bamboo-home>/xml-data/build-dir/<your-job>/clover/clover.license`

- Enhances tasks by adding
  - Ant - targets like `with.clover` and `clover.report`
  - Maven - goals like `clover2:setup`, `clover2:aggregate`, `clover2:clover`, `clover2:save-history`; it also adds "verify" phase if original command does not call "compile" or later phase
  - Grails - options like `-clover.on`

- Generates Clover XML and HTML reports (by default)
- Generates statistics and charts for a plan summary

In order to protect you against publishing instrumented code, automatic Clover integration will **not** run if the Maven task runs the "install" or "deploy" phases. In such case, you will find no Clover report and a build log will contain an appropriate warning message. In order to get coverage reports for such job, either edit the Maven task to run the build till the "verify" phase (or earlier) or configure Clover manually.

Manual Clover integration

Manual Clover integration works with any kind of task in which Clover can be called (Ant, Maven 2.x, Maven 3.x, Command, Grails).

1. Check **Use Clover to collect Code Coverage for this build**, in the Clover Code Coverage settings.
2. Check **Clover is already integrated into this build** ...
3. Specify in **Clover XML Location** where Bamboo will look for the XML report file generated by Clover.
4. On the 'Artifacts' tab, click **Create Definition** and complete the form as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>This should begin with &quot;Clover Report&quot;.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location</td>
<td>This should point to the HTML report directory (e.g. target/site/clover)</td>
</tr>
<tr>
<td>Copy Pattern</td>
<td>Use '**/.*'</td>
</tr>
</tbody>
</table>

5. Configure Clover in your build script so that it generates both XML and HTML reports.

   **Example for Ant...**

   ```xml
   <clover-report initstring="target/clover/database/clover.db">
   <current outfile="target/site/clover/clover.xml" />
   <current outfile="target/site/clover">
     <format type="html"/>
   </current>
   </clover-report>
   ```

   **Example for Maven...**
5. How to declare the license location in pom.xml...

```xml
<plugin>
  <groupId>com.atlassian.maven.plugins</groupId>
  <artifactId>maven-clover2-plugin</artifactId>
  <version>3.1.8</version>
  <configuration>
    <licenseLocation>/opt/bamboo/clover.license</licenseLocation>
    <generateXml>true</generateXml>
    <generateHtml>true</generateHtml>
  </configuration>
</plugin>
```

6. Configure the Clover license in your build script or pass it as a proper task parameter in the job configuration:
   a. Save the Clover license key in a file (for example in `/opt/bamboo/clover.license`).
   b. Pass the location of the license key to the build task:
      • Define it in the build script, or
      • Pass it as a Java property for the Ant/Maven task in the plan configuration.

   - How to declare the license location in pom.xml...

```xml
<plugin>
  <groupId>com.atlassian.maven.plugins</groupId>
  <artifactId>maven-clover2-plugin</artifactId>
  <configuration>
    <licenseLocation>/opt/bamboo/clover.license</licenseLocation>
    <generateXml>true</generateXml>
    <generateHtml>true</generateHtml>
  </configuration>
</plugin>
```

- How to declare the license location in build.xml...

```xml
<project>
  <property name="clover.license.path" location="/opt/bamboo/clover.license"/>
  <!-- ... -->
</project>
```

- How to pass the license location for Ant...

```bash
clean with.clover test clover.report
-Dclover.license.path=/opt/bamboo/clover.license
```

- How to pass the license location for Maven...

```bash
mvn clean clover2:setup verify clover2:aggregate clover2:clover
-Dmaven.clover.licenseLocation=/opt/bamboo/clover.license
```
After every build, Bamboo will parse the Clover XML file and generate statistics and charts for a plan summary. The Plan summary and job summary pages will contain a “Clover” tab.

**Browsing Clover results**

Clover HTML report and Clover statistics for a job: see Viewing the Clover code-coverage for a plan.

Clover code coverage summary for a plan: see Viewing the Clover code-coverage for a build.

Clover code coverage statistics across multiple plans: see Generating reports across multiple plans.

**Limit the machines that Clover runs on**

If you have more remote agents than the number of machines for which Clover is licensed, you can restrict the machines on which Clover runs by using capabilities:

1. For each of the EC2 images on which you would like to run builds with Clover, add a capability such as "clover=true" to the configuration for the image.
   
   To do this, go to Administration > Elastic Bamboo > Configuration. Select the elastic image and click Add Capability.

2. Now, add a matching requirement, such as "clover=true", to the configuration for each job.
   
   To do this, go to Actions > Configure Plan > Jobs. Select the job where Clover runs and click Requirements and then Add Extra Requirement.

**Troubleshooting**

**Automatic or manual Clover integration and spawned processes**

Using automatic Clover integration or adding a dependency to the maven-clover2-plugin manually is usually sufficient.

However, if your build spawns another JVM process (for example: unit tests executed in a forked JVM, tests in the container instantiated on the fly, tests calling code deployed on another server), you must manually add the dependency to the Clover JAR for these spawned processes.

See NoClassDefFoundError com_atlassian_clover/CoverageRecorder KB article.

**Automatic Clover integration and building in a subdirectory**

In case you perform a build in a subdirectory (for instance, in the Maven Task configuration you have the "Working sub directory" field set) and you have automatic Clover integration, you may need to correct the Location in the "Clover Report (System)" artifact. Otherwise, an HTML report may be empty as automatic Clover integration uses the default path (for instance, the "target/site/clover" in case of integration with Maven).

This issue has been fixed in Bamboo 5.7.

**Automatic Clover integration and multi-module Maven projects**

If you have a multi-module Maven project with dependencies between modules and use Automatic Clover integration, it can happen that an instrumented JAR of the dependent artifact will be taken for test execution in a build phase where Clover was not enabled yet. See BAM-13208 for more details. In such case, we recommend the following:

- create a separate Job in which automatic Clover integration is enabled
- create a Maven task in this job, which will do nothing (call the "clean" goal, for instance)
- Bamboo will automatically add Clover-related goals (clover2:setup verify clover2:aggregate clover2:clover)

This issue has been fixed in Bamboo 5.9.

**Clover Results Collector is unable to find the XML report file**
In the build log you may see a warning like:

Failed to execute plugin 'Clover Results Collector' with error: No file matches the specified pattern ...

The are several possible reasons, see this article for more details: Failed to execute plugin 'Clover Results Collector'.

Enabling the Clover add-on v6.1

This page describes how to enable and configure Atlassian's Clover add-on for a job in Bamboo.

When Bamboo is integrated with Clover, you can:

- View code-coverage details (i.e. the percentage of code covered by tests) for each build result
- View code-coverage trends for a job over a period of time
- View the code-coverage summary for the job.

On this page:

- Enable the Clover add-on
- Automatic Clover integration
- Manual Clover integration
- Browsing Clover results
- Limit the machines that Clover runs on
- Troubleshooting

Related pages:

- Viewing the Clover code-coverage for a build
- Viewing the Clover code-coverage for a plan
- Using Bamboo with Clover

Atlassian Blogs:

- Aggregated code coverage using Maven, Clover and Bamboo

Enable the Clover add-on

1. Navigate to the desired job, as described on Configuring jobs.
2. Choose Actions > Configure Job.
3. Click the Miscellaneous tab.
4. Select Use Clover to collect Code Coverage for this build and set the following:
   a. Automatically integrate Clover into this build
      You will need to provide a Clover license, unless this has been configured globally in the Administration panel (Administration > Plugins > Clover Plugin).
   b. Generate a Clover Historical Report
      Displays the current coverage results compared with previous Clover code coverage reports.
   c. Generate a JSON report
      Provides the Clover results in a format ready for embedding into applications or external report views.
   d. Use plan-defined Clover license key
      Override the global Clover license for this particular plan.
   e. Clover is already integrated into this build
      Use this option when you already have Clover-for-Ant, Clover-for-Maven or another Clover integration configured to generate a report.
   f. Clover XML Location
      Specify the location where Bamboo will look for the XML report file from Clover. Please specify the file path relative to your plan's root directory (e.g. /home/bamboouser/bamboo-home/xml-data/build-dir/MY_PLAN/), i.e. do not specify an absolute path.

Screenshot: Settings to enable Clover for a job:
Automatic Clover integration

Automatic integration works with Ant, Maven 2.x, Maven 3.x and Grails tasks:

1. Check **Use Clover to collect Code Coverage for this build** in the Clover Code Coverage settings.
2. Select **Automatically integrate Clover into this build**.
3. Enter the global license key for Clover (go to Administration > Plugins > Clover Plugin), or enable **Use plan-defined Clover license key** and paste the key into the text field that appears.

Additionally, you can:

- Select **Generate a Clover Historical Report** to compare the current coverage results with previous Clover code coverage reports.
- Select **Generate a JSON report** to get the Clover results in a format ready for embedding into applications or external report views.

What happens during automatic integration...

As Clover integration (automatic and manual) produces instrumented classes, we recommend that you ensure that your job does not install them to production (for instance: 'mvn deploy' to public repository, 'scp' to an application server running on production, etc ...). Having instrumented code in such locations is usually not desired.

Common practices to ensure proper separation of instrumented and non-instrumented classes are:

- create a dedicated plan or job with Clover integration enabled
- enable automatic Clover integration for jobs running tests only (e.g. "mvn verify")
- use different location of local artifact cache if you need to install artifacts (e.g. ~/.m2/repository-clover and "mvn install")
- use different URL for uploading artifacts if necessary (e.g. a separate repository for "mvn deploy")
When automatic Clover integration is enabled, Bamboo:

- Creates an artifact named **Clover Report (System)**, which is visible on the 'Artifacts' tab for the job.

and during every build:

- Extracts the Clover license (either the global or plan license key) into a temporary file and passes it to:
  - an Ant task as `-Dclover.license.path=<bamboo-home>/xml-data/build-dir/<your-job>/clover/clover.license`
  - a Maven task as `-Dmaven.clover.licenseLocation=<bamboo-home>/xml-data/build-dir/<your-job>/clover/clover.license`
- Enhances tasks by adding
  - Ant - targets like "with.clover", "clover:report"
  - Maven - goals like "clover2:setup", "clover2:aggregate", "clover2:clover", "clover2:save-history"; it also adds "verify" phase if original command does not call "compile" or later phase
  - Grails - options like "-clover"
- Generates Clover XML and HTML reports (by default)
- Generates statistics and charts for a plan summary

In order to protect you against publishing instrumented code, automatic Clover integration will not run if the Maven task runs the "install" or "deploy" phases. In such case, you will find no Clover report and a build log will contain an appropriate warning message. In order to get coverage reports for such job, either edit the Maven task to run the build till the "verify" phase (or earlier) or configure Clover manually.

**Manual Clover integration**

Manual Clover integration works with any kind of task in which Clover can be called (Ant, Maven 2.x, Maven 3.x, Command, Grails).

1. Check Use Clover to collect Code Coverage for this build, in the Clover Code Coverage settings.
2. Check Clover is already integrated into this build ...
3. Specify in Clover XML Location where Bamboo will look for the XML report file generated by Clover.
4. On the 'Artifacts' tab, click Create Definition and complete the form as follows:

   **Name**
   This should begin with "Clover Report".

   **Location**
   This should point to the HTML report directory (e.g. target/site/clover)

   **Copy Pattern**
   Use "**/.*"

5. Configure Clover in your build script so that it generates both XML and HTML reports.

   **Example for Ant...**

   ```xml
   <clover-report initstring="target/clover/database/clover.db">
     <current outfile="target/site/clover/clover.xml" />
     <current outfile="target/site/clover" />
     <format type="html"/>
   </current>
   </clover-report>
   ``

   **Example for Maven...**
6. Configure the Clover license in your build script or pass it as a proper task parameter in the job configuration:
   a. Save the Clover license key in a file (for example in /opt/bamboo/clover.license).
   b. Pass the location of the license key to the build task:
      • Define it in the build script, or
      • Pass it as a Java property for the Ant/Maven task in the plan configuration.

   **How to declare the license location in pom.xml...**

- Bamboo will automatically add Clover-related goals (clover2:setup verify clover2:aggregate clover2:clover)

This issue has been fixed in Bamboo 5.9.

**Clover Results Collector is unable to find the XML report file**
In the build log you may see a warning like:

```
Failed to execute plugin 'Clover Results Collector' with error: No file matches the specified pattern ...
```

The are several possible reasons, see this article for more details: Failed to execute plugin 'Clover Results Collector'.

### Enabling the Clover add-on v6.2

This page describes how to enable and configure Atlassian's Clover add-on for a job in Bamboo.

When Bamboo is integrated with Clover, you can:

- View code-coverage details (i.e. the percentage of code covered by tests) for each build result
- View code-coverage trends for a job over a period of time
- View the code-coverage summary for the job.

On this page:
- Enable the Clover add-on
- Automatic Clover integration
- Manual Clover integration
- Browsing Clover results
- Limit the machines that Clover runs on
- Troubleshooting

#### Related pages:

- Viewing the Clover code-coverage for a build
- Viewing the Clover code-coverage for a plan

#### Atlassian Blogs:

- Aggregated code coverage using Maven, Clover and Bamboo

### Enable the Clover add-on

1. Navigate to the desired job, as described on Configuring jobs.
2. Choose Actions > Configure Job.
3. Click the Miscellaneous tab.
4. Select **Use Clover to collect Code Coverage for this build** and set the following:
   a. **Automatically integrate Clover into this build**
      You will need to provide a Clover license, unless this has been configured globally in the Administration panel (Administration > Plugins > Clover Plugin).
   b. **Generate a Clover Historical Report**
      Displays the current coverage results compared with previous Clover code coverage reports.
   c. **Generate a JSON report**
      Provides the Clover results in a format ready for embedding into applications or external report views.
   d. **Use plan-defined Clover license key**
      Override the global Clover license for this particular plan.
   e. **Clover is already integrated into this build**
      Use this option when you already have Clover-for-Ant, Clover-for-Maven or another Clover integration configured to generate a report.
   f. **Clover XML Location**
      Specify the location where Bamboo will look for the XML report file from Clover. Please specify the file path relative to your plan's root directory (e.g. /home/bamboouser/bamboo-home/xml-data/build-dir/MY_PLAN/), i.e. do not specify an absolute path.

```
(target/site/clover/clover.xml)
```

### Screenshot: Settings to enable Clover for a job:
Automatic Clover integration

Automatic integration works with Ant, Maven 2.x, Maven 3.x and Grails tasks:

1. Check **Use Clover to collect Code Coverage for this build** in the Clover Code Coverage settings.
2. Select **Automatically integrate Clover into this build**.
3. Enter the global license key for Clover (go to Administration > Plugins > Clover Plugin), or enable **Use plan-defined Clover license key** and paste the key into the text field that appears.

Additionally, you can:

- Select **Generate a Clover Historical Report** to compare the current coverage results with previous Clover code coverage reports.
- Select **Generate a JSON report** to get the Clover results in a format ready for embedding into applications or external report views.

What happens during automatic integration...

As Clover integration (automatic and manual) produces instrumented classes, we recommend that you ensure that your job does not install them to production (for instance: ‘mvn deploy’ to public repository, ‘scp’ to an application server running on production, etc ...). Having instrumented code in such locations is usually not desired.

Common practices to ensure proper separation of instrumented and non-instrumented classes are:

- create a dedicated plan or job with Clover integration enabled
- enable automatic Clover integration for jobs running tests only (e.g. "mvn verify")
- use different location of local artifact cache if you need to install artifacts (e.g. ~/.m2/repository-clover and "mvn install")
- use different URL for uploading artifacts if necessary (e.g. a separate repository for "mvn deploy")
When automatic Clover integration is enabled, Bamboo:

- Creates an artifact named **Clover Report (System)**, which is visible on the 'Artifacts' tab for the job.

and during every build:

- Extracts the Clover license (either the global or plan license key) into a temporary file and passes it to:
  - an Ant task as `-Dclover.license.path=<bamboo-home>/xml-data/build-dir/<your-job>/clover/clover.license`
  - a Maven task as `-Dmaven.clover.licenseLocation=<bamboo-home>/xml-data/build-dir/<your-job>/clover/clover.license`
- Enhances tasks by adding
  - Ant - targets like "with.clover", "clover:report"
  - Maven - goals like "clover:setup", "clover:aggregate", "clover2:clover", "clover2:save-history"; it also adds "verify" phase if original command does not call "compile" or later phase
  - Grails - options like "-clover.on"
- Generates Clover XML and HTML reports (by default)
- Generates statistics and charts for a plan summary

In order to protect you against publishing instrumented code, automatic Clover integration will **not** run if the Maven task runs the "install" or "deploy" phases. In such case, you will find no Clover report and a build log will contain an appropriate warning message. In order to get coverage reports for such job, either edit the Maven task to run the build till the "verify" phase (or earlier) or configure Clover manually.

## Manual Clover integration

Manual Clover integration works with any kind of task in which Clover can be called (Ant, Maven 2.x, Maven 3.x, Command, Grails).

1. Check **Use Clover to collect Code Coverage for this build**, in the Clover Code Coverage settings.
2. Check **Clover is already integrated into this build**.
3. Specify in **Clover XML Location** where Bamboo will look for the XML report file generated by Clover.
4. On the 'Artifacts' tab, click **Create Definition** and complete the form as follows:

   **Name**
   
   This should begin with with "Clover Report".

   **Location**
   
   This should point to the HTML report directory (e.g. target/site/clover)

   **Copy Pattern**
   
   Use "**/.*".

5. Configure Clover in your build script so that it generates both XML and HTML reports.

   **Example for Ant...**
   ```xml
   <clover-report initstring="target/clover/database/clover.db">
     <current outfile="target/site/clover/clover.xml" />
     <current outfile="target/site/clover" />
     <format type="html" />
   </current>
   </clover-report>
   ```

   **Example for Maven...**
6. Configure the Clover license in your build script or pass it as a proper task parameter in the job configuration:
   a. Save the Clover license key in a file (for example in /opt/bamboo/clover.license).
   b. Pass the location of the license key to the build task:
      • Define it in the build script, or
      • Pass it as a Java property for the Ant/Maven task in the plan configuration.

   **How to declare the license location in pom.xml...**

   ```xml
   <plugin>
     <groupId>com.atlassian.maven.plugins</groupId>
     <artifactId>maven-clover2-plugin</artifactId>
     <version>3.1.8</version>
     <configuration>
       <licenseLocation>/opt/bamboo/clover.license</licenseLocation>
       <generateXml>true</generateXml>
       <generateHtml>true</generateHtml>
     </configuration>
   </plugin>
   ```

   **How to declare the license location in build.xml...**

   ```xml
   <project>
     <property name="clover.license.path" location="/opt/bamboo/clover.license"/>
   </project>
   ```

   **How to pass the license location for Ant...**

   ```
   clean with.clover test clover.report
   -Dclover.license.path=/opt/bamboo/clover.license
   ```

   **How to pass the license location for Maven...**

   ```
   mvn clean clover2:setup verify clover2:aggregate clover2:clover
   -Dmaven.clover.licenseLocation=/opt/bamboo/clover.license
   ```
After every build, Bamboo will parse the Clover XML file and generate statistics and charts for a plan summary. The Plan summary and job summary pages will contain a "Clover" tab.

**Browsing Clover results**

Clover HTML report and Clover statistics for a job: see Viewing the Clover code-coverage for a plan.

Clover code coverage summary for a plan: see Viewing the Clover code-coverage for a build.

Clover code coverage statistics across multiple plans: see Generating reports across multiple plans.

**Limit the machines that Clover runs on**

If you have more remote agents than the number of machines for which Clover is licensed, you can restrict the machines on which Clover runs by using capabilities:

1. For each of the EC2 images on which you would like to run builds with Clover, add a capability such as "clover=true" to the configuration for the image. To do this, go to Administration > Elastic Bamboo > Configuration. Select the elastic image and click Add Capability.
2. Now, add a matching requirement, such as "clover=true", to the configuration for each job. To do this, go to Actions > Configure Plan > Jobs. Select the job where Clover runs and click Requirements and then Add Extra Requirement.

**Troubleshooting**

**Automatic or manual Clover integration and spawned processes**

Using automatic Clover integration or adding a dependency to the maven-clover2-plugin manually is usually sufficient.

However, if your build spawns another JVM process (for example: unit tests executed in a forked JVM, tests in the container instantiated on the fly, tests calling code deployed on another server), you must manually add the dependency to the Clover JAR for these spawned processes.

See NoClassDefFoundError com_atlassian_clover/CoverageRecorder KB article.

**Automatic Clover integration and building in a subdirectory**

In case you perform a build in a subdirectory (for instance, in the Maven Task configuration you have the "Working sub directory" field set) and you have automatic Clover integration, you may need to correct the Location in the "Clover Report (System)" artifact. Otherwise, an HTML report may be empty as automatic Clover integration uses the default path (for instance, the "target/site/clover" in case of integration with Maven).

This issue has been fixed in Bamboo 5.7.

**Automatic Clover integration and multi-module Maven projects**

If you have a multi-module Maven project with dependencies between modules and use Automatic Clover integration, it can happen that an instrumented JAR of the dependent artifact will be taken for test execution in a build phase where Clover was not enabled yet. See BAM-132 08 for more details. In such case, we recommend the following:

- create a separate Job in which automatic Clover integration is enabled
- create a Maven task in this job, which will do nothing (call the "clean" goal, for instance)
- Bamboo will automatically add Clover-related goals (clover2:setup verify clover2:aggregate clover2:clover)

This issue has been fixed in Bamboo 5.9.

**Clover Results Collector is unable to find the XML report file**
In the build log you may see a warning like:

Failed to execute plugin 'Clover Results Collector' with error: No file matches the specified pattern

... 

The are several possible reasons, see this article for more details: Failed to execute plugin 'Clover Results Collector'.

Data and backups

For information on managing data and backups, see the following topics:

- Locating important directories and files
- Specifying Bamboo’s working directory
- Reindexing data
- Specifying a backup schedule
- Exporting data for backup
- Importing data from backup
- Configuring global expiry
- Importing data from Jenkins
- Plan directory information REST API

Locating important directories and files

The information on this page describes how to find important Bamboo directories and files.

On this page:

- Bamboo server installation directory
- Bamboo server home directory
- Bamboo agent home directory

Bamboo server installation directory

When you installed your Bamboo server, you specified the location for the Bamboo installation directory — this is the directory where the Bamboo application files are installed. (The default location depends on your operating system: Windows, Unix/Linux, Solaris or Mac OS.)

atlassian-bamboo/WEB-INF/classes/bamboo-init.properties

This file tells Bamboo where to find the Bamboo home directory. The location of this directory is specified by the Bamboo administrator as described in the Bamboo installation guide.

See Starting Bamboo.

bin/start-bamboo.sh

This is the startup file for Bamboo under Unix/Linux, Solaris and Mac OS.

bin/start-bamboo.bat

This is the startup file for the Bamboo under Windows.

scripts/Triggers

This directory contains operational scripts (used when configuring the repository to trigger a Bamboo build).

logs/*

This directory contains logs unless you have used the Installer for Windows. (Note: The Bamboo server logs are written to the root of the installation directory. Build logs are stored in the <BambooHome>/xml-data/builds/ sub-directories.)

⚠️ If you used the Installer for Windows, log files will be located at %USERPROFILE%\bamboo.log. For Bamboo running as a Windows service it can be found at %WINDIR%\System32\Config\systemprofile\bamboo.log.

atlassian-bamboo/WEB-INF/lib/

This directory is used when deploying Bamboo add-ons. It also contains other libraries required by Bamboo.

atlassian-bamboo/WEB-INF/classes/log4j.properties

This is Bamboo’s logging configuration file. Also the logging can be configured from the Bamboo UI by navigating to Administration -> Log Settings page, but the changes made on that page will be reverted by a Bamboo restart; however, changes made in the log4j.properties file will stay even if Bamboo gets restarted.

Bamboo server home directory
When you installed your Bamboo server, you specified the location for the *Bamboo home directory* — this is the directory where your Bamboo configuration data and build results are stored. (The default location depends on your operating system: Windows, Unix/Linux, Solaris or Mac OS.) This directory can grow quite large when managing large quantities of plans and builds.

The structure of the home directory will change in an upcoming Bamboo release, potentially breaking any tools or scripts that rely on the current structure. You can future-proof your tools by using the Plan directory information REST API.

When you installed your Bamboo server, you specified the location for the *Bamboo home directory* — this is the directory where your Bamboo configuration data and build results are stored. (The default location depends on your operating system: Windows, Unix/Linux, Solaris or Mac OS.) This directory can grow quite large when managing large quantities of plans and builds.

The structure of the home directory will change in an upcoming Bamboo release, potentially breaking any tools or scripts that rely on the current structure. You can future-proof your tools by using the Plan directory information REST API.

- **artifacts/** is a folder shared by all the stages of a certain plan. Stages will place Artifacts here so that other stages from the same plan can have access to them. The BUILD_NUMBER will always have a minimum of 5 digits, having the number completed with zeros when necessary. For instance, for build “42” the number will be “00042”.
- **bamboo.cfg.xml**
  This is Bamboo's core configuration file. It includes the configuration information for connecting to Bamboo's database.
- **xml-data/**
  This directory contains all files relating to source repositories and build results.
- **xml-data/build-dir/**
  This is known as the *Working Directory*. This is where Bamboo temporarily puts the checked-out files it is building. The location of this directory can be changed as described in Specifying Bamboo's Working Directory.
- **xml-data/builds/**
  This is known as the *Build Directory*. This is where Bamboo stores build results (note that they will be deleted as described in Configuring global expiry). Its contents can be backed up as per Exporting data for backup.
- **xml-data/builds/**
  Contains the build results for all the builds belonging to the JOB_KEY plan. Each build result is an individual XML file. Do not edit these files or the corresponding information in the database may become corrupt.
- **xml-data/builds/**
  Contains the logs for each build belonging to the JOB_KEY plan.
- **xml-data/configuration/**
  This is known as the *Configuration Directory*. It contains server-wide configuration information. Its contents can be backed up as per Exporting data for backup.
- **database/**
  This directory contains Bamboo's embedded H2 database. The database contains plan configurations and some build results data. This directory is not present if an external database is used instead of the embedded H2.

  **i** H2 is not recommended for production Bamboo instances.
- **index/**
  This directory contains the build results index. Removing or modifying files in this directory may corrupt build history. Rebuilding the search index from Bamboo's global administration screen (see Reindexing data) will completely regenerate the contents of this directory.
- **logs/**
  Bamboo server home directory:
  This directory contains logs unless you have used the *Installer for Windows*. (Note: The Bamboo server logs are written to the root of the installation directory. Build logs are stored in the xml-data/builds/ sub-directories.)

  **i** If you used the Installer for Windows, log files will be located at `%USERPROFILE%\bamboo.log`. For Bamboo running as a Windows service it can be found at `%WINDIR%\System32\Config\systemprofile\bamboo.log`.

When you installed your remote agents (if any), you specified the location for the *Agent home directory* — this is the directory where the agent's configuration data is stored. The default name of this directory is bamboo-agent-home. This directory can grow quite large when managing large numbers of plans and builds. The default bamboo-agent-home location depends on your operating system: Windows, Unix/Linux, Solaris or Mac OS.

The contents of the agent home directory are:

- **bamboo-agent.cfg.xml**
  This contains configuration information about this remote agent. Most notably, it stores the agent id, which gets generated the first time this agent connects to the Bamboo server.
- **xml-data/build-dir/**
  This is where the agent will check out the files and perform builds (similar to the Bamboo server's xml-data/build-dir/ directory)

**Locating important directories and files v5.14**
The information on this page describes how to find important Bamboo directories and files.

**Bamboo agent home directory**

When you installed your remote agents (if any), you specified the location for the agent home directory — this is the directory where the agent's configuration data is stored. The default name of this directory is `~/.bamboo-agent-home`. This directory can grow quite large when managing large numbers of plans and builds. The default location depends on your operating system: Windows, Unix/Linux, Solaris or Mac OS.

The contents of the agent home directory are:

- bamboo-agent.cfg.xml This contains configuration information about this remote agent. Most notably, it stores the agent id, which gets generated the first time this agent connects to the Bamboo server.

- xml-data/build-dir/ This is where the agent will check out the files and perform builds (similar to the Bamboo server's xml-data/build-dir/directory)

**Locating important directories and files v6.1**

The information on this page describes how to find important Bamboo directories and files.

**Bamboo server installation directory**

When you installed your Bamboo server, you specified the location for the Bamboo installation directory — this is the directory where the Bamboo application files are installed. (The default location depends on your operating system: Windows, Unix/Linux, Solaris or Mac OS.)

- atlassian-bamboo/WEB-INF/classes/bamboo-init.properties This file tells Bamboo where to find the Bamboo home directory. The location of this directory is specified by the Bamboo administrator as described in the Bamboo installation guide.

See Starting Bamboo.
### bin/start-bamboo.sh
This is the startup file for Bamboo under Unix/Linux, Solaris and Mac OS.

### bin/start-bamboo.bat
This is the startup file for the Bamboo under Windows.

### scripts/Triggers
This directory contains operational scripts (used when configuring the repository to trigger a Bamboo build).

### logs/*
This directory contains logs unless you have used the Installer for Windows. (Note: The Bamboo server logs are written to the root of the installation directory. Build logs are stored in the `<BambooHome>/xml-data/builds/` sub-directories.)

⚠️ If you used the Installer for Windows, log files will be located at `%USERPROFILE%\bamboo.log`. For Bamboo running as a Windows service it can be found at `%WINDIR%\System32\Config\systemprofile\bamboo.log`.

### atlassian-bamboo/WEB-INF/lib/
This directory is used when deploying Bamboo add-ons. It also contains other libraries required by Bamboo.

Bamboo server home directory

When you installed your Bamboo server, you specified the location for the Bamboo home directory — This is the directory where your
Bamboo configuration data and build results are stored. (The default location depends on your operating system: Windows, Unix/Linux, Solaris or Mac OS.) This directory can grow quite large when managing large quantities of plans and builds.

The structure of the home directory will change in an upcoming Bamboo release, potentially breaking any tools or scripts that rely on the current structure. You can future-proof your tools by using the Plan directory information REST API.

artifacts/PLAN_KEY/shared/build-BUILD_NUMBER/
This is a folder shared by all the stages of a certain plan. Stages will place Artifacts here so that other stages from the same plan can have access to them. The BUILD_NUMBER will always have a minimum of 5 digits, having the number completed with zeros when necessary. For instance, for build “42” the number will be “00042”.

bamboo.cfg.xml
This is Bamboo’s core configuration file. It includes the configuration information for connecting to Bamboo’s database.

xml-data/
This directory contains all files relating to source repositories and build results.

xml-data/build-dir/JOB_KEY
This is known as the Working Directory. This is where Bamboo temporarily puts the checked-out files it is building. The location of this directory can be changed as described in Specifying Bamboo’s Working Directory.

xml-data/builds/
This is known as the Build Directory. This is where Bamboo stores build results (note that they will be deleted as described in Configuring global expiry). Its contents can be backed up as per Exporting data for backup.

xml-data/builds/JOB_KEY/results
Contains the build results for all the builds belonging to the JOB_KEY plan. Each build result is an individual XML file. Do not edit these files or the corresponding information in the database may become corrupt.

xml-data/builds/JOB_KEY/download-data
Contains the logs for each build belonging to the JOB_KEY plan.

xml-data/configuration/
This is known as the Configuration Directory. It contains server-wide configuration information. Its contents can be backed up as per Exporting data for backup.

database/
This directory contains Bamboo’s embedded H2 database. The database contains plan configurations and some build results data. This directory is not present if an external database is used instead of the embedded H2.

index/
This directory contains the build results index. Removing or modifying files in this directory may corrupt build history. Rebuilding the search index from Bamboo’s global administration screen (see Reindexing data) will completely regenerate the contents of this directory.

logs/*
Bamboo server home directory:
This directory contains logs unless you have used the Installer for Windows. (Note: The Bamboo server logs are written to the root of the installation directory. Build logs are stored in the xml-data/builds/sub-directories.)

If you used the Installer for Windows, log files will be located at %USERPROFILE%\bamboo.log. For Bamboo running as a Windows service it can be found at %WINDIR%\System32\Config\systemprofile\bamboo.log.

Bamboo agent home directory
When you installed your remote agents (if any), you specified the location for the Agent home directory — this is the directory where the agent’s configuration data is stored. The default name of this directory is bamboo-agent-home. This directory can grow quite large when managing large numbers of plans and builds. The default bamboo-agent-home location depends on your operating system: Windows, Unix/Linux, Solaris or Mac OS.

The contents of the agent home directory are:

bamboo-agent.cfg.xml
This contains configuration information about this remote agent. Most notably, it stores the agent id, which gets generated the first time this agent connects to the Bamboo server.

xml-data/build-dir/
This is where the agent will check out the files and perform builds (similar to the Bamboo server’s xml-data/build-dir/ directory)

Specifying Bamboo’s working directory
The Working Directory is where Bamboo temporarily puts the checked-out files it is building. The location of this directory was specified using the Setup Wizard, can be viewed as described in Bamboo’s system information, and can be changed as described below.
By default, this directory is located under the xml-data directory in the Bamboo home directory.

Each build's jobs have their own working directory relative to this configured working directory:

xml-data/build-dir/JOB_KEY

If Concurrent Builds are enabled, local agent builds will use the format:

xml-data/build-dir/AGENT_ID/JOB_KEY

To change the location of Bamboo's working directory:

1. Shut down Bamboo.
2. Open the `<Bamboo-Home>/bamboo.cfg.xml` file in a text editor. Find the following line -

   ....
   <property
   name="buildWorkingDir">/home/Bamboo-home/xml-data/build-dir</property>
   ....

3. Edit the Bamboo working directory to point to a new folder on disk.
4. Save the changes and restart Bamboo.

   Note: Bamboo will do a fresh checkout and perform a clean build of all your plans, once the directory is changed.

Specifying Bamboo's working directory v5.14

The Working Directory is where Bamboo temporarily puts the checked-out files it is building. The location of this directory was specified using the Setup Wizard, can be viewed as described in Bamboo's system information, and can be changed as described below.

By default, this directory is located under the xml-data directory in the Bamboo home directory.

Each build's jobs have their own working directory relative to this configured working directory:

xml-data/build-dir/JOB_KEY

To change the location of Bamboo's working directory:

1. Shut down Bamboo.
2. Open the `<Bamboo-Home>/bamboo.cfg.xml` file in a text editor. Find the following line -

   ....
   <property
   name="buildWorkingDir">/home/Bamboo-home/xml-data/build-dir</property>
   ....

3. Edit the Bamboo working directory to point to a new folder on disk.
4. Save the changes and restart Bamboo.

   Note: Bamboo will do a fresh checkout and perform a clean build of all your plans, once the directory is changed.

Specifying Bamboo's working directory v5.15

The Working Directory is where Bamboo temporarily puts the checked-out files it is building. The location of this directory was specified using the Setup Wizard, can be viewed as described in Bamboo's system information, and can be changed as described below.

By default, this directory is located under the xml-data directory in the Bamboo home directory.

Each build's jobs have their own working directory relative to this configured working directory:

xml-data/build-dir/JOB_KEY

If Concurrent Builds are enabled, local agent builds will use the format:

xml-data/build-dir/AGENT_ID/JOB_KEY

To change the location of Bamboo's working directory:
1. Shut down Bamboo.
2. Open the `<Bamboo-Home>/bamboo.cfg.xml` file in a text editor. Find the following line:

   ```xml
   <property name="buildWorkingDir">/home/Bamboo-home/xml-data/build-dir</property>
   ```

3. Edit the Bamboo working directory to point to a new folder on disk.
4. Save the changes and restart Bamboo.
   *Note: Bamboo will do a fresh checkout and perform a clean build of all your plans, once the directory is changed.*

### Reindexing data

**About re-indexing**

You will need to re-index your Bamboo build results data whenever you perform a data import. Re-indexing your data can also be helpful if your reports appear to be out-of-sync with your data. This may take a few minutes to complete (see System settings for an estimate of how long it will take).

**Related pages:**

- Data and backups

**To re-index Bamboo's build results data:**

1. Click the 
   ![icon](image.png) in the Bamboo header and choose Overview.
2. Click Indexing in the left navigation column, under 'System'.
3. Click Perform a full reindex.

### Reindexing data v5.14

**About re-indexing**

You will need to re-index your Bamboo build results data whenever you perform a data import. Re-indexing your data can also be helpful if your reports appear to be out-of-sync with your data. This may take a few minutes to complete (see System settings for an estimate of how long it will take).

**Related pages:**

- Data and backups

**To re-index Bamboo's build results data:**

1. Click the 
   ![icon](image.png) in the Bamboo header and choose Overview.
2. Click Indexing in the left navigation column, under 'System'.
3. Click Perform a full reindex.

### Specifying a backup schedule

You can configure Bamboo to automatically create a backup each night, rather than doing a manual export every time.

**Before you begin,**

- Bamboo will be unavailable while the backup process completes. The export itself may take a long time to complete, depending on the number of builds and tests. We recommend running your backups at a time of day or night when usage is low.
- Backups may require large amounts of disk space, depending on the number of builds and tests. Please make sure you have enough disk space in your desired backup location before proceeding.
- Bamboo will not export if plans are currently being built (see Using the Bamboo dashboard).

**For large instances we recommend using native database and filesystem backup tools instead of the built in backup/export functionality. For more details, see Automating Bamboo backup operations. Reserve the use of the built-in tools for database type migrations only (e.g. MySQL to Postgre).**

**On this page:**

- Specifying a backup schedule
- Disabling a backup
Specifying a backup schedule

To specify a backup schedule:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Scheduled Backups in the left navigation column (under ‘System’).
3. Click Edit to modify the schedule settings:
   - **Disable scheduled backups**
     This check box must be cleared for automatic backups to be performed.
   - **Backup Artifacts**
     Select if you want to include build artifacts in your scheduled backups.
   - **Backup path**
     Specify the directory where you want to store your backups. Each backup will be stored as a single file. It may be necessary to modify the Bamboo bamboo.paths.set.allowed system property to do this.
     
     **Note that:**
     Bamboo restricts the editing of certain file path settings for security reasons (see Bamboo Security Advisory 2010-05-04). If you must configure Bamboo to permit modification to its file path settings, start Bamboo with the system property bamboo.paths.set.allowed=true. The procedure for configuring a Bamboo system property is described on Starting Bamboo.
     
     Once you have configured your file path setting, we recommend removing or disabling the bamboo.paths.set.allowed system property and restarting Bamboo. If your Bamboo instance is accessible to anyone outside your organization, then this will minimize the risk of Bamboo being compromised by security-related attacks.

   - **Backup file prefix**
     Specify the first part of the filename for all your backup files.

   - **Backup file date pattern**
     Specify the date/time format for identifying your individual backup files. This will be appended to **Backup file prefix** to form the complete filename for your backup files.

   - **Schedule**
     Use the Schedule Editor to choose the frequency with which backups will be performed. See Cron-based scheduling for more information about the Schedule Editor.

4. Click Save. Your first backup will run when your server's clock matches the specified time.

Disabling a backup

If you disable schedule backups, your schedule details will be retained but no automatic backups will be performed.

To disable a scheduled backup:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Scheduled Backups in the left navigation column. The ‘Scheduled Backup Details’ page will be displayed, showing details about the status of scheduled backups or any currently configured backup.
3. Click Edit to edit the current ‘Scheduled Backup Details’.
4. Select the **Disable scheduled backups** check box.
5. Click Save.
You can configure Bamboo to automatically create a backup each night, rather than doing a manual export every time.

Before you begin,

- Bamboo will be unavailable while the backup process completes. The export itself may take a long time to complete, depending on the number of builds and test. We recommend running your backups at a time of day or night when usage is low.
- Backups may require large amounts of disk space, depending on the number of builds and tests. Please make sure you have enough disk space in your desired backup location before proceeding.
- Bamboo will not export if plans are currently being built (see Using the Bamboo dashboard).

5. Click Save.
Exporting data for backup

The instructions on this page describe how to export Bamboo data for backup.

Before you begin:

- Bamboo will be unavailable while the backup process completes. The export itself may take a long time to complete, depending on the number of builds and tests. We recommend running your backups at a time of day or night when usage is low.
- Backups may require large amounts of disk space, depending on the number of builds and tests. Please make sure you have enough disk space in your desired backup location before proceeding.
- Bamboo will not export if plans are currently being built.
- User management settings for Bamboo will be saved as part of the export. For information on user management in Bamboo, see Connecting to external user directories.
- Export Directory Path setting: Bamboo restricts the editing of certain file path settings for security reasons (see Bamboo Security Advisory 2010-05-04). If you must configure Bamboo to permit modification to its file path settings, start Bamboo with the system property bamboo.paths.set.allowed=true. The procedure for configuring a Bamboo system property is described on Starting Bamboo. Once you have configured your file path setting, we recommend removing or disabling the bamboo.paths.set.allowed system property and restarting Bamboo. If your Bamboo instance is accessible to anyone outside your organization, then this will minimize the risk of Bamboo being compromised by security-related attacks.

For large instances we recommend using native database and filesystem backup tools instead of the built in backup/export functionality. For more details, see Automating Bamboo backup operations. Reserve the use of the built-in tools for database type migrations only (e.g. MySQL to Postgre).

To export data for backup:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Export in the left navigation column (under 'System').
3. Complete the following settings:

   **Export Directory Path**
   This can be configured – see the note above.

   **File Name**
   Edit the default name of the file to which Bamboo will export, if necessary.

   **Export Results**
   Clear this to export only the plan configurations.

   **Export Artifacts**
Select to have Bamboo export build artifacts.

**Export Build Logs**
Select to have Bamboo export build logs.

4. Click the **Export**. Bamboo creates the export file in the location shown for **Export Directory Path**.

---

Exporting data for backup v5.14

**Importing data from backup**

The instructions on this page describe how to import data from a Bamboo backup.

**Before you begin:**

- Bamboo will be unavailable until the import process is complete, which may take some time.
- The import process will delete your Bamboo installation and restore data from a previous export of Bamboo. This includes login data, so you will need to know an administration login in the Bamboo data to be imported.

- If you created your backup file using Bamboo 3.2 or later, importing the file will restore your user management settings. If you created your backup file using Bamboo 3.1 or earlier, importing the file will default your user management settings to 'Local users and groups' (i.e. user/group management in Bamboo). You may need to change your settings after the import.

- If you manage users externally (using LDAP or Crowd) and the Bamboo internal user repository (in the backup file) contains user names that duplicate user names in the external repository, you will not be able to import from the backup file.

**Backup Directory Path:** Bamboo restricts the editing of certain file path settings for security reasons (see Bamboo Security Advisory 2010-05-04). If you must configure Bamboo to permit modification to its file path settings, start Bamboo with the system property `bamboo.paths.set.allowed=true`. The procedure for configuring a Bamboo system property is described on Starting Bamboo.

Once you have configured your file path setting, we recommend removing or disabling the `bamboo.paths.set.allowed` system property and restarting Bamboo. If your Bamboo instance is accessible to anyone outside your organization, then this will minimize the risk of Bamboo being compromised by security-related attacks.

4. Click Import.
5. After the import is complete,
   - check the paths of your builders and JDK.
   - index your data.

Importing data from backup v6.1

The instructions on this page describe how to import data from a Bamboo backup.

Before you begin:

- **Bamboo will be unavailable until the import process is complete, which may take some time.**
- **The import process will delete your Bamboo installation and restore data from a previous export of Bamboo. This includes login data, so you will need to know an administration login in the Bamboo data to be imported.**
- **If you created your backup file using Bamboo 3.2 or later, importing the file will restore your user management settings.**
created your backup file using Bamboo 3.1 or earlier, importing the file will default your user management settings to ‘Local users and groups’ (i.e. user/group management in Bamboo). You may need to change your settings after the import.

- If you manage users externally (using LDAP or Crowd) and the Bamboo internal user repository (in the backup file) contains user names that duplicate user names in the external repository, you will not be able to import from the backup file.
- **Backup Directory Path**: Bamboo restricts the editing of certain file path settings for security reasons (see Bamboo Security Advisory 2010-05-04). If you must configure Bamboo to permit modification to its file path settings, start Bamboo with the system property `bamboo.paths.set.allowed=true`. The procedure for configuring a Bamboo system property is described on Starting Bamboo.

Once you have configured your file path setting, we recommend removing or disabling the `bamboo.paths.set.allowed` system property and restarting Bamboo. If your Bamboo instance is accessible to anyone outside your organization, then this will minimize the risk of Bamboo being compromised by security-related attacks.

- Data and backups
- Specifying a backup schedule
- Exporting data for backup

### To import data from backup:

1. Click the icon in the Bamboo header and choose **Overview**.
2. Click **Import** in the left navigation column (under ‘System’).
3. Complete the following settings:
   - **File Path**
     The absolute path to the data file that Bamboo should import. For example, "/opt/bamboo/bamboo-home/export.zip" on UNIX-based operating systems.
   - **Backup data**
     *Highly recommended.* Bamboo will not import data unless it is able to successfully export data first.
   - **Backup Directory Path**
     This can be configured – see the note above.
   - **File Name**
     The file to which Bamboo will export its data.
   - **Clear artifact directory**
     Delete all existing build artifacts before the import.
   - **Apply imported data without server shutdown**
     *Not recommended in a production environment.*
4. Click **Import**.
5. After the import is complete,
   - check the paths of your builders and JDK.
   - index your data.
Configuring global expiry

Global expiry allows you to manage the timing for when build and deployment artifacts should be deleted from your Bamboo system.

You may want to consider doing this for the following reasons:

- Build and deployment artifacts can be large, and so consume storage on your system. Your system may run out of disk space if artifacts no longer in active use are retained indefinitely.
- Large numbers of builds and deployments clutter the Bamboo user interface, and may reduce performance, making it slower to work with Bamboo.

See this Atlassian blog post for a discussion of using build expiry and labels.

Global expiry applies to all build plans and deployment projects, and is generally the easiest way to manage artifacts expiry in Bamboo.

However, note that:

- You can configure build expiry for individual build plans to override the global expiry settings. You can not yet override the global expiry configuration for particular deployment projects.
- You can also delete the results of a plan build manually.

A Bamboo administrator can configure global expiry for both build and deployment artifacts as described below.

Configure global expiry

Ensure that you back up any build results data before their expiry date is reached.

To enable and configure global expiry:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Expiry (under 'Plans') in the left-hand navigation panel.
3. If necessary, enable deployment expiry. Note that this can not be reversed – see the Bamboo 5.7 upgrade notes.
4. Click Edit.
5. Configure global expiry using the following settings:

   **Complete build & deployment results...**
   All build results data (including artifacts and build logs), and deployment results and release artifacts, are deleted.

   **Build and deployment result logs**
   Only user-defined artifacts are deleted.

   **Build and deployment result logs**
   Only build logs and deployment result logs are deleted. Note that log files smaller than 10MB are never expired.

   **Expire after**
   Specifies the age (days, weeks or months) that build and deployment results must reach before they are deleted. For example, specify ‘24 months’ to keep results created in the last two years.

   **Minimum builds to keep**
   Specifies the minimum number of results you want to keep. For example, specify ‘50’ to keep the latest 50 build results, even if they are older than the age specified with Expire after.

   **Keep builds with the following labels**
   Specifies the build labels (not plan labels or job labels) applied to builds for which you want to keep build results, regardless of the Expire after and Minimum builds to keep settings. Note that builds can be labeled either manually or automatically.

   **Minimum deployments to keep**
   Specifies the minimum number of successful deployments to keep, even if they are older than the age specified with Expire after. The minimum value is 2.

6. Click the icon to the right of ‘Schedule’ to set when the expiry event will be triggered. You can specify a cron expression if required. See this FAQ for help constructing cron expressions.
7. Click Save.

The global expiry event runs periodically (as determined by the expiry Schedule), regardless of whether you disable or enable expiry for your build and deployment results. When this event occurs, your build and deployment results will be expired according to the global and plan settings you have made.

Calculating the expiry date

This section outlines how the ages of build or deployment results are calculated so as to determine when they should be expired.
Build results and all logs

The ages of build results, build logs, and deployment logs are simply calculated from their respective creation dates.

If the age of the build result or log is equal to or greater than the **Expire after** age, then it is deleted when the expiry event occurs (assuming build results or logs are configured for deletion).

Note that log files smaller than 10MB are never expired.

Build and deployment artifacts

The ages of build and deployment artifacts are calculated as follows:

- If there is no release associated with the build result, then use the build result creation date.
- Otherwise, if the build result has never been deployed, then use the creation date for the latest release that refers to it.
- Otherwise, use the creation date for the latest deployment.

If the age of the build or deployment artifact is equal to or greater than the **Expire after** age, then it is deleted when the expiry event occurs (assuming artifacts are configured for deletion).

### Configuring global expiry v5.14

Global expiry allows you to manage the timing for when build and deployment artifacts should be deleted from your Bamboo system.

You may want to consider doing this for the following reasons:

- Build and deployment artifacts can be large, and so consume storage on your system. Your system may run out of disk space if artifacts no longer in active use are retained indefinitely.
- Large numbers of builds and deployments clutter the Bamboo user interface, and may reduce performance, making it slower to work with Bamboo.

See this [Atlassian blog post](https://confluence.atlassian.com/display/BAMBOO/Using+Build+Expiry+and+Labels) for a discussion of using build expiry and labels.

Global expiry applies to all build plans and deployment projects, and is generally the easiest way to manage artifacts expiry in Bamboo.

However, note that:

- You can configure **build expiry for individual build plans** to override the global expiry settings. You can **not** yet override the global expiry configuration for particular deployment projects.
- You can also **delete the results of a plan build manually**.

A Bamboo administrator can configure global expiry for both build and deployment artifacts as described below.

### Configure global expiry

Ensure that you back up any build results data before their expiry date is reached.

To enable and configure global expiry:

1. Click the ![icon](image) in the Bamboo header and choose **Overview**.
2. Click **Expire** (under 'Plans') in the left-hand navigation panel.
3. If necessary, enable deployment expiry. **Note that this can not be reversed – see the Bamboo 5.7 upgrade notes.**
4. Click **Edit**.
5. Configure global expiry using the following settings:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Complete build &amp; deployment results...</strong></td>
<td>All build results data (including artifacts and build logs), and deployment results and release artifacts, are deleted.</td>
</tr>
<tr>
<td><strong>Build and release artifacts</strong></td>
<td>Only <strong>user-defined artifacts</strong> are deleted.</td>
</tr>
<tr>
<td><strong>Build and deployment result logs</strong></td>
<td>Only <strong>build logs</strong> and deployment result logs are deleted. Note that logs can be <strong>excluded from expiry</strong> based on size.</td>
</tr>
<tr>
<td><strong>Expire after</strong></td>
<td>Specifies the age (days, weeks or months) that build and deployment results must reach before they are deleted. For example, specify '24 months' to keep results created in the last two years.</td>
</tr>
<tr>
<td><strong>Minimum builds to keep</strong></td>
<td>Specifies the minimum number of results you want to keep. For example, specify '50' to keep the latest 50 build results, even if they are older than the age specified with <strong>Expire after</strong>.</td>
</tr>
</tbody>
</table>
Keep builds with the following labels | Specifies the build labels (not plan labels or job labels) applied to builds for which you want to keep build results, regardless of the Expire after and Minimum builds to keep settings. Note that builds can be labeled either manually or automatically.

Minimum deployments to keep | Specifies the minimum number of successful deployments to keep, even if they are older than the age specified with Expire after. The minimum value is 2.

6. Click the icon to the right of ‘Schedule’ to set when the expiry event will be triggered. You can specify a cron expression if required. See this FAQ for help constructing cron expressions.

7. Click Save.

The global expiry event runs periodically (as determined by the expiry Schedule), regardless of whether you disable or enable expiry for your build and deployment results. When this event occurs, your build and deployment results will be expired according to the global and plan settings you have made.

Calculating the expiry date

This section outlines how the ages of build or deployment results are calculated so as to determine when they should be expired.

Build results and all logs

The ages of build results, build logs, and deployment logs are simply calculated from their respective creation dates.

If the age of the build result or log is equal to or greater than the Expire after age, then it is deleted when the expiry event occurs (assuming build results or logs are configured for deletion).

Note that log files smaller than 10MB are never expired.

Build and deployment artifacts

The ages of build and deployment artifacts are calculated as follows:

- If there is no release associated with the build result, then use the build result creation date.
- Otherwise, if the build result has never been deployed, then use the creation date for the latest release that refers to it.
- Otherwise, use the creation date for the latest deployment.

If the age of the build or deployment artifact is equal to or greater than the Expire after age, then it is deleted when the expiry event occurs (assuming artifacts are configured for deletion).

Configuring global expiry v6.1

Global expiry allows you to manage the timing for when build and deployment artifacts should be deleted from your Bamboo system.

You may want to consider doing this for the following reasons:

- Build and deployment artifacts can be large, and so consume storage on your system. Your system may run out of disk space if artifacts no longer in active use are retained indefinitely.
- Large numbers of builds and deployments clutter the Bamboo user interface, and may reduce performance, making it slower to work with Bamboo.

See this Atlassian blog post for a discussion of using build expiry and labels.

Global expiry applies to all build plans and deployment projects, and is generally the easiest way to manage artifacts expiry in Bamboo.

However, note that:

- You can configure build expiry for individual build plans to override the global expiry settings. You can not yet override the global expiry configuration for particular deployment projects.
- You can also delete the results of a plan build manually.

A Bamboo administrator can configure global expiry for both build and deployment artifacts as described below.

Configure global expiry

Ensure that you back up any build results data before their expiry date is reached.

To enable and configure global expiry:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Expire (under ‘Plans’) in the left-hand navigation panel.
3. If necessary, enable deployment expiry. Note that this can not be reversed – see the Bamboo 5.7 upgrade notes.
4. Click Edit.
5. Configure global expiry using the following settings:

Complete build & deployment results...
All build results data (including artifacts and build logs), and deployment results and release artifacts, are deleted.

**Build and release artifacts**
Only user-defined artifacts are deleted.

**Build and deployment result logs**
Only build logs and deployment result logs are deleted. Note that logs can be excluded from expiry based on size.

**Expire after**
Specifies the age (days, weeks or months) that build and deployment results must reach before they are deleted. For example, specify '24 months' to keep results created in the last two years.

**Minimum builds to keep**
Specifies the minimum number of results you want to keep. For example, specify '50' to keep the latest 50 build results, even if they are older than the age specified with Expire after.

**Keep builds with the following labels**
Specifies the build labels (not plan labels or job labels) applied to builds for which you want to keep build results, regardless of the Expire after and Minimum builds to keep settings. Note that builds can be labeled either manually or automatically.

**Minimum deployments to keep**
Specifies the minimum number of successful deployments to keep, even if they are older than the age specified with Expire after. The minimum value is 2.

6. Click the icon to the right of 'Schedule' to set when the expiry event will be triggered. You can specify a cron expression if required. See this FAQ for help constructing cron expressions.

7. Click Save.

The global expiry event runs periodically (as determined by the expiry Schedule), regardless of whether you disable or enable expiry for your build and deployment results. When this event occurs, your build and deployment results will be expired according to the global and plan settings you have made.

**Calculating the expiry date**

This section outlines how the ages of build or deployment results are calculated so as to determine when they should be expired.

**Build results and all logs**
The ages of build results, build logs, and deployment logs are simply calculated from their respective creation dates.

If the age of the build result or log is equal to or greater than the Expire after age, then it is deleted when the expiry event occurs (assuming build results or logs are configured for deletion).

Note that log files smaller than 10MB are never expired.

**Build and deployment artifacts**
The ages of build and deployment artifacts are calculated as follows:

- If there is no release associated with the build result, then use the build result creation date.
- Otherwise, if the build result has never been deployed, then use the creation date for the latest release that refers to it.
- Otherwise, use the creation date for the latest deployment.

If the age of the build or deployment artifact is equal to or greater than the Expire after age, then it is deleted when the expiry event occurs (assuming artifacts are configured for deletion).

**Configuring global expiry v6.4**

Global expiry allows you to manage the timing for when build and deployment artifacts should be deleted from your Bamboo system.

You may want to consider doing this for the following reasons:

- Build and deployment artifacts can be large, and so consume storage on your system. Your system may run out of disk space if artifacts no longer in active use are retained indefinitely.
- Large numbers of builds and deployments clutter the Bamboo user interface, and may reduce performance, making it slower to work with Bamboo.

See this Atlassian blog post for a discussion of using build expiry and labels.

Global expiry applies to all build plans and deployment projects, and is generally the easiest way to manage artifacts expiry in Bamboo.

However, note that:

- You can configure build expiry for individual build plans to override the global expiry settings. You can not yet override the global expiry configuration for particular deployment projects.
- You can also delete the results of a plan build manually.

A Bamboo administrator can configure global expiry for both build and deployment artifacts as described below.
Ensure that you back up any build results data before their expiry date is reached.

To enable and configure global expiry:

1. Click the icon in the Bamboo header and choose Overview.
2. Click Expiry (under ‘Plans’) in the left-hand navigation panel.
3. If necessary, enable deployment expiry. Note that this can not be reversed – see the Bamboo 5.7 upgrade notes.
4. Click Edit.
5. Configure global expiry using the following settings:

   **Complete build & deployment results...**
   All build results data (including artifacts and build logs), and deployment results and release artifacts, are deleted.

   **Build and release artifacts**
   Only user-defined artifacts are deleted.

   **Build and deployment result logs**
   Only build logs and deployment result logs are deleted. Note that log files smaller than 10MB are never expired.

   **Expire after**
   Specifies the age (days, weeks or months) that build and deployment results must reach before they are deleted.
   For example, specify '24 months' to keep results created in the last two years.

   **Minimum builds to keep**
   Specifies the minimum number of results you want to keep.
   For example, specify '50' to keep the latest 50 build results, even if they are older than the age specified with Expire after.

   **Keep builds with the following labels**
   Specifies the (not plan labels or job labels) applied to builds for which you want to keep build results, regardless of the Expire after and Minimum builds to keep settings. Note that builds can be labeled either manually or automatically.

   **Minimum deployments to keep**
   Specifies the minimum number of successful deployments to keep, even if they are older than the age specified with Expire after.
   The minimum value is 2.

6. Click the icon to the right of ‘Schedule’ to set when the expiry event will be triggered. You can specify a cron expression if required.

   See this FAQ for help constructing cron expressions.

7. Click Save.

The global expiry event runs periodically (as determined by the expiry Schedule), regardless of whether you disable or enable expiry for your build and deployment results. When this event occurs, your build and deployment results will be expired according to the global and plan settings you have made.

**Calculating the expiry date**

This section outlines how the ages of build or deployment results are calculated so as to determine when they should be expired.

**Build results and all logs**

The ages of build results, build logs, and deployment logs are simply calculated from their respective creation dates.

If the age of the build result or log is equal to or greater than the Expire after age, then it is deleted when the expiry event occurs (assuming build results or logs are configured for deletion).

Note that log files smaller than 10MB are never expired.

**Build and deployment artifacts**

The ages of build and deployment artifacts are calculated as follows:

- If there is no release associated with the build result, then use the build result creation date.
- Otherwise, if the build result has never been deployed, then use the creation date for the latest release that refers to it.
- Otherwise, use the creation date for the latest deployment.

If the age of the build or deployment artifact is equal to or greater than the Expire after age, then it is deleted when the expiry event occurs (assuming artifacts are configured for deletion).

.Configuring global expiry v6.5

Global expiry allows you to manage the timing for when build and deployment artifacts should be deleted from your Bamboo system.

You may want to consider doing this for the following reasons:

- Build and deployment artifacts can be large, and so consume storage on your system. Your system may run out of disk space if artifacts no longer in active use are retained indefinitely.
- Large numbers of builds and deployments clutter the Bamboo user interface, and may reduce performance, making it slower to work
with Bamboo.

See this [Atlassian blog post](https://confluence.atlassian.com/x/UH5pB) for a discussion of using build expiry and labels.

Global expiry applies to all build plans and deployment projects, and is generally the easiest way to manage artifacts expiry in Bamboo. However, note that:

- You can configure build expiry for individual build plans to override the global expiry settings. You can *not* yet override the global expiry configuration for particular deployment projects.
- You can also delete the results of a plan build manually.

A Bamboo administrator can configure global expiry for both build and deployment artifacts as described below.

### Configure global expiry

Ensure that you back up any build results data before their expiry date is reached.

To enable and configure global expiry:

1. Click the **icon** in the Bamboo header and choose **Overview**.
2. Click **Expire** (under "Plans") in the left-hand navigation panel.
3. If necessary, enable deployment expiry. *Note that this can not be reversed – see the Bamboo 5.7 upgrade notes.*
4. Click **Edit**.
5. Configure global expiry using the following settings:

   **Complete build & deployment results...**
   All build results data (including artifacts and build logs), and deployment results and release artifacts, are deleted.

   **Build and release artifacts**
   Only user-defined artifacts are deleted.

   **Build and deployment result logs**
   Only build logs and deployment result logs are deleted. Note that logs can be excluded from expiry based on size.

   **Expire after**
   Specifies the age (days, weeks or months) that build and deployment results must reach before they are deleted. For example, specify '24 months' to keep results created in the last two years.

   **Minimum builds to keep**
   Specifies the minimum number of builds you want to keep. For example, specify '50' to keep the latest 50 build results, even if they are older than the age specified with **Expire after**.

   **Keep builds with the following labels**
   Specifies the build labels (not plan labels or job labels) applied to builds for which you want to keep build results, regardless of the **Expire after** and **Minimum builds to keep** settings. Note that builds can be labeled either manually or automatically.

   **Minimum deployments to keep**
   Specifies the minimum number of successful deployments to keep, even if they are older than the age specified with **Expire after**. The minimum value is 2.

6. Click the icon to the right of 'Schedule' to set when the expiry event will be triggered. You can specify a cron expression if required.
7. See this FAQ for help constructing cron expressions.
8. Click **Save**.

The global expiry event runs periodically (as determined by the expiry **Schedule**), regardless of whether you disable or enable expiry for your build and deployment results. When this event occurs, your build and deployment results will be expired according to the global and plan settings you have made.

### Calculating the expiry date

This section outlines how the ages of build or deployment results are calculated so as to determine when they should be expired.

**Build results and all logs**

The ages of build results, build logs, and deployment logs are simply calculated from their respective creation dates.

If the age of the build result or log is equal to or greater than the **Expire after** age, then it is deleted when the expiry event occurs (assuming build results or logs are configured for deletion).

Note that logs can be excluded from expiry based on size.

**Build and deployment artifacts**

The ages of build and deployment artifacts are calculated as follows:
If there is no release associated with the build result, then use the build result creation date. Otherwise, if the build result has never been deployed, then use the creation date for the latest release that refers to it. Otherwise, use the creation date for the latest deployment.

If the age of the build or deployment artifact is equal to or greater than the **Expire after** age, then it is deleted when the expiry event occurs (assuming artifacts are configured for deletion).

### Importing data from Jenkins

The Jenkins Importer helps you to migrate projects deployed in Jenkins to Bamboo.

On this page:

- Requirements & supported configurations
- Using the Jenkins importer
- Getting Help

Related pages:

- Getting started with Java and Bamboo
- Getting started with .NET and Bamboo
- Using Bamboo
- Installing and upgrading

#### Requirements & supported configurations

While the importer assists and supports the migration of projects from Jenkins to Bamboo, a small amount of manual configuration may also be required.

<table>
<thead>
<tr>
<th>Jenkins Version</th>
<th>Required Dependencies*</th>
<th>Jenkins Project Types</th>
<th>Repository Types</th>
<th>Build Steps</th>
<th>Notifications</th>
<th>Parameter Types</th>
<th>Other plugins</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jenkins 1.581</td>
<td>Jenkins built-in job dependencies</td>
<td>Freestyle</td>
<td>Git 1.1.25</td>
<td>Maven</td>
<td>Email</td>
<td>Boolean</td>
<td>EnvInject plugin 1.73</td>
</tr>
<tr>
<td>Jenkins 1.581</td>
<td>Pipelines plugin 1.3.3</td>
<td>Freestyle</td>
<td>SVN 1.43</td>
<td>Ant 1.1</td>
<td>Choice</td>
<td>JavaDoc 1.0</td>
<td></td>
</tr>
<tr>
<td>Jenkins 1.581</td>
<td>Join plugin 1.15</td>
<td>Freestyle</td>

<td>Password</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Required Dependencies are the functional Jenkins plugins that the Bamboo Jenkins Importer requires to be present. These must be present in your Jenkins instance.

#### Using the Jenkins importer

1. **Start the importer**

You must have administration privileges to run the Jenkins Importer.

The Jenkins Importer is accessed from the welcome screen or Administration panel. To start the Jenkins Importer:

**If running Bamboo for the first time**

From the Bamboo Welcome screen:

1. Click **Import from...**
2. Select **Import from Jenkins**.

**If already running Bamboo**

From anywhere within the Bamboo interface:

1. Click on the **Administration** tab at the top of the Bamboo interface
2. Scroll down to the **System** side panel
3. Click on **Import from Jenkins**.
The Locate Jenkins screen will appear.

2. **Select Jenkins data for importing**

You may either import Jenkins data from its home location on the Bamboo server, or you may import from a zipped archive of your Jenkins home:

<table>
<thead>
<tr>
<th>Importing from the Jenkins home location</th>
</tr>
</thead>
<tbody>
<tr>
<td>From the Locate Jenkins interface:</td>
</tr>
<tr>
<td>1. Click the <strong>Source of Jenkins home</strong> dropdown menu</td>
</tr>
<tr>
<td>2. Select <strong>Location on the Bamboo server</strong></td>
</tr>
<tr>
<td>3. Enter the path to your Jenkins home directory in the text field</td>
</tr>
<tr>
<td>4. Click <strong>Next</strong>.</td>
</tr>
</tbody>
</table>

You must specify the path to your Jenkins **home** directory.

<table>
<thead>
<tr>
<th>Importing from an archived Jenkins home</th>
</tr>
</thead>
<tbody>
<tr>
<td>From anywhere within the Bamboo interface:</td>
</tr>
<tr>
<td>1. Click the <strong>Source of Jenkins home</strong> dropdown menu</td>
</tr>
<tr>
<td>2. Select <strong>Upload a zip archive</strong></td>
</tr>
<tr>
<td>3. Click <strong>Choose Files</strong>. A file manager window will open. Use it to locate your zipped Jenkins home directory</td>
</tr>
<tr>
<td>4. Click <strong>Next</strong>.</td>
</tr>
</tbody>
</table>

When creating your Jenkins zip archive, you need to remove or exclude the **userContent** and **builds** directory for each job from the archive before zipping:

1. Make a copy of Jenkins home 
2. Remove/exclude the userContent directory 
3. Remove/exclude the builds directory 
4. Zip the archive.

Bamboo Jenkins Importer supports only ZIP file archives. Other archive formats such as tar and tar.gz are not currently supported.

Once you have selected your Jenkins data and clicked **Next**, the Jenkins job and pipeline selector will open.

3. **Configure Jenkins data for import**

The Job and Pipeline selector screen allows you to select and configure which Jenkins import items you would like to import into Bamboo. Import items include Jenkins pipelines and jobs, and the importer will identify how many items were found for processing:
The Jenkins Importer processes both Jenkins pipelines and jobs, but handles each differently:

<table>
<thead>
<tr>
<th>Jenkins Import Item</th>
<th>Description</th>
<th>Bamboo Equivalent</th>
<th>Jenkins Importer Process</th>
</tr>
</thead>
</table>
| Pipeline            | A group of associated jobs linked using a Jenkins pipeline | Plan              | • Creates a new Bamboo plan  
|                     |                                                  |                   | • Imports individual pipeline jobs as Bamboo jobs into the new plan |
| Job                 | A stand alone build job                          | Job               | • Imports job into a Bamboo plan with a single associated job within the plan |

**Importing a Jenkins job**

To import a Jenkins job:

1. Locate the relevant Jenkins Import item on the selector screen
2. Ensure the **Import Jobs** check box is checked
3. Enter a **Bamboo Job Name** (or leave to accept the default name from Jenkins)
4. Check the **Enabled in Bamboo?** check box. To disable an imported job, leave the box unchecked. Bamboo will not automatically run a disabled job.

By default, all jobs are selected for importing. To reject a Jenkins job for importation:

1. Locate the relevant Jenkins Import item on the selector screen
2. Uncheck the **Import Jobs** check box

**Importing a Jenkins pipeline**

To import a Jenkins pipeline, all of the associated jobs must be imported. The importing of individual jobs is described above.

**Changing the imported Bamboo plan or job name**

By default, the Jenkins Importer uses the Jenkins import item name as the default for the Bamboo name. To change the default name:

1. Locate the relevant Jenkins Import item on the selector screen
2. Enter a new name in the **Bamboo Plan Name** text field

**Existing Bamboo plans**

Existing Bamboo plans are not overwritten when you use the Jenkins Importer. When importing Jenkins data, Bamboo creates a new project called 'Imported from Jenkins' to contain all of the newly imported plans.

**Starting the import**

When you have identified and selected all of the Jenkins import items that you require, click **Next** at the bottom of the screen. Bamboo will start to import the specified plans and a progress indicator screen will display:
Once importing has finished, the importer results screen will display.

4. Review the importer results

The Importer Results screen shows the success outcome of the import activity for each import item. The three possible success outcomes are:

- Success
- Partial
- Fail

An example of Importer results is seen below.

Success

A 'success' result indicates that the Jenkins item was successfully imported into Bamboo. No additional work is required.

Partial

A 'partial' result indicates that the import was partially successful, however there may be unmapped configuration or other issues that require attention.

Fail

A 'fail' result indicates that the importer was unable to import the Jenkins job or pipeline if the repository type is unsupported, none of the build steps could be converted to tasks or another unknown error occurred.

The Import log

In the case of a fail or partial, additional information can be obtained from the Import log, which provides the following:

- The name of the attempted job import
- The severity if the problem/issue. Severity is rated as:
  - Low – warning that might be interesting to the administrator such as how dependencies were imported
  - Medium – unsupported publishers or other configurations that are non-critical to running the build
  - High – unsupported repository or none of the build steps could be imported
  - Fatal – un-handled error that prevents the job from importing at all
- A brief description of the problem/issue.

An example Import Log entry can be seen below:

```
-------------------------------------
Job name: SPLAN_DOCS
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase UCM Plugin'
```

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
It is possible that an import item has multiple problems/issues. Where this is the case, the Import Log will identify the severity and brief description for each problem/issue associated with an import item. An example Import Log entry detailing multiple problems/issues can be seen below:

```
Job name: DLINK_CODE_CHECK
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase Plugin'
SEVERITY: HIGH
Requested plugin parameterized-trigger but we don't support it
SEVERITY: HIGH
Requested plugin downstream-ext but we don't support it
SEVERITY: FATAL
Scm cannot be imported
```

The import log is accessed by clicking on the Import Log link associated with an import issue, or by clicking on the Download import log file button at the base of the Import Results screen.

Missing or incompatible plugins

From time to time, Bamboo may not support particular Jenkins functionality. When this occurs, a great place to look is the Atlassian Marketplace. The Marketplace contains over 120 add-ons and plugins for Bamboo, and you will more than likely find a plugin for your functionality there. If you can't find what you need in the Marketplace, then consult the ‘Getting help’ section below.

5. View the imported plans

Once you have completed examining the importer results, click on View Plans to examine the imported plans in the Bamboo dashboard. An example of plans imported from Jenkins is seen below:

Imported plans can now be configured and managed using existing Bamboo methods.

Getting Help

Support

Help with the Jenkins importer is never far away. The best way to get help is to raise a support ticket directly via the Atlassian support site.

To create a support ticket:
1. Download the import log
2. Go to https://support.atlassian.com and select Create New Issue
3. Enter a detailed description of your problem within the support ticket
4. Attach the import log and lodge your support ticket
5. Wait to be notified of updates by Email

Importing data from Jenkins v5.14

The Jenkins Importer helps you to migrate projects deployed in Jenkins to Bamboo. On this page:

The Required Dependencies are the functional Jenkins plugins that the Bamboo Jenkins Importer requires to be present. These must be present in your Jenkins instance.

Using the Jenkins importer

1. Start the importer

You must have administration privileges to run the Jenkins Importer

The Jenkins Importer is accessed from the welcome screen or Administration panel. To start the Jenkins Importer:

If running Bamboo for the first time

From the Bamboo Welcome screen:

1. Click Import from...
2. Select Import from Jenkins.
If already running Bamboo

From anywhere within the Bamboo interface:

1. Click on the Administration tab at the top of the Bamboo interface
2. Scroll down to the System side panel
3. Click on Import from Jenkins.

The Locate Jenkins screen will appear.

2. Select Jenkins data for importing

You may either import Jenkins data from its home location on the Bamboo server, or you may import from a zipped archive of your Jenkins home:

Importing from the Jenkins home location

From the Locate Jenkins interface:

1. Click the Source of Jenkins home dropdown menu
2. Select Location on the Bamboo server
3. Enter the path to your Jenkins home directory in the text field
4. Click Next.

You must specify the path to your Jenkins home directory.

Importing from an archived Jenkins home

From anywhere within the Bamboo interface:

1. Click the Source of Jenkins home dropdown menu
2. Select Upload a zip archive
3. Click Choose Files. A file manager window will open. Use it to locate your zipped Jenkins home directory
4. Click Next.

When creating your Jenkins zip archive, you need to remove or exclude the userContent and builds directory for each job from the archive before zipping:

1. Make a copy of Jenkins home
2. Remove/exclude the userContent directory
3. Remove/exclude the builds directory
4. Zip the archive.

Bamboo Jenkins Importer supports only ZIP file archives. Other archive formats such as tar and tar.gz are not currently supported.

Once you have selected your Jenkins data and clicked Next, the Jenkins job and pipeline selector will open.

3. Configure Jenkins data for import

The Job and Pipeline selector screen allows you to select and configure which Jenkins import items you would like to import into Bamboo. Import items include Jenkins pipelines and jobs, and the importer will identify how many items were found for processing.
The Jenkins Importer processes both Jenkins pipelines and jobs, but handles each differently:

<table>
<thead>
<tr>
<th>Jenkins Import Item</th>
<th>Description</th>
<th>Bamboo Equivalent</th>
<th>Jenkins Importer Process</th>
</tr>
</thead>
</table>
| Pipeline            | A group of associated jobs linked using a Jenkins pipeline | Plan | • Creates a new Bamboo plan  
• Imports individual pipeline jobs as Bamboo jobs into the new plan |
| Job                 | A stand alone build job | Job | • Imports job into a Bamboo plan with a single associated job within the plan |

**Importing a Jenkins job**

To import a Jenkins job:

1. Locate the relevant Jenkins Import item on the selector screen
2. Ensure the Import Jobs check box is checked
3. Enter a Bamboo Job Name (or leave to accept the default name from Jenkins)
4. Check the Enabled in Bamboo? check box. To disable an imported job, leave the box unchecked. Bamboo will not automatically run a disabled job.

By default, all jobs are selected for importing. To reject a Jenkins job for importation:

1. Locate the relevant Jenkins Import item on the selector screen
2. Uncheck the Import Jobs check box

**Importing a Jenkins pipeline**

To import a Jenkins pipeline, all of the associated jobs must be imported. The importing of individual jobs is described above.

**Changing the imported Bamboo plan or job name**

By default, the Jenkins Importer uses the Jenkins import item name as the default for the Bamboo name. To change the default name:

1. Locate the relevant Jenkins Import item on the selector screen
2. Enter a new name in the Bamboo Plan Name text field

**Existing Bamboo plans**

Existing Bamboo plans are not overwritten when you use the Jenkins Importer. When importing Jenkins data, Bamboo creates a new project called 'Imported from Jenkins' to contain all of the newly imported plans.

**Starting the import**

When you have identified and selected all of the Jenkins import items that you require, click Next at the bottom of the screen. Bamboo will start to import the specified plans and a progress indicator screen will display:
Once importing has finished, the importer results screen will display.

4. Review the importer results

The Importer Results screen shows the success outcome of the import activity for each import item. The three possible success outcomes are:

- **Success**
- **Partial**
- **Fail**

An example of Importer results is seen below.

<table>
<thead>
<tr>
<th>Jenkins Job Name</th>
<th>Success/Partial/Fail</th>
<th>Import Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPLAN_DOCS</td>
<td>PARTIAL</td>
<td>Partial</td>
</tr>
<tr>
<td>DLINK_CODE_CHECK</td>
<td>FAIL</td>
<td>Fail</td>
</tr>
<tr>
<td>SPLAN_DEPLOY</td>
<td>SUCCESS</td>
<td>Success</td>
</tr>
</tbody>
</table>

**Success**

A 'success' result indicates that the Jenkins item was successfully imported into Bamboo. No additional work is required.

**Partial**

A 'partial' result indicates that the import was partially successful, however there may be unmapped configuration or other issues that require attention.

**Fail**

A 'fail' result indicates that the importer was unable to import the Jenkins job or pipeline if the repository type is unsupported, none of the build steps could be converted to tasks or another unknown error occurred.

**The Import log**

In the case of a fail or partial, additional information can be obtained from the Import log, which provides the following:

- The name of the attempted job import
- The severity if the problem/issue. Severity is rated as:
  - Low – warning that might be interesting to the administrator such as how dependencies were imported
  - Medium – unsupported publishers or other configurations that are non-critical to running the build
  - High – unsupported repository or none of the build steps could be imported
  - Fatal – un-handled error that prevents the job from importing at all
- A brief description of the problem/issue.

An example Import Log entry can be seen below:

```
-----------------------------
Job name: SPLAN_DOCS
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase UCM Plugin'
-----------------------------
```
It is possible that an import item has multiple problems/issues. Where this is the case, the Import Log will identify the severity and brief description for each problem/issue associated with an import item. An example Import Log entry detailing multiple problems/issues can be seen below:

```
Job name: DLINK_CODE_CHECK
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase Plugin'
SEVERITY: HIGH
Requested plugin parameterized-trigger but we don't support it
SEVERITY: HIGH
Requested plugin downstream-ext but we don't support it
SEVERITY: FATAL
Scm cannot be imported
```

The import log is accessed by clicking on the Import Log link associated with an import issue, or by clicking on the **Download import log file** button at the base of the Import Results screen.

**Missing or incompatible plugins**

From time to time, Bamboo may not support particular Jenkins functionality. When this occurs, a great place to look is the Atlassian Marketplace. The Marketplace contains over 120 add-ons and plugins for Bamboo, and you will more than likely find a plugin for your functionality there. If you can't find what you need in the Marketplace, then consult the 'Getting help' section below.

5. View the imported plans

Once you have completed examining the importer results, click on **View Plans** to examine the imported plans in the Bamboo dashboard. An example of plans imported from Jenkins is seen below:

```
<table>
<thead>
<tr>
<th>Plan</th>
<th>Build</th>
<th>Completed</th>
<th>Tests</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSP_DEMO_SNAPSHOT_SONAR_BUILD</td>
<td>Never Built</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BSP_PARC_ALL_DASHBOARD_BUILD</td>
<td>#28</td>
<td>13 minutes ago</td>
<td>No tests found</td>
<td>Scheduled</td>
</tr>
<tr>
<td>BSP_PARC_ARTIFACTORY_DASHBOARD_BUILD</td>
<td>Never Built</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BSP_PARC_NIGHTLY_DASHBOARD_BUILD</td>
<td>#2</td>
<td>11 hours ago</td>
<td>No tests found</td>
<td>Scheduled</td>
</tr>
<tr>
<td>BSP_PARC_RELEASE_BUILD_CLEARCASE_DASHBOARD_BUILD</td>
<td>Never Built</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BSP_PARC_RELEASE_BUILD_GIT_DASHBOARD_BUILD</td>
<td>Never Built</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Build Pipeline Dashboard View</td>
<td>#1</td>
<td>1 day ago</td>
<td>No tests found</td>
<td>First build for this plan</td>
</tr>
<tr>
<td>PARC_RELEASE_BUILD_GIT</td>
<td>Never Built</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SCM_CONFIG_SAVE</td>
<td>Never Built</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Imported plans can now be configured and managed using existing Bamboo methods.

**Getting Help**

**Support**

Help with the Jenkins importer is never far away. The best way to get help is to raise a support ticket directly via the Atlassian support site.

To create a support ticket:

1. Download the import log
2. Go to https://support.atlassian.com and select Create New Issue
3. Enter a detailed description of your problem within the support ticket
4. Attach the import log and lodge your support ticket
5. Wait to be notified of updates by Email

The Required Dependencies are the functional Jenkins plugins that the Bamboo Jenkins Importer requires to be present. These must be present in your Jenkins instance.

Using the Jenkins importer

1. Start the importer

You must have administration privileges to run the Jenkins Importer

The Jenkins Importer is accessed from the welcome screen or Administration panel. To start the Jenkins Importer:

If running Bamboo for the first time

From the Bamboo Welcome screen:
1. Click Import from...
2. Select Import from Jenkins.
If already running Bamboo

From anywhere within the Bamboo interface:
1. Click on the Administration tab at the top of the Bamboo interface
2. Scroll down to the System side panel
3. Click on Import from Jenkins.

The Locate Jenkins screen will appear.

2. Select Jenkins data for importing

You may either import Jenkins data from its home location on the Bamboo server, or you may import from a zipped archive of your Jenkins home:

**Importing from the Jenkins home location**

From the Locate Jenkins interface:
1. Click the Source of Jenkins home dropdown menu
2. Select Location on the Bamboo server
3. Enter the path to your Jenkins home directory in the text field
4. Click Next.

You must specify the path to your Jenkins home directory.

**Importing from an archived Jenkins home**

From anywhere within the Bamboo interface:
1. Click the Source of Jenkins home dropdown menu
2. Select Upload a zip archive
3. Click Choose Files. A file manager window will open. Use it to locate your zipped Jenkins home directory
4. Click Next.

When creating your Jenkins zip archive, you need to remove or exclude the userContent and builds directory for each job from the archive before zipping:
1. Make a copy of Jenkins home
2. Remove/exclude the userContent directory
3. Remove/exclude the builds directory
4. Zip the archive.

Bamboo Jenkins Importer supports only ZIP file archives. Other archive formats such as tar and tar.gz are not currently supported.

Once you have selected your Jenkins data and clicked Next, the Jenkins job and pipeline selector will open.

3. Configure Jenkins data for import

The Job and Pipeline selector screen allows you to select and configure which Jenkins import items you would like to import into Bamboo. Import items include Jenkins pipelines and jobs, and the importer will identify how many items were found for processing:
The Jenkins Importer processes both Jenkins pipelines and jobs, but handles each differently:

<table>
<thead>
<tr>
<th>Jenkins Import Item</th>
<th>Description</th>
<th>Bamboo Equivalent</th>
<th>Jenkins Importer Process</th>
</tr>
</thead>
</table>
| Pipeline            | A group of associated jobs linked using a Jenkins pipeline | Plan              | • Creates a new Bamboo plan  
• Imports individual pipeline jobs as Bamboo jobs into the new plan                    |
| Job                 | A stand alone build job                          | Job               | • Imports job into a Bamboo plan with a single associated job within the plan            |

**Importing a Jenkins job**

To import a Jenkins job:

1. Locate the relevant Jenkins Import item on the selector screen
2. Ensure the **Import Jobs** check box is checked
3. Enter a **Bamboo Job Name** (or leave to accept the default name from Jenkins)
4. Check the **Enabled in Bamboo?** check box. To disable an imported job, leave the box unchecked. Bamboo will not automatically run a disabled job.

By default, all jobs are selected for importing. To reject a Jenkins job for importation:

1. Locate the relevant Jenkins Import item on the selector screen
2. Uncheck the **Import Jobs** check box

**Importing a Jenkins pipeline**

To import a Jenkins pipeline, all of the associated jobs must be imported. The importing of individual jobs is described above.

**Changing the imported Bamboo plan or job name**

By default, the Jenkins Importer uses the Jenkins import item name as the default for the Bamboo name. To change the default name:

1. Locate the relevant Jenkins Import item on the selector screen
2. Enter a new name in the **Bamboo Plan Name** text field

**Existing Bamboo plans**

Existing Bamboo plans are not overwritten when you use the Jenkins Importer. When importing Jenkins data, Bamboo creates a new project called 'Imported from Jenkins' to contain all of the newly imported plans.

**Starting the import**

When you have identified and selected all of the Jenkins import items that you require, click **Next** at the bottom of the screen. Bamboo will start to import the specified plans and a progress indicator screen will display:
Once importing has finished, the importer results screen will display.

4. Review the importer results

The Importer Results screen shows the success outcome of the import activity for each import item. The three possible success outcomes are:

- **Success**
- **Partial**
- **Fail**

An example of Importer results is seen below.

<table>
<thead>
<tr>
<th>Job name</th>
<th>Status</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPLAN_DOCS</td>
<td>PARTIAL</td>
<td>Imported with warnings. See Import log for details.</td>
</tr>
<tr>
<td>DLINK_CODE_CHECK</td>
<td>FAIL</td>
<td>Could not import due to fatal error. See Import log for details.</td>
</tr>
<tr>
<td>SPLAN_DEPLOY</td>
<td>SUCCESS</td>
<td></td>
</tr>
</tbody>
</table>

**Success**

A *success* result indicates that the Jenkins item was successfully imported into Bamboo. No additional work is required.

**Partial**

A *partial* result indicates that the import was partially successful, however there may be unmapped configuration or other issues that require attention.

**Fail**

A *fail* result indicates that the importer was unable to import the Jenkins job or pipeline if the repository type is unsupported, none of the build steps could be converted to tasks or another unknown error occurred.

**The Import log**

In the case of a fail or partial, additional information can be obtained from the Import log, which provides the following:

- The name of the attempted job import
- The severity if the problem/issue. Severity is rated as:
  - Low – warning that might be interesting to the administrator such as how dependencies were imported
  - Medium – unsupported publishers or other configurations that are non-critical to running the build
  - High – unsupported repository or none of the build steps could be imported
  - Fatal – un-handled error that prevents the job from importing at all
- A brief description of the problem/issue.

An example Import Log entry can be seen below:

```
-------------------------------------------------
Job name: SPLAN_DOCS
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase UCM Plugin'
-------------------------------------------------
```
It is possible that an import item has multiple problems/issues. Where this is the case, the Import Log will identify the severity and brief description for each problem/issue associated with an import item. An example Import Log entry detailing multiple problems/issues can be seen below:

```
-------------------------------------------------
Job name: DLINK_CODE_CHECK
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase Plugin'
SEVERITY: HIGH
Requested plugin parameterized-trigger but we don't support it
SEVERITY: HIGH
Requested plugin downstream-ext but we don't support it
SEVERITY: FATAL
Scm cannot be imported
-------------------------------------------------
```

The import log is accessed by clicking on the Import Log link associated with an import issue, or by clicking on the Download import log file button at the base of the Import Results screen.

**Missing or incompatible plugins**

From time to time, Bamboo may not support particular Jenkins functionality. When this occurs, a great place to look is the [Atlassian Marketplace](https://marketplace.atlassian.com). The Marketplace contains over 120 add-ons and plugins for Bamboo, and you will more than likely find a plugin for your functionality there. If you can't find what you need in the Marketplace, then consult the 'Getting help' section below.

5. View the imported plans

Once you have completed examining the importer results, click on View Plans to examine the imported plans in the Bamboo dashboard. An example of plans imported from Jenkins is seen below:

The Required Dependencies are the functional Jenkins plugins that the Bamboo Jenkins Importer requires to be present. These must be present in your Jenkins instance.

Using the Jenkins importer

1. Start the importer

   You must have administration privileges to run the Jenkins Importer

The Jenkins Importer is accessed from the welcome screen or Administration panel. To start the Jenkins Importer:

   If running Bamboo for the first time
   From the Bamboo Welcome screen:
   1. Click Import from...
   2. Select Import from Jenkins.
If already running Bamboo

From anywhere within the Bamboo interface:

1. Click on the Administration tab at the top of the Bamboo interface
2. Scroll down to the System side panel
3. Click on Import from Jenkins.

The Locate Jenkins screen will appear.

2. Select Jenkins data for importing

You may either import Jenkins data from its home location on the Bamboo server, or you may import from a zipped archive of your Jenkins home:

Importing from the Jenkins home location

From the Locate Jenkins interface:

1. Click the Source of Jenkins home dropdown menu
2. Select Location on the Bamboo server
3. Enter the path to your Jenkins home directory in the text field
4. Click Next.

You must specify the path to your Jenkins home directory.

Importing from an archived Jenkins home

From anywhere within the Bamboo interface:

1. Click the Source of Jenkins home dropdown menu
2. Select Upload a zip archive
3. Click Choose Files. A file manager window will open. Use it to locate your zipped Jenkins home directory
4. Click Next.

When creating your Jenkins zip archive, you need to remove or exclude the userContent and builds directory for each job from the archive before zipping:

1. Make a copy of Jenkins home
2. Remove/exclude the userContent directory
3. Remove/exclude the builds directory
4. Zip the archive.

Bamboo Jenkins Importer supports only ZIP file archives. Other archive formats such as tar and tar.gz are not currently supported.

Once you have selected your Jenkins data and clicked Next, the Jenkins job and pipeline selector will open.

3. Configure Jenkins data for import

The Job and Pipeline selector screen allows you to select and configure which Jenkins import items you would like to import into Bamboo. Import items include Jenkins pipelines and jobs, and the importer will identify how many items were found for processing:
The Jenkins Importer processes both Jenkins pipelines and jobs, but handles each differently:

<table>
<thead>
<tr>
<th>Jenkins Import Item</th>
<th>Description</th>
<th>Bamboo Equivalent</th>
<th>Jenkins Importer Process</th>
</tr>
</thead>
</table>
| Pipeline            | A group of associated jobs linked using a Jenkins pipeline | Plan | • Creates a new Bamboo plan  
• Imports individual pipeline jobs as Bamboo jobs into the new plan |
| Job                 | A stand alone build job | Job | • Imports job into a Bamboo plan with a single associated job within the plan |

**Importing a Jenkins job**

To import a Jenkins job:

1. Locate the relevant Jenkins Import item on the selector screen
2. Ensure the Import Jobs check box is checked
3. Enter a Bamboo Job Name (or leave to accept the default name from Jenkins)
4. Check the Enabled in Bamboo? check box. To disable an imported job, leave the box unchecked. Bamboo will not automatically run a disabled job.

By default, all jobs are selected for importing. To reject a Jenkins job for importation:

1. Locate the relevant Jenkins Import item on the selector screen
2. Uncheck the Import Jobs check box

**Importing a Jenkins pipeline**

To import a Jenkins pipeline, all of the associated jobs must be imported. The importing of individual jobs is described above.

*Changing the imported Bamboo plan or job name*

By default, the Jenkins Importer uses the Jenkins import item name as the default for the Bamboo name. To change the default name:

1. Locate the relevant Jenkins Import item on the selector screen
2. Enter a new name in the Bamboo Plan Name text field

**Existing Bamboo plans**

Existing Bamboo plans are not overwritten when you use the Jenkins Importer. When importing Jenkins data, Bamboo creates a new project called ‘Imported from Jenkins’ to contain all of the newly imported plans.

**Starting the import**

When you have identified and selected all of the Jenkins import items that you require, click Next at the bottom of the screen. Bamboo will start to import the specified plans and a progress indicator screen will display:
Once importing has finished, the importer results screen will display.

4. Review the importer results

The Importer Results screen shows the success outcome of the import activity for each import item. The three possible success outcomes are:

- **Success**
- **Partial**
- **Fail**

An example of Importer results is seen below.

<table>
<thead>
<tr>
<th>Jenkins Item</th>
<th>Result</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPLAN_DOCS</td>
<td>PARTIAL</td>
<td>Imported with warnings. See Import log for details</td>
</tr>
<tr>
<td>DLINK_CODE_CHECK</td>
<td>FAIL</td>
<td>Could not import due to fatal error. See Import log for details</td>
</tr>
<tr>
<td>SPLAN_DEPLOY</td>
<td>SUCCESS</td>
<td></td>
</tr>
</tbody>
</table>

**Success**

A **success** result indicates that the Jenkins item was successfully imported into Bamboo. No additional work is required.

**Partial**

A **partial** result indicates that the import was partially successful, however there may be unmapped configuration or other issues that require attention.

**Fail**

A **fail** result indicates that the importer was unable to import the Jenkins job or pipeline if the repository type is unsupported, none of the build steps could be converted to tasks or another unknown error occurred.

**The Import log**

In the case of a fail or partial, additional information can be obtained from the Import log, which provides the following:

- The name of the attempted job import
- The severity if the problem/issue. Severity is rated as:
  - Low – warning that might be interesting to the administrator such as how dependencies were imported
  - Medium – unsupported publishers or other configurations that are non-critical to running the build
  - High – unsupported repository or none of the build steps could be imported
  - Fatal – un-handled error that prevents the job from importing at all
- A brief description of the problem/issue.

An example Import Log entry can be seen below:

```
-------------------------------------------------
Job name: SPLAN_DOCS
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase UCM Plugin'
-------------------------------------------------
```
It is possible that an import item has multiple problems/issues. Where this is the case, the Import Log will identify the severity and brief description for each problem/issue associated with an import item. An example Import Log entry detailing multiple problems/issues can be seen below:

```
Job name: DLINK_CODE_CHECK
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase Plugin'
SEVERITY: HIGH
Requested plugin parameterized-trigger but we don't support it
SEVERITY: HIGH
Requested plugin downstream-ext but we don't support it
SEVERITY: FATAL
Scm cannot be imported
```

The import log is accessed by clicking on the Import Log link associated with an import issue, or by clicking on the Download import log file button at the base of the Import Results screen.

**Missing or incompatible plugins**

From time to time, Bamboo may not support particular Jenkins functionality. When this occurs, a great place to look is the Atlassian Marketplace. The Marketplace contains over 120 add-ons and plugins for Bamboo, and you will more than likely find a plugin for your functionality there. If you can't find what you need in the Marketplace, then consult the 'Getting help' section below.

5. View the imported plans

Once you have completed examining the importer results, click on View Plans to examine the imported plans in the Bamboo dashboard. An example of plans imported from Jenkins is seen below:

![Imported plans](example.png)

Imported plans can now be configured and managed using existing Bamboo methods.

**Getting Help**

**Support**

Help with the Jenkins importer is never far away. The best way to get help is to raise a support ticket directly via the Atlassian support site.

To create a support ticket:

1. Download the import log
2. Go to https://support.atlassian.com and select Create New Issue
3. Enter a detailed description of your problem within the support ticket
4. Attach the import log and lodge your support ticket
5. Wait to be notified of updates by Email

Importing data from Jenkins v6.1

The Jenkins Importer helps you to migrate projects deployed in Jenkins to Bamboo.

</tbody>
</table>

The Required Dependencies are the functional Jenkins plugins that the Bamboo Jenkins Importer requires to be present. These must be present in your Jenkins instance.

Using the Jenkins importer

1. Start the importer

   You must have administration privileges to run the Jenkins Importer

The Jenkins Importer is accessed from the welcome screen or Administration panel. To start the Jenkins Importer:

If running Bamboo for the first time

From the Bamboo Welcome screen:
1. Click Import from...
2. Select Import from Jenkins.
If already running Bamboo

From anywhere within the Bamboo interface:
1. Click on the Administration tab at the top of the Bamboo interface
2. Scroll down to the System side panel
3. Click on Import from Jenkins.

The Locate Jenkins screen will appear.

2. Select Jenkins data for importing

You may either import Jenkins data from its home location on the Bamboo server, or you may import from a zipped archive of your Jenkins home:

**Importing from the Jenkins home location**

From the Locate Jenkins interface:
1. Click the Source of Jenkins home dropdown menu
2. Select Location on the Bamboo server
3. Enter the path to your Jenkins home directory in the text field
4. Click Next.

You must specify the path to your Jenkins home directory.

**Importing from an archived Jenkins home**

From anywhere within the Bamboo interface:
1. Click the Source of Jenkins home dropdown menu
2. Select Upload a zip archive
3. Click Choose Files. A file manager window will open. Use it to locate your zipped Jenkins home directory
4. Click Next.

When creating your Jenkins zip archive, you need to remove or exclude the userContent and builds directory for each job from the archive before zipping:

1. Make a copy of Jenkins home
2. Remove/exclude the userContent directory
3. Remove/exclude the builds directory
4. Zip the archive.

Bamboo Jenkins Importer supports only ZIP file archives. Other archive formats such as tar and tar.gz are not currently supported.

Once you have selected your Jenkins data and clicked Next, the Jenkins job and pipeline selector will open.

3. Configure Jenkins data for import

The Job and Pipeline selector screen allows you to select and configure which Jenkins import items you would like to import into Bamboo. Import items include Jenkins pipelines and jobs, and the importer will identify how many items were found for processing:
The Jenkins Importer processes both Jenkins pipelines and jobs, but handles each differently:

<table>
<thead>
<tr>
<th>Jenkins Import Item</th>
<th>Description</th>
<th>Bamboo Equivalent</th>
<th>Jenkins Importer Process</th>
</tr>
</thead>
</table>
| Pipeline            | A group of associated jobs linked using a Jenkins pipeline | Plan | • Creates a new Bamboo plan  
• Imports individual pipeline jobs as Bamboo jobs into the new plan |
| Job                 | A stand alone build job | Job | • Imports job into a Bamboo plan with a single associated job within the plan |

**Importing a Jenkins job**

To import a Jenkins job:

1. Locate the relevant Jenkins Import item on the selector screen
2. Ensure the Import Jobs check box is checked
3. Enter a Bamboo Job Name (or leave to accept the default name from Jenkins)
4. Check the Enabled in Bamboo? check box. To disable an imported job, leave the box unchecked. Bamboo will not automatically run a disabled job.

By default, all jobs are selected for importing. To reject a Jenkins job for importation:

1. Locate the relevant Jenkins Import item on the selector screen
2. Uncheck the Import Jobs check box

**Importing a Jenkins pipeline**

To import a Jenkins pipeline, all of the associated jobs must be imported. The importing of individual jobs is described above.

**Changing the imported Bamboo plan or job name**

By default, the Jenkins Importer uses the Jenkins import item name as the default for the Bamboo name. To change the default name:

1. Locate the relevant Jenkins Import item on the selector screen
2. Enter a new name in the Bamboo Plan Name text field

**Existing Bamboo plans**

Existing Bamboo plans are not overwritten when you use the Jenkins Importer. When importing Jenkins data, Bamboo creates a new project called 'Imported from Jenkins' to contain all of the newly imported plans.

**Starting the import**

When you have identified and selected all of the Jenkins import items that you require, click Next at the bottom of the screen. Bamboo will start to import the specified plans and a progress indicator screen will display:
Once importing has finished, the importer results screen will display.

4. Review the importer results

The Importer Results screen shows the success outcome of the import activity for each import item. The three possible success outcomes are:

- Success
- Partial
- Fail

An example of Importer results is seen below.

<table>
<thead>
<tr>
<th>Import</th>
<th>Result</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPLAN_DOCS</td>
<td>PARTIAL</td>
<td>Imported with warnings. See Import log for details.</td>
</tr>
<tr>
<td>DLINK_CODE_CHECK</td>
<td>FAIL</td>
<td>Could not import due to fatal error. See Import log for details.</td>
</tr>
<tr>
<td>SPLAN_DEPLOY</td>
<td>SUCCESS</td>
<td></td>
</tr>
</tbody>
</table>

**Success**

A 'success' result indicates that the Jenkins item was successfully imported into Bamboo. No additional work is required.

**Partial**

A 'partial' result indicates that the import was partially successful, however there may be unmapped configuration or other issues that require attention.

**Fail**

A 'fail' result indicates that the importer was unable to import the Jenkins job or pipeline if the repository type is unsupported, none of the build steps could be converted to tasks or another unknown error occurred.

**The Import log**

In the case of a fail or partial, additional information can be obtained from the Import log, which provides the following:

- The name of the attempted job import
- The severity if the problem/issue. Severity is rated as:
  - Low – warning that might be interesting to the administrator such as how dependencies were imported
  - Medium – unsupported publishers or other configurations that are non-critical to running the build
  - High – unsupported repository or none of the build steps could be imported
  - Fatal – un-handled error that prevents the job from importing at all
- A brief description of the problem/issue.

An example Import Log entry can be seen below:

```
Job name: SPLAN_DOCS
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase UCM Plugin'
```

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
It is possible that an import item has multiple problems/Issues. Where this is the case, the Import Log will identify the severity and brief description for each problem/issue associated with an import item. An example Import Log entry detailing multiple problems/Issues can be seen below:

```
-------------------------------------
Job name: DLINK_CODE_CHECK
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase Plugin'
SEVERITY: HIGH
Requested plugin parameterized-trigger but we don't support it
SEVERITY: HIGH
Requested plugin downstream-ext but we don't support it
SEVERITY: FATAL
Scm cannot be imported
-------------------------------------
```

The import log is accessed by clicking on the Import Log link associated with an import issue, or by clicking on the Download import log file button at the base of the Import Results screen.

**Missing or incompatible plugins**

From time to time, Bamboo may not support particular Jenkins functionality. When this occurs, a great place to look is the Atlassian Marketplace. The Marketplace contains over 120 add-ons and plugins for Bamboo, and you will more than likely find a plugin for your functionality there. If you can’t find what you need in the Marketplace, then consult the ‘Getting help’ section below.

5. View the imported plans

Once you have completed examining the importer results, click on View Plans to examine the imported plans in the Bamboo dashboard. An example of plans imported from Jenkins is seen below:

![Imported plans from Jenkins](image)

Imported plans can now be configured and managed using existing Bamboo methods.

**Getting Help**

**Support**

Help with the Jenkins importer is never far away. The best way to get help is to raise a support ticket directly via the Atlassian support site.

To create a support ticket:

1. Download the import log
Go to [https://support.atlassian.com](https://support.atlassian.com) and select **Create New Issue**
3. Enter a detailed description of your problem within the support ticket
4. Attach the import log and lodge your support ticket
5. Wait to be notified of updates by Email

<td></td>
</tr>
</tbody>
</table>

The Required Dependencies are the functional Jenkins plugins that the Bamboo Jenkins Importer requires to be present. These must be present in your Jenkins instance.

### Using the Jenkins importer

1. Start the importer

You must have administration privileges to run the Jenkins Importer

The Jenkins Importer is accessed from the welcome screen or Administration panel. To start the Jenkins Importer:

**If running Bamboo for the first time**

From the Bamboo Welcome screen:

1. Click **Import from...**
2. Select **Import from Jenkins**.
If already running Bamboo

From anywhere within the Bamboo interface:

1. Click on the Administration tab at the top of the Bamboo interface
2. Scroll down to the System side panel
3. Click on Import from Jenkins.

The Locate Jenkins screen will appear.

2. Select Jenkins data for importing

You may either import Jenkins data from its home location on the Bamboo server, or you may import from a zipped archive of your Jenkins home:

Importing from the Jenkins home location

From the Locate Jenkins interface:

1. Click the Source of Jenkins home dropdown menu
2. Select Location on the Bamboo server
3. Enter the path to your Jenkins home directory in the text field
4. Click Next.

You must specify the path to your Jenkins home directory.

Importing from an archived Jenkins home

From anywhere within the Bamboo interface:

1. Click the Source of Jenkins home dropdown menu
2. Select Upload a zip archive
3. Click Choose Files. A file manager window will open. Use it to locate your zipped Jenkins home directory
4. Click Next.

When creating your Jenkins zip archive, you need to remove or exclude the userContent and builds directory for each job from the archive before zipping:

1. Make a copy of Jenkins home
2. Remove/exclude the userContent directory
3. Remove/exclude the builds directory
4. Zip the archive.

Bamboo Jenkins Importer supports only ZIP file archives. Other archive formats such as tar and tar.gz are not currently supported.

Once you have selected your Jenkins data and clicked Next, the Jenkins job and pipeline selector will open.

3. Configure Jenkins data for import

The Job and Pipeline selector screen allows you to select and configure which Jenkins import items you would like to import into Bamboo. Import items include Jenkins pipelines and jobs, and the importer will identify how many items were found for processing:
The Jenkins Importer processes both Jenkins pipelines and jobs, but handles each differently:

<table>
<thead>
<tr>
<th>Jenkins Import Item</th>
<th>Description</th>
<th>Bamboo Equivalent</th>
<th>Jenkins Importer Process</th>
</tr>
</thead>
</table>
| Pipeline            | A group of associated jobs linked using a Jenkins pipeline | Plan | • Creates a new Bamboo plan  
• Imports individual pipeline jobs as Bamboo jobs into the new plan |
| Job                 | A stand alone build job | Job | • Imports job into a Bamboo plan with a single associated job within the plan |

**Importing a Jenkins job**

To import a Jenkins job:

1. Locate the relevant Jenkins Import item on the selector screen
2. Ensure the **Import Jobs** check box is checked
3. Enter a **Bamboo Job Name** (or leave to accept the default name from Jenkins)
4. Check the **Enabled in Bamboo?** check box. To disable an imported job, leave the box unchecked. Bamboo will not automatically run a disabled job.

By default, all jobs are selected for importing. To reject a Jenkins job for importation:

1. Locate the relevant Jenkins Import item on the selector screen
2. Uncheck the **Import Jobs** check box

**Importing a Jenkins pipeline**

To import a Jenkins pipeline, all of the associated jobs must be imported. The importing of individual jobs is described above.

**Changing the imported Bamboo plan or job name**

By default, the Jenkins Importer uses the Jenkins import item name as the default for the Bamboo name. To change the default name:

1. Locate the relevant Jenkins Import item on the selector screen
2. Enter a new name in the **Bamboo Plan Name** text field

**Existing Bamboo plans**

Existing Bamboo plans are not overwritten when you use the Jenkins Importer. When importing Jenkins data, Bamboo creates a new project called 'Imported from Jenkins' to contain all of the newly imported plans.

**Starting the import**

When you have identified and selected all of the Jenkins import items that you require, click **Next** at the bottom of the screen. Bamboo will start to import the specified plans and a progress indicator screen will display:
Once importing has finished, the importer results screen will display.

4. Review the importer results

The Importer Results screen shows the success outcome of the import activity for each import item. The three possible success outcomes are:

- **Success**
- **Partial**
- **Fail**

An example of Importer results is seen below.

<table>
<thead>
<tr>
<th>Job Name</th>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPLAN_DOCS</td>
<td>PARTIAL</td>
<td>Imported with warnings. See Import log for details</td>
</tr>
<tr>
<td>DLINK_CODE_CHECK</td>
<td>FAIL</td>
<td>Could not import due to fatal error. See Import log for details</td>
</tr>
<tr>
<td>SPLAN_DEPLOY</td>
<td>SUCCESS</td>
<td></td>
</tr>
</tbody>
</table>

**Success**

A **success** result indicates that the Jenkins item was successfully imported into Bamboo. No additional work is required.

**Partial**

A **partial** result indicates that the import was partially successful, however there may be unmapped configuration or other issues that require attention.

**Fail**

A **fail** result indicates that the importer was unable to import the Jenkins job or pipeline if the repository type is unsupported, none of the build steps could be converted to tasks or another unknown error occurred.

**The Import log**

In the case of a fail or partial, additional information can be obtained from the Import log, which provides the following:

- The name of the attempted job import
- The severity if the problem/issue. Severity is rated as:
  - Low – warning that might be interesting to the administrator such as how dependencies were imported
  - Medium – unsupported publishers or other configurations that are non-critical to running the build
  - High – unsupported repository or none of the build steps could be imported
  - Fatal – un-handled error that prevents the job from importing at all
- A brief description of the problem/issue.

An example Import Log entry can be seen below:

```
-------------------------------------------------  
Job name: SPLAN_DOCS  
SEVERITY: HIGH  
Unsupported configuration for plugin 'ClearCase UCM Plugin'  
-------------------------------------------------  
```
It is possible that an import item has multiple problems/issues. Where this is the case, the Import Log will identify the severity and brief description for each problem/issue associated with an import item. An example Import Log entry detailing multiple problems/issues can be seen below:

```
Job name: DLINK_CODE_CHECK
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase Plugin'
SEVERITY: HIGH
Requested plugin parameterized-trigger but we don't support it
SEVERITY: HIGH
Requested plugin downstream-ext but we don't support it
SEVERITY: FATAL
Scm cannot be imported
```

The import log is accessed by clicking on the Import Log link associated with an import issue, or by clicking on the Download import log file button at the base of the Import Results screen.

**Missing or incompatible plugins**

From time to time, Bamboo may not support particular Jenkins functionality. When this occurs, a great place to look is the Atlassian Marketplace. The Marketplace contains over 120 add-ons and plugins for Bamboo, and you will more than likely find a plugin for your functionality there. If you can't find what you need in the Marketplace, then consult the ‘Getting help’ section below.

5. View the imported plans

Once you have completed examining the importer results, click on View Plans to examine the imported plans in the Bamboo dashboard. An example of plans imported from Jenkins is seen below:

![Imported from Jenkins](image)

Imported plans can now be configured and managed using existing Bamboo methods.

**Getting Help**

**Support**

Help with the Jenkins importer is never far away. The best way to get help is to raise a support ticket directly via the Atlassian support site.

To create a support ticket:

1. Download the import log
2. Go to https://support.atlassian.com and select Create New Issue
3. Enter a detailed description of your problem within the support ticket
4. Attach the import log and lodge your support ticket
5. Wait to be notified of updates by Email

</tbody>
</table>

The Required Dependencies are the functional Jenkins plugins that the Bamboo Jenkins Importer requires to be present. These must be present in your Jenkins instance.

Using the Jenkins importer

1. Start the importer

You must have administration privileges to run the Jenkins Importer

The Jenkins Importer is accessed from the welcome screen or Administration panel. To start the Jenkins Importer:

If running Bamboo for the first time

From the Bamboo Welcome screen:

1. Click Import from...
2. Select Import from Jenkins.
If already running Bamboo

From anywhere within the Bamboo interface:
1. Click on the Administration tab at the top of the Bamboo interface
2. Scroll down to the System side panel
3. Click on Import from Jenkins.

The Locate Jenkins screen will appear.

2. Select Jenkins data for importing

You may either import Jenkins data from its home location on the Bamboo server, or you may import from a zipped archive of your Jenkins home:

Importing from the Jenkins home location

From the Locate Jenkins interface:
1. Click the Source of Jenkins home dropdown menu
2. Select Location on the Bamboo server
3. Enter the path to your Jenkins home directory in the text field
4. Click Next.

You must specify the path to your Jenkins home directory.

Importing from an archived Jenkins home

From anywhere within the Bamboo interface:
1. Click the Source of Jenkins home dropdown menu
2. Select Upload a zip archive
3. Click Choose Files. A file manager window will open. Use it to locate your zipped Jenkins home directory
4. Click Next.

When creating your Jenkins zip archive, you need to remove or exclude the userContent and builds directory for each job from the archive before zipping:
1. Make a copy of Jenkins home
2. Remove/exclude the userContent directory
3. Remove/exclude the builds directory
4. Zip the archive.

Bamboo Jenkins Importer supports only ZIP file archives. Other archive formats such as tar and tar.gz are not currently supported.

Once you have selected your Jenkins data and clicked Next, the Jenkins job and pipeline selector will open.

3. Configure Jenkins data for import

The Job and Pipeline selector screen allows you to select and configure which Jenkins import items you would like to import into Bamboo. Import items include Jenkins pipelines and jobs, and the importer will identify how many items were found for processing:
The Jenkins Importer processes both Jenkins pipelines and jobs, but handles each differently:

<table>
<thead>
<tr>
<th>Jenkins Import Item</th>
<th>Description</th>
<th>Bamboo Equivalent</th>
<th>Jenkins Importer Process</th>
</tr>
</thead>
</table>
| Pipeline            | A group of associated jobs linked using a Jenkins pipeline | Plan               | • Creates a new Bamboo plan
|                     |             |                   | • Imports individual pipeline jobs as Bamboo jobs into the new plan |
| Job                 | A stand alone build job | Job               | • Imports job into a Bamboo plan with a single associated job within the plan |

**Importing a Jenkins job**

To import a Jenkins job:

1. Locate the relevant Jenkins Import item on the selector screen
2. Ensure the Import Jobs check box is checked
3. Enter a Bamboo Job Name (or leave to accept the default name from Jenkins)
4. Check the Enabled in Bamboo? check box. To disable an imported job, leave the box unchecked. Bamboo will not automatically run a disabled job.

By default, all jobs are selected for importing. To reject a Jenkins job for importation:

1. Locate the relevant Jenkins Import item on the selector screen
2. Uncheck the Import Jobs check box

**Importing a Jenkins pipeline**

To import a Jenkins pipeline, all of the associated jobs must be imported. The importing of individual jobs is described above.

**Changing the imported Bamboo plan or job name**

By default, the Jenkins Importer uses the Jenkins import item name as the default for the Bamboo name. To change the default name:

1. Locate the relevant Jenkins Import item on the selector screen
2. Enter a new name in the Bamboo Plan Name text field

**Existing Bamboo plans**

Existing Bamboo plans are not overwritten when you use the Jenkins Importer. When importing Jenkins data, Bamboo creates a new project called 'Imported from Jenkins' to contain all of the newly imported plans.

**Starting the import**

When you have identified and selected all of the Jenkins import items that you require, click **Next** at the bottom of the screen. Bamboo will start to import the specified plans and a progress indicator screen will display:
Once importing has finished, the importer results screen will display.

4. Review the importer results

The Importer Results screen shows the success outcome of the import activity for each import item. The three possible success outcomes are:

- **Success**
- **Partial**
- **Fail**

An example of Importer results is seen below.

<table>
<thead>
<tr>
<th>Job Name</th>
<th>Outcome</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPLAN_DOCS</td>
<td>PARTIAL</td>
<td>Imported with warnings. See Import log for details.</td>
</tr>
<tr>
<td>DLINK_CODE_CHECK</td>
<td>FAIL</td>
<td>Could not import due to fatal error. See Import log for details.</td>
</tr>
<tr>
<td>SPLAN_DEPLOY</td>
<td>SUCCESS</td>
<td></td>
</tr>
</tbody>
</table>

**Success**

A `success` result indicates that the Jenkins item was successfully imported into Bamboo. No additional work is required.

**Partial**

A `partial` result indicates that the import was partially successful, however there may be unmapped configuration or other issues that require attention.

**Fail**

A `fail` result indicates that the importer was unable to import the Jenkins job or pipeline if the repository type is unsupported, none of the build steps could be converted to tasks or another unknown error occurred.

**The Import log**

In the case of a fail or partial, additional information can be obtained from the Import log, which provides the following:

- The name of the attempted job import
- The severity if the problem/issue. Severity is rated as:
  - Low – warning that might be interesting to the administrator such as how dependencies were imported
  - Medium – unsupported publishers or other configurations that are non-critical to running the build
  - High – unsupported repository or none of the build steps could be imported
  - Fatal – un-handled error that prevents the job from importing at all
- A brief description of the problem/issue.

An example Import Log entry can be seen below:

```
---------------------------------------------------------------------
Job name: SPLAN_DOCS
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase UCM Plugin'
---------------------------------------------------------------------
```
It is possible that an import item has multiple problems/issues. Where this is the case, the Import Log will identify the severity and brief description for each problem/issue associated with an import item. An example Import Log entry detailing multiple problems/issues can be seen below:

```
---------------------------------------------------
Job name: DLINK_CODE_CHECK
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase Plugin'
SEVERITY: HIGH
Requested plugin parameterized-trigger but we don't support it
SEVERITY: HIGH
Requested plugin downstream-ext but we don't support it
SEVERITY: FATAL
Scm cannot be imported
---------------------------------------------------
```

The import log is accessed by clicking on the Import Log link associated with an import issue, or by clicking on the Download import log file button at the base of the Import Results screen.

**Missing or incompatible plugins**

From time to time, Bamboo may not support particular Jenkins functionality. When this occurs, a great place to look is the Atlassian Marketplace. The Marketplace contains over 120 add-ons and plugins for Bamboo, and you will more than likely find a plugin for your functionality there. If you can't find what you need in the Marketplace, then consult the ‘Getting help’ section below.

5. View the imported plans

Once you have completed examining the importer results, click on View Plans to examine the imported plans in the Bamboo dashboard. An example of plans imported from Jenkins is seen below:

![Imported from Jenkins](image)

Imported plans can now be configured and managed using existing Bamboo methods.

**Getting Help**

**Support**

Help with the Jenkins importer is never far away. The best way to get help is to raise a support ticket directly via the Atlassian support site. To create a support ticket:

1. Download the import log
2. Go to https://support.atlassian.com and select Create New Issue
3. Enter a detailed description of your problem within the support ticket
4. Attach the import log and lodge your support ticket
5. Wait to be notified of updates by Email

The Required Dependencies are the functional Jenkins plugins that the Bamboo Jenkins Importer requires to be present. These must be present in your Jenkins instance.

Using the Jenkins importer

1. Start the importer

You must have administration privileges to run the Jenkins Importer.

The Jenkins Importer is accessed from the welcome screen or Administration panel. To start the Jenkins Importer:

*If running Bamboo for the first time*

From the Bamboo Welcome screen:

1. Click Import from...
2. Select Import from Jenkins.
If already running Bamboo

From anywhere within the Bamboo interface:

1. Click on the Administration tab at the top of the Bamboo interface
2. Scroll down to the System side panel
3. Click on Import from Jenkins.

The Locate Jenkins screen will appear.

2. Select Jenkins data for importing

You may either import Jenkins data from its home location on the Bamboo server, or you may import from a zipped archive of your Jenkins home:

**Importing from the Jenkins home location**

From the Locate Jenkins interface:

1. Click the Source of Jenkins home dropdown menu
2. Select Location on the Bamboo server
3. Enter the path to your Jenkins home directory in the text field
4. Click Next.

You must specify the path to your Jenkins home directory.

**Importing from an archived Jenkins home**

From anywhere within the Bamboo interface:

1. Click the Source of Jenkins home dropdown menu
2. Select Upload a zip archive
3. Click Choose Files. A file manager window will open. Use it to locate your zipped Jenkins home directory
4. Click Next.

When creating your Jenkins zip archive, you need to remove or exclude the userContent and builds directory for each job from the archive before zipping:

1. Make a copy of Jenkins home
2. Remove/exclude the userContent directory
3. Remove/exclude the builds directory
4. Zip the archive.

Bamboo Jenkins Importer supports only ZIP file archives. Other archive formats such as tar and tar.gz are not currently supported.

Once you have selected your Jenkins data and clicked Next, the Jenkins job and pipeline selector will open.

3. Configure Jenkins data for import

The Job and Pipeline selector screen allows you to select and configure which Jenkins import items you would like to import into Bamboo. Import items include Jenkins pipelines and jobs, and the importer will identify how many items were found for processing:
The Jenkins Importer processes both Jenkins pipelines and jobs, but handles each differently:

<table>
<thead>
<tr>
<th>Jenkins Import Item</th>
<th>Description</th>
<th>Bamboo Equivalent</th>
<th>Jenkins Importer Process</th>
</tr>
</thead>
</table>
| Pipeline            | A group of associated jobs linked using a Jenkins pipeline | Plan | • Creates a new Bamboo plan  
• Imports individual pipeline jobs as Bamboo jobs into the new plan |
| Job                 | A stand alone build job | Job | • Imports job into a Bamboo plan with a single associated job within the plan |

**Importing a Jenkins job**

To import a Jenkins job:

1. Locate the relevant Jenkins Import item on the selector screen
2. Ensure the Import Jobs check box is checked
3. Enter a Bamboo Job Name (or leave to accept the default name from Jenkins)
4. Check the Enabled in Bamboo? check box. To disable an imported job, leave the box unchecked. Bamboo will not automatically run a disabled job.

By default, all jobs are selected for importing. To reject a Jenkins job for importation:

1. Locate the relevant Jenkins Import item on the selector screen
2. Uncheck the Import Jobs check box

**Importing a Jenkins pipeline**

To import a Jenkins pipeline, all of the associated jobs must be imported. The importing of individual jobs is described above.

**Changing the imported Bamboo plan or job name**

By default, the Jenkins Importer uses the Jenkins import item name as the default for the Bamboo name. To change the default name:

1. Locate the relevant Jenkins Import item on the selector screen
2. Enter a new name in the Bamboo Plan Name text field

**Existing Bamboo plans**

Existing Bamboo plans are not overwritten when you use the Jenkins Importer. When importing Jenkins data, Bamboo creates a new project called 'Imported from Jenkins' to contain all of the newly imported plans.

**Starting the import**

When you have identified and selected all of the Jenkins import items that you require, click Next at the bottom of the screen. Bamboo will start to import the specified plans and a progress indicator screen will display:
Once importing has finished, the importer results screen will display.

4. Review the importer results

The Importer Results screen shows the success outcome of the import activity for each import item. The three possible success outcomes are:

- Success
- Partial
- Fail

An example of Importer results is seen below.

<table>
<thead>
<tr>
<th>Job Name</th>
<th>Result</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPLAN_DOCS</td>
<td>PARTIAL</td>
<td>Imported with warnings. See Import log for details.</td>
</tr>
<tr>
<td>DLINK_CODE_CHECK</td>
<td>FAIL</td>
<td>Could not import due to fatal error. See Import log for details.</td>
</tr>
<tr>
<td>SPLAN_DEPLOY</td>
<td>SUCCESS</td>
<td></td>
</tr>
</tbody>
</table>

Success

A 'success' result indicates that the Jenkins item was successfully imported into Bamboo. No additional work is required.

Partial

A 'partial' result indicates that the import was partially successful, however there may be unmapped configuration or other issues that require attention.

Fail

A 'fail' result indicates that the importer was unable to import the Jenkins job or pipeline if the repository type is unsupported, none of the build steps could be converted to tasks or another unknown error occurred.

The Import log

In the case of a fail or partial, additional information can be obtained from the Import log, which provides the following:

- The name of the attempted job import
- The severity if the problem/issue. Severity is rated as:
  - Low – warning that might be interesting to the administrator such as how dependencies were imported
  - Medium – unsupported publishers or other configurations that are non-critical to running the build
  - High – unsupported repository or none of the build steps could be imported
  - Fatal – un-handled error that prevents the job from importing at all
- A brief description of the problem/issue.

An example Import Log entry can be seen below:

```
-------------------------------------------------
Job name: SPLAN_DOCS
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase UCM Plugin'
-------------------------------------------------
```
It is possible that an import item has multiple problems/issues. Where this is the case, the Import Log will identify the severity and brief description for each problem/issue associated with an import item. An example Import Log entry detailing multiple problems/issues can be seen below:

```
---
Job name: DLINK_CODE_CHECK
SEVERITY: HIGH
Unsupported configuration for plugin 'ClearCase Plugin'
SEVERITY: HIGH
Requested plugin parameterized-trigger but we don't support it
SEVERITY: HIGH
Requested plugin downstream-ext but we don't support it
SEVERITY: FATAL
Scm cannot be imported
---
```

The import log is accessed by clicking on the Import Log link associated with an import issue, or by clicking on the Download import log file button at the base of the Import Results screen.

### Missing or incompatible plugins

From time to time, Bamboo may not support particular Jenkins functionality. When this occurs, a great place to look is the Atlassian Marketplace. The Marketplace contains over 120 add-ons and plugins for Bamboo, and you will more than likely find a plugin for your functionality there. If you can't find what you need in the Marketplace, then consult the ‘Getting help’ section below.

### 5. View the imported plans

Once you have completed examining the importer results, click on View Plans to examine the imported plans in the Bamboo dashboard. An example of plans imported from Jenkins is seen below:

![Imported from Jenkins](image)

Imported plans can now be configured and managed using existing Bamboo methods.

### Getting Help

#### Support

Help with the Jenkins importer is never far away. The best way to get help is to raise a support ticket directly via the Atlassian support site. To create a support ticket:

1. Download the import log
2. Go to https://support.atlassian.com and select Create New Issue
3. Enter a detailed description of your problem within the support ticket
4. Attach the import log and lodge your support ticket
5. Wait to be notified of updates by Email

Plan directory information REST API

An upcoming Bamboo release will make changes to the on-disk directory structure for BAMBOO_HOME. The changes are required for the improvement of the robustness of some Bamboo features.

As the use cases for this endpoint are somewhat different to the typical usage of Bamboo REST API functionality and the information disclosed is relatively low-risk, we have decided to make the access control strategy configurable using a system property.

For more information about system properties, see Starting Bamboo.

Plan directory information property details

The `bamboo.plan.directory.info.rest` is a system property with the following settings:

- **disabled** (default)
  - The plan directory information REST API is disabled and all requests will be rejected

- **local**
  - The plan directory information REST API is available without authentication to any request originating from localhost

- **anonymous**
  - The plan directory information REST API is accessible anonymously

- **authenticated**
  - The plan directory information REST API is accessible to any authenticated request

- **authenticated-admin**
  - The plan directory information REST API is accessible to any request authenticated as an administrator

API Usage

The API is available at `/rest/api/latest/planDirectoryInfo/{planKey}`. For example:

GET `/rest/api/latest/planDirectoryInfo/PROJ-PLAN`

```json
{"results":
  [{
    "planName": "Plan name",
    "isBranchBuild": false,
    "artifact_plan_roots": ["/opt/bamboo-home/artifacts/PROJ-PLAN"],
    "build_log_job_roots": {
      "PROJ-PLAN-JOB1": ["/opt/bamboo-home/xml-data/builds/PROJ-PLAN-JOB1"],
      "PROJ-PLAN-JOB2": ["/opt/bamboo-home/xml-data/builds/PROJ-PLAN-JOB2"]
    }
  }]
}
```

If no build exists that matches the provided key, an empty list is returned for the results.
**artifact_plan_roots** contains a list of directories that contain artifacts for the plan.

**build_log_job_roots** returns a map of job keys to the directory arrays. That is, each job in the plan is mapped to a list of directories that contain logs and build results for that build.

**Bamboo 5.9 will only ever return single-item lists, but future versions of Bamboo will make changes to the on-disk directory layout and may return lists with multiple entries.**

### Plan directory information REST API v5.14

An upcoming Bamboo release will make changes to the on-disk directory structure for BAMBOO_HOME. The changes are required for the improvement of the robustness of some Bamboo features.

As the use cases for this endpoint are somewhat different to the typical usage of Bamboo REST API functionality and the information disclosed is relatively low-risk, we have decided to make the access control strategy configurable using a system property.

For more information about system properties, see [Starting Bamboo](#).

### Plan directory information property details

The **bamboo.plan.directory.info.rest** is a system property with the following settings:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>disabled</td>
<td>The plan directory information REST API is disabled and all requests will be rejected</td>
</tr>
<tr>
<td>(default)</td>
<td></td>
</tr>
<tr>
<td>local</td>
<td>The plan directory information REST API is available without authentication to any request originating from localhost</td>
</tr>
<tr>
<td>anonymous</td>
<td>The plan directory information REST API is accessible anonymously</td>
</tr>
<tr>
<td>authenticated</td>
<td>The plan directory information REST API is accessible to any authenticated request</td>
</tr>
<tr>
<td>authenticated-admin</td>
<td>The plan directory information REST API is accessible to any request authenticated as an administrator</td>
</tr>
</tbody>
</table>

### API Usage

The API is available at /rest/api/latest/planDirectoryInfo/{planKey}. For example:

GET /rest/api/latest/planDirectoryInfo/PROJ-PLAN

```json
{
  "results":
  [
    {
      "planName": "Plan name",
      "isBranchBuild": false,
      "artifact_plan_roots": ["/opt/bamboo-home/artifacts/PROJ-PLAN"],
      "build_log_job_roots": {
        "PROJ-PLAN-JOB1": ["/opt/bamboo-home/xml-data/builds/PROJ-PLAN-JOB1"],
        "PROJ-PLAN-JOB2": ["/opt/bamboo-home/xml-data/builds/PROJ-PLAN-JOB2"]
      }
    }
  ]
}
```

If no build exists that matches the provided key, an empty list is returned for the results.

**artifact_plan_roots** contains a list of directories that contain artifacts for the plan.

**build_log_job_roots** returns a map of job keys to the directory arrays. That is, each job in the plan is mapped to a list of directories that contain logs and build results for that build.

**Bamboo 5.9 will only ever return single-item lists, but future versions of Bamboo will make changes to the on-disk directory layout**
An upcoming Bamboo release will make changes to the on-disk directory structure for BAMBOO_HOME. The changes are required for the improvement of the robustness of some Bamboo features.

As the use cases for this endpoint are somewhat different to the typical usage of Bamboo REST API functionality and the information disclosed is relatively low-risk, we have decided to make the access control strategy configurable using a system property.

For more information about system properties, see Starting Bamboo.

**Plan directory information property details**

The bamboo.plan.directory.info.rest is a system property with the following settings:

- **disabled** (default)
  The plan directory information REST API is disabled and all requests will be rejected
- **local**
  The plan directory information REST API is available without authentication to any request originating from localhost
- **anonymous**
  The plan directory information REST API is accessible anonymously
- **authenticated**
  The plan directory information REST API is accessible to any authenticated request
- **authenticated-admin**
  The plan directory information REST API is accessible to any request authenticated as an administrator

**API Usage**

The API is available at /rest/api/latest/planDirectoryInfo/{planKey}. For example:

GET /rest/api/latest/planDirectoryInfo/PROJ-PLAN

```json
{"results":
  [{
    "planName": "Plan name",
    "isBranchBuild": false,
    "artifact_plan_roots": ["/opt/bamboo-home/artifacts/PROJ-PLAN"],
    "build_log_job_roots": {
      "PROJ-PLAN-JOB1": ["/opt/bamboo-home/xml-data/builds/PROJ-PLAN-JOB1"],
      "PROJ-PLAN-JOB2": ["/opt/bamboo-home/xml-data/builds/PROJ-PLAN-JOB2"]
    }
  }]
}
```

If no build exists that matches the provided key, an empty list is returned for the results.

- **artifact_plan_roots** contains a list of directories that contain artifacts for the plan.
- **build_log_job_roots** returns a map of job keys to the directory arrays. That is, each job in the plan is mapped to a list of directories that contain logs and build results for that build.

**Bamboo 5.9 will only ever return single-item lists, but future versions of Bamboo will make changes to the on-disk directory layout and may return lists with multiple entries.**

**Security**
As a distributed application, Bamboo's security is important. This page contains links to security-related information in the Bamboo documentation.

Security advisories

For information on how to report a security vulnerability in Bamboo and our policy on security advisories and patches, please read Bamboo security advisories. A full list of security advisories that we have previously issued is also available on that page.

Bamboo permissions

For information on Bamboo's internal security model, i.e. user management and permissions, please see Users and permissions.

Remote agent security considerations

Note the following security implications when enabling remote agents for Bamboo:

- Encryption needs to be enabled on JMS and HTTP connections. The following data is encrypted:
  - login credentials for version control repositories (JMS)
  - build logs (JMS)
  - build artifacts (HTTP)
  See Securing your remote agents.
- Agent authorisation should be enabled, see Agent authentication for more information. If it's not enabled, unauthorized parties will be allowed to install new remote agents, compromising the version control repository credentials.
- Agent secure token should be enabled. If it's not enabled, malicious users can send multiple approval requests for rogue agents which could lead to one of them being mistakenly accepted by a Bamboo administrator. See Security token verification.

As with all services, we strongly recommend that you do not open up agent JMS communication port on a public or untrusted network unless you want to use it. Creating remote agents is Disabling and enabling remote agents support by default.

Bamboo configuration

The following pages contain information on how to configure Bamboo features that can permit/forbid access to the Bamboo application.

- Agent authentication
- Bamboo cookies
- Best practices for Bamboo security
- Securing your remote agents
- Serialization protection methods
- Configuring XSRF protection
- Managing trusted keys
- System-wide encryption
- Repository-stored Bamboo Specs security

Other security resources

Error rendering macro 'sv-contentbylabel' : null

Agent authentication

Bamboo provides ways to verify that remote agents are allowed to connect to the Bamboo server. This provides improved security for sensitive information in Bamboo.

- Bamboo prevents unknown remote agents from connecting to the Bamboo server.
- Remote agents need to be manually approved by an administrator before they can communicate with the Bamboo server in any way.
- You can enable security token verification for additional level of safety.

Remote agent authentication (the manual agent approval) doesn't interfere with security token verification and both features can be enabled or disabled independently.

Note that Elastic agents do not have to be approved.

On this page:
- Authenticating remote agents
- Security token verification
- Notes
## Authenticating remote agents

To enable agent authentication:

1. Click the **icon** in the Bamboo header and choose **Overview**.
2. Then select **Agents** (under ‘Build Resources’).
3. Click **Enable Remote Agent Authentication**, and then **Confirm**.

Now you can approve access for a particular remote agent. To do this, click on the **Agent Authentication** tab (under ‘Remote Agents’).

See [Bamboo remote agent installation guide](#) for details about installing a remote agent.

### Security token verification

Enable token verification to ask all remote agents to provide the token during the initial contact with the Bamboo server. Once you enable the verification, all agents that try to connect to Bamboo without the token are rejected before leaving any trail in Bamboo. By default, the feature is disabled for Bamboo Server.

### Enabling security token verification

To enable security token verification, go to **Bamboo administration > Build resources > Agents**.

When you enable the verification, all agents that already authenticated and connected continue to work. In other words, no running builds should be stopped or broken when the feature gets enabled. However, on server restart or agent restart each agent is required to have a correct token.

There are problems with backwards compatibility. If the feature is enabled, old agents (from older Bamboo versions) will not be able to connect. Users need to download the new agent JAR.

### Viewing the current security token

To view the current token, go to **Bamboo administration > Build resources > Agents > Install remote agent** page.

Each time the feature gets enabled, a new security token is generated, which means that disabling and re-enabling security token verification can be used to reset the token.
Notes

- If the agent’s IP address changes, perhaps because DHCP is being used, then you will have to reapprove the agent when it next tries to connect using that different IP address.
- If you revoke access for a connected agent, the agent will remain connected and will continue to run. However, if the agent is subsequently restarted, it will not be able to connect.
- If you enable remote agent authentication, having previously revoked access for connected agents and disabled remote agent authentication, then you get the option to approve access for all connected agents at once. If you don’t approve this, the agents stay connected and continue to run, but you will need to manually approve them when they next try to connect.

Agent authentication v5.14

Bamboo provides ways to verify that remote agents are allowed to connect to the Bamboo server. This provides improved security for sensitive information in Bamboo.

- Bamboo prevents unknown remote agents from connecting to the Bamboo server.
- Remote agents need to be manually approved by an administrator before they can communicate with the Bamboo server in any way.
- You can enable security token verification for additional level of safety.

Remote agent authentication (the manual agent approval) doesn’t interfere with security token verification an both features can be enabled or disabled independently.

Note that Elastic agents do not have to be approved.

On this page:
- Authenticating remote agents
- Security token verification
- Notes

Related pages:
- Bamboo remote agent installation guide
- Disabling and enabling remote agents support
- Configuring agents

Authenticating remote agents

To enable agent authentication:

1. Click the icon in the Bamboo header and choose Overview.
2. Then select Agents (under ‘Build Resources’).
3. Click Enable Remote Agent Authentication, and then Confirm.

Now you can approve access for a particular remote agent. To do this, click on the Agent Authentication tab (under ‘Remote Agents’).

See Bamboo remote agent installation guide for details about installing a remote agent.

Security token verification

Enable token verification to ask all remote agents to provide the token during the initial contact with the Bamboo server. Once you enable the verification, all agents that try to connect to Bamboo without the token are rejected before leaving any trail in Bamboo. By default, the feature...
is disabled for Bamboo Server.

This feature doesn't affect elastic agents.

Enabling security token verification

To enable security token verification, go to Bamboo administration > Build resources > Agents.

When you enable the verification, all agents that already authenticated and connected continue to work. In other words, no running builds should be stopped or broken when the feature gets enabled. However, on server restart or agent restart each agent is required to have a correct token.

There are problems with backwards compatibility. If the feature is enabled, old agents (from older Bamboo versions) will not be able to connect. Users need to download the new agent JAR.

Viewing the current security token

To view the current token, go to Bamboo administration > Build resources > Agents > Install remote agent page.

Each time the feature gets enabled, a new security token is generated, which means that disabling and re-enabling security token verification can be used to reset the token.

Notes

- If the agent's IP address changes, perhaps because DHCP is being used, then you will have to reapprove the agent when it next tries to connect using that different IP address.
- If you revoke access for a connected agent, the agent will remain connected and will continue to run. However, if the agent is subsequently restarted, it will not be able to connect.
- If you enable remote agent authentication, having previously revoked access for connected agents and disabled remote agent authentication, then you get the option to approve access for all connected agents at once. If you don't approve this, the agents stay connected and continue to run, but you will need to manually approve them when they next try to connect.

Agent authentication v6.0

Bamboo provides ways to verify that remote agents are allowed to connect to the Bamboo server. This provides improved security for sensitive information in Bamboo.

- Bamboo prevents unknown remote agents from connecting to the Bamboo server.
- Remote agents need to be manually approved by an administrator before they can communicate with the Bamboo server in any way.
- You can enable security token verification for additional level of safety.

Remote agent authentication (the manual agent approval) doesn't interfere with security token verification an both features can be enabled or disabled independently.

Note that Elastic agents do not have to be approved.

On this page:

- Authenticating remote agents
- Security token verification
- Notes

Related pages:

- Bamboo remote agent installation guide
- Disabling and enabling remote agents support
- Configuring agents

Authenticating remote agents

To enable agent authentication:

1. Click the icon in the Bamboo header and choose Overview.
2. Then select Agents (under ‘Build Resources’).
3. Click Enable Remote Agent Authentication, and then Confirm.

Now you can approve access for a particular remote agent. To do this, click on the Agent Authentication tab (under ‘Remote Agents’).
See Bamboo remote agent installation guide for details about installing a remote agent.

Remote agents

Remote agents run on computers other than the Bamboo server.

<table>
<thead>

Security token verification

Enable token verification to ask all remote agents to provide the token during the initial contact with the Bamboo server. Once you enable the verification, all agents that try to connect to Bamboo without the token are rejected before leaving any trail in Bamboo. By default, the feature is disabled for Bamboo Server.

Enabling security token verification

To enable security token verification, go to Bamboo administration > Build resources > Agents.

When you enable the verification, all agents that already authenticated and connected continue to work. In other words, no running builds should be stopped or broken when the feature gets enabled. However, on server restart or agent restart each agent is required to have a correct token.

Viewing the current security token

To view the current token, go to Bamboo administration > Build resources > Agents > Install remote agent page.

Each time the feature gets enabled, a new security token is generated, which means that disabling and re-enabling security token verification can be used to reset the token.

Notes

- If the agent’s IP address changes, perhaps because DHCP is being used, then you will have to reapprove the agent when it next tries to connect using that different IP address.
- If you revoke access for a connected agent, the agent will remain connected and will continue to run. However, if the agent is subsequently restarted, it will not be able to connect.
- If you enable remote agent authentication, having previously revoked access for connected agents and disabled remote agent authentication, then you get the option to approve access for all connected agents at once. If you don’t approve this, the agents stay connected and continue to run, but you will need to manually approve them when they next try to connect.

Bamboo cookies

Bamboo uses Seraph, an open source framework, for HTTP cookie authentication.

Authentication cookies

Bamboo uses two cookies:

- The JSESSIONID cookie is created by the application server and used for session tracking purposes.
The ‘remember me’ cookie

The ‘remember me’ cookie is a long-lived HTTP cookie. This cookie can be used to authenticate an unauthenticated session. Bamboo generates this cookie when the user selects the Remember me checkbox on the login page.

Cookie key and value

By default, the cookie key is seraph.bamboo. This key is defined in the BAMBOO-INSTALLATION/webapp/WEB-INF/classes/seraph-config.xml file, in the login.cookie.key parameter.

The cookie contains a unique identifier plus a securely-generated random string.

Use of cookie for authentication

When a user requests a web page, if the request is not already authenticated via session-based authentication or otherwise, Bamboo will match the ‘remember me’ cookie (if present) against the token stored for the user in the Bamboo database (if present).

If the random string matches the value stored in the database and the cookie has not expired, the user is authenticated.

Life of ‘Remember Me’ cookies

You can configure the maximum age of the cookie. To do that you will need to modify the BAMBOO-INSTALLATION/webapp/WEB-INF/classes/seraph-config.xml file and insert the following lines below the other init-param elements:

```
<init-param>
  <param-name>autologin.cookie.age</param-name>
  <param-value>2592000</param-value><!-- 30 days in seconds -->
</init-param>
```

Other cookie usage

There are several cookies in Bamboo that are used for storing basic presentation states, such as the number of log lines to show, which tab was previously selected etc. They are:

<table>
<thead>
<tr>
<th>Cookie</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>AJS.conglomerate.cookie</td>
<td>Track which general tabs are open and closed</td>
</tr>
<tr>
<td>BAMBOO-AGENT-FILTER</td>
<td>Date range to show the builds for agents</td>
</tr>
<tr>
<td>BAMBOO-BUILD-FILTER</td>
<td>Date range to show the builds</td>
</tr>
<tr>
<td>BAMBOO-LOG-REFRESH</td>
<td>Log refresh interval in seconds</td>
</tr>
<tr>
<td>BAMBOO-MAX-DISPLAY-LINES</td>
<td>Maximum # of lines to show on the live logs page</td>
</tr>
<tr>
<td>atlassian.bamboo.dashboard.tab.selected</td>
<td>Which tab is selected on the dashboard</td>
</tr>
<tr>
<td>bamboo.author.view</td>
<td>Which tab is selected on the Authors tab</td>
</tr>
<tr>
<td>bamboo.build.groupby.type</td>
<td>Which time group-by period is used in the reports</td>
</tr>
<tr>
<td>bamboo_dash.display.toggle</td>
<td>The ids of the projects that are expanded on the dashboard</td>
</tr>
</tbody>
</table>
Best practices for Bamboo security

The best way to harden a system is to look at each of the involved systems individually. Contact your company’s security officer or department to find out what security policies you should be using. There are many things to consider, such as the configuration of your underlying operating systems, application servers, database servers, network, firewall, routers, etc. It would be impossible to outline all of them here.

This page contains guidelines on good security practices, to the best of our knowledge.

On this page:

- Configuring the web server
- Configuring the application server
- Configuring the application
- Securing JGit connections
- Configuring system admin access
- Further precautions

Configuring the web server

Please refer to the following guides for system administrators:

- How to configure Apache to lock down the administration interface to those people who really need it. See Using Apache to limit access to the Confluence administration interface for guidance.
- How to reduce the risk of brute force attacks: Enabling or Disabling Captcha for Failed Logins.

Configuring the application server

See the following system administrator guide for general hints on the application server level:

- Tomcat security best practices

Configuring the application

The way you set up Bamboo roles, permissions and processes makes a big difference in the security of your Bamboo site.

Below are some more Bamboo-specific items to consider. None of these provides 100% security. They are measures to reduce impact and to slow down an intruder in case your system does become compromised.

- Restrict the number of users with powerful roles or group memberships. If only one department should have access to particularly sensitive data, then do restrict access to the data to those users. Do not let convenience over-rule security. Do not give all staff access to sensitive data when there is no need.
- Put documented procedures in place for the case of employees leaving the company.
- Perform security audits regularly. Know who can help in case a security breach occurs. Perform ‘what if’ planning exercises. (‘What is the worst thing that could happen if a privileged user’s password were stolen while he’s on vacation? What can we do to minimize damage?’).
- Make sure the Bamboo database user (and all datasource database users) only has the amount of database privileges it really needs.
- Monitor your binaries. If an attacker compromises an account on your system, he will usually try to gain access to more accounts. This is sometimes done by adding malicious code, such as by modifying files on the system. Run routine scripts that regularly verify that no malicious change has been made.
- Disable Bamboo from serving HTML and JavaScript artifacts. Allowing Bamboo to do this creates an XSS vulnerability where HTML and JavaScript artifacts can be executed on the user’s browser. Go to Security settings (under ‘Security’) in the Bamboo admin area, and clear the Resolve artifacts content type by extension checkbox. Such artifacts will then be returned as plain text resources and the user’s browser will handle them as simple text.

Securing JGit connections

Use the bamboo.crypto.trust.jgit.all system property. The default value is "true", which means that the application maintains the old logic when AllTrustingHttpConnectionFactory is used for JGit connections. You can override this property by setting the value to "false", which means that org.eclipse.jgit.transport.http.JDKHttpConnectionFactory will be used for certificate validation.

This feature addresses the issue mentioned in

BAM-16194 - JGit allows Bamboo agents to trust any given certificate

Configuring system admin access
Below are some things to consider specifically related to the system admin role:

- Keep the number of Bamboo administrators extremely low. For example, 3 system administrator accounts should be the maximum.
- The administrators should have separate Bamboo accounts for their administrative roles and for their day to day roles. If John Doe is an administrator, he should have a regular user account without administrator access to do his day to day work (such as configuring build plans). This could be a 'john.doe' account. In addition, he should have an entirely separate account (that cannot be guessed by an outsider and that does not even use his proper name) for administrative work. This account could be 'jane smith' – using a username that is so obscure or fake that no outsider could guess it. This way, even if an attacker singles out the actual person John Doe and gets hold of his password, the stolen account would most likely be John's regular user account, and the attacker cannot perform administrative actions with that account.
- Lock down administrative actions as much as you can. If there is no need for your administrators to perform administrative actions from outside the office, then lock down access to those actions to known IP addresses, for example. See Using Apache to limit access to the Confluence administration interface for guidance.

Further precautions

As another precaution:

- Regularly monitor the above requirements. There are many things that could start out well, but deteriorate over time:
  - A system may start out with just 3 administrators, but over the course of a year this could grow to 30 administrators if no one prevents expansion.
  - Apache administration restrictions may be in place at the start of the year, but when the application server is migrated after a few months, people may forget to apply the rules to the new system.

Again, keep in mind that the above steps may only be a fraction of what could apply to you, depending on your security requirements. Also, keep in mind that none of the above rules can guarantee anything. They just make it harder for an intruder to move quickly.

Securing your remote agents

This page applies to remote agents and not elastic agents. Elastic agents are secured automatically by the Bamboo server and no additional steps are required.

We strongly recommend that you do not enable remote agent installation without securing them on any Bamboo instance accessible from a public or untrusted network. Creating remote agents is disabled by default. If you choose to enable your remote agents without securing them, read Bamboo Security Advisory to understand the security implications.

You can secure your remote agents by configuring them to use SSL (Secure Sockets Layer). This protocol provides a secure mechanism for communication between your Bamboo server and remote agents. The information below describes how to configure your remote agents to use SSL.

On this page:

- Configure your Bamboo server to use SSL
- Special considerations/troubleshooting

Related pages:

- Configuring agents
- Knowledge Base articles

Configure your Bamboo server to use SSL

To instruct your Bamboo server to start using SSL so that agents will be able to authenticate the server, you need to modify the addresses used for communication between the agent and the server.

To configure your Bamboo server to use SSL:
If you are setting up Bamboo for the first time,

1. Launch the Bamboo Setup Wizard and change the protocol of the 'Broker URL' to 'SSL'.
   i.e. `ssl://host:port/`

   Setting up Broker URL during the installation doesn't change the Broker Client URL to the same protocol. You can change the Broker Client URL either directly in the Bamboo GUI (Bamboo administration > Overview > System > General Configuration) or in the bamboo.cfg.xml file. Restart Bamboo to run it with the updated setup.

Or, if you are configuring an existing installation of Bamboo,

1. Shut down your Bamboo server and agents.
2. Change the protocol of your Broker URL and Broker client URL in the bamboo.cfg.xml file to 'SSL'. Note, do not change the address of this URL.

   ```xml
   <property name="bamboo.jms.broker.uri">ssl://myhost:myport</property>
   <property name="bamboo.jms.broker.client.uri">failover:(ssl://myhost:myport)</property>
   ``

3. Start up the Bamboo server.
4. Start up the Bamboo agents. If your agents do not start up, please check that you have set up your certificates correctly.

Special considerations/troubleshooting

On a standard Bamboo installation, the above steps are sufficient to secure your agents. After they're done, Bamboo will automatically set up the key/trust stores and distribute certificates to the agents the moment the first time the agent connects to the server.

If you're using custom SSL setup (e.g. you're running Bamboo with `-Djavax.net.ssl.keyStore=SOMEPATH`), you need to follow the guidelines in Manually securing your remote agents.

The automatic keystore management can be enabled or disabled by adding `-Dbamboo.manage.jms.ssl=true/false` to the server command line. When this variable is present, Bamboo will not decide whether to run automatic key management.

The following files are used by automatic key management:

- The Agent stores the keystore and truststore in `BAMBOO_AGENT_HOME/xml-data/configuration/jmsclient.ks` and `BAMBOO_AGENT_HOME/xml-data/configuration/jmsclient.ts`, respectively.
- Server stores the keystore in `BAMBOO_HOME/xml-data/configuration/broker.ks`

To force generation of new keystores and truststores, simply remove these files. They will be regenerated on the next restart.

Securing your remote agents v5.14

This page applies to remote agents and not elastic agents. Elastic agents are secured automatically by the Bamboo server and no additional steps are required.

We strongly recommend that you do not enable remote agent installation without securing them on any Bamboo instance accessible from a public or untrusted network. Creating remote agents is disabled by default. If you choose to enable your remote agents without securing them, please read this Security Advisory to understand the security implications.

You can secure your remote agents by configuring them to use SSL (Secure Sockets Layer). This protocol provides a secure mechanism for communication between your Bamboo server and remote agents. The information below describes how to configure your remote agents to use SSL.

Configure your Bamboo server to use SSL

To instruct your Bamboo server to start using SSL so that agents will be able to authenticate the server, you need to modify the addresses used for communication between the agent and the server.

To configure your Bamboo server to use SSL:
If you are setting up Bamboo for the first time,

1. Launch the Bamboo Setup Wizard and change the protocol of the 'Broker URL' to 'SSL'.
   i.e. ssl://host:port/

Setting up Broker URL during the installation doesn't change the Broker Client URL to the same protocol. You can change the Broker Client URL either directly in the Bamboo GUI (Bamboo administration > Overview > System > General Configuration) or in the bamboo.cfg.xml file. Restart Bamboo to run it with the updated setup.

Or, if you are configuring an existing installation of Bamboo,

1. Shut down your Bamboo server and agents.
2. Change the protocol of your Broker URL and Broker client URL in the bamboo.cfg.xml file to ‘SSL’. Note, do not change the address of this URL.
   <property name="bamboo.jms.broker.uri">ssl://myhost:myport</property>
   <property name="bamboo.jms.broker.client.uri">failover:(ssl://myhost:myport)</property>
3. Start up the Bamboo server.
4. Start up the Bamboo agents. If your agents do not start up, please check that you have set up your certificates correctly.

Special considerations/troubleshooting

On a standard Bamboo installation, the above steps are sufficient to secure your agents. After they're done, Bamboo will automatically set up the key/trust stores and distribute certificates to the agents the moment the first time the agent connects to the server.

If you're using custom SSL setup (e.g. you're running Bamboo with -Djavax.net.ssl.keyStore=SOMEPATH), you need to follow the guidelines in Manually securing your remote agents.

The automatic keystore management can be enabled or disabled by adding -Dbamboo.manage.jms.ssl=true/false to the server command line. When this variable is present, Bamboo will not decide whether to run automatic key management.

The following files are used by automatic key management:
- The Agent stores the keystore and truststore in BAMBOO_AGENT_HOME/xml-data/configuration/jmsclient.ks and BAMBOO_AGENT_HOME/xml-data/configuration/jmsclient.ts, respectively.
- Server stores the keystore in BAMBOO_HOME/xml-data/configuration/broker.ks

To force generation of new keystores and truststores, simply remove these files. They will be regenerated on the next restart.

Serialization protection methods

For security/compatibility reasons, you can control the way Java classes are filtered during deserialisation. This is particularly important for agent-server communication.

The filtering can be either whitelist- or blacklist-based.

The whitelist is the only recommended option for XStream serialisation. Blacklist (the former default) is scheduled for removal and should only be considered as a temporary fix in case of problems with the whitelist.

You can disable serialization security completely by setting the bamboo.security.serialization.disable system property. This is not recommended for security reasons.

You can set up the serialization protection methods in Bamboo administration > Security > Security settings.

<table>
<thead>
<tr>
<th>Serialization</th>
<th>Description</th>
<th>Options</th>
</tr>
</thead>
</table>
| XStream       | Agent - server messaging | • whitelist (default)  
|               |              | • blacklist (insecure)  
|               |              | • strict blacklist (insecure)  |
| Bandana       | Bamboo custom storage mechanism that can be used by plugins | • blacklist  
|               |              | • strict blacklist (default)  |

Overview of options

The recommended option: whitelist

Whitelist has three sources:
- bundled with Bamboo (can't be modified),
- a list of whitelisted classes can be added into Bamboo home directory,
- plugin vendors can define certain classes as allowed.

A whitelist has higher priority than a blacklist. If a class is blacklisted by Bamboo, but is whitelisted anywhere (by a plugin or via bamboo
home directory settings), then even if we're using the blacklist security setting, the class will still be allowed to be serialized/deserialized. For more information about how to add classes to the whitelist or implement a plugin module, see Bamboo developer documentation.

Blacklist (insecure)

Blacklists are provided by Bamboo and can't be modified by plugin vendors or administrators.

Strict blacklist (insecure)

Strict blacklist restricts a bit more classes than the blacklist. Nevertheless, it's still considered insecure and it can cause problems with some of the plugins.

Configuring XSRF protection

To prevent users being tricked into unintentionally submitting malicious data, Bamboo uses XSRF security protection. Atlassian supported plugins have been updated to support XSRF. XSRF protection is enabled by default for Atlassian Cloud customers and new customers for Bamboo Server, however, if you are using a plugin that is not yet compatible with this security feature, you can disable it.

Please carefully consider the security risks before you disable XSRF protection in your Bamboo installation.

Read more about XSRF (Cross Site Request Forgery) at wikipedia.

To configure XSRF protection:

1. Click the icon in the Bamboo header and choose Overview.
2. Choose Security settings in the left-hand panel.
3. Choose Edit.
4. Uncheck Enable XSRF protection to disable XSRF protection or check it to enable XSRF protection.
5. Choose Save.

Related pages:
- Security
- Best practices for Bamboo security

XSRF protection was introduced in Bamboo 5.3, and is enabled automatically for all existing and new Atlassian Cloud users. Existing Bamboo Server users can enable XSRF protection by following the instructions above and checking Enable XSRF protection.

Is my Bamboo server already protected against XSRF attacks?

<table>
<thead>
<tr>
<th>Customers upgrading...</th>
<th>XSRF protection</th>
</tr>
</thead>
<tbody>
<tr>
<td>... an existing installation of Bamboo 5.2, and earlier, to Bamboo 5.3, and later.</td>
<td>X</td>
</tr>
<tr>
<td>... a new installation of Bamboo Server 5.3, and later.</td>
<td>✓</td>
</tr>
</tbody>
</table>

Managing trusted keys

By default, Bamboo accepts communication from all repository hosts that authenticate with SSH. You can secure communication between Bamboo and repositories by setting up trusted key management.

- Prevent Bamboo from connecting to unauthorized services via SSH.
- Manually authorize SSH key of the repository hosts upon first connection.
- Automatically authorize repository hosts that were added to the trusted keys list.

Trusted keys management is available only for restricted administrators.

Enabling trusted keys management in Bamboo

To enable SSH key management:

1. Go to Administration > Security > Security settings > Global security and permission properties.
2. Select the Manage trusted keys check box.
Results

- The **Trusted keys** configuration page is now available in **Administration > Security**:

Adding and deleting trusted keys in Bamboo

You can manage the authorized public SSH keys in the **Trusted keys** page.

To add a trusted key:

1. Go to **Administration > Security > Trusted keys**.
2. Specify the host URL, for example:

   ```text
   bitbucket.org
   ```

3. Paste the **public** key that you generated for your repository host and click **Add**.
System-wide encryption

As a CI/CD system, Bamboo stores sensitive data used to authenticate to external systems, such as VCS's, issue trackers and deployment targets. To protect this data, Bamboo uses a central encryption service.

Data encrypted at rest

The following data is encrypted:

- variables that include keywords such as "secret" and "password". These variables will also be obfuscated in the UI,
- shared credentials,
- credentials stored in the repository configuration (keys, passwords and passphrases).

This data is encrypted in the database and in the backups.

Encryption of data in transit

Bamboo relies on transport-level encryption for security of data in transit.

In the case of remote agents, this means that Bamboo must be configured with SSL for the JMS and web interfaces. In case of elastic agents, the encrypted tunnel (automatically set up by Bamboo) provides security out of the box.

Encryption algorithm

The data is encrypted with AES algorithm using a key length of 256 bits. Both the key and the initialization vector are automatically generated using a secure random source when first used.

Key storage

The encryption key is stored in the database and on the filesystem. Both the filesystem and the database key parts are required to perform successful decryption.

The key part stored on your filesystem is located under BAMBOO-HOME/xml-data/configuration/cipher.

Data recovery

In case a part of your key is lost, your credentials will no longer be available and nothing can be done to recover them.

System-wide encryption v5.15

As a CI/CD system, Bamboo stores sensitive data used to authenticate to external systems, such as VCS's, issue trackers and deployment targets. To protect this data, Bamboo uses a central encryption service.

Data encrypted at rest

The following data is encrypted:

- variables that include keywords such as "secret" and "password". These variables will also be obfuscated in the UI,
- shared credentials,
- credentials stored in the repository configuration (keys, passwords and passphrases).

This data is encrypted in the database and in the backups.

**Data recovery**

In case a part of your key is lost, your credentials will no longer be available and nothing can be done to recover them.

---

**Security v6.0**

As a distributed application, Bamboo's security is important. This page contains links to security-related information in the Bamboo documentation.

**Security advisories**

For information on how to report a security vulnerability in Bamboo and our policy on security advisories and patches, please read Bamboo security advisories. A full list of security advisories that we have previously issued is also available on that page.

**Bamboo permissions**

For information on Bamboo's internal security model, i.e. user management and permissions, please see Users and permissions.

**Remote agent security considerations**

Note the following security implications when enabling remote agents for Bamboo:

- Encryption needs to be enabled on JMS and HTTP connections. The following data is encrypted:
  - login credentials for version control repositories (JMS)
  - build logs (JMS)
  - build artifacts (HTTP)

  See Securing your remote agents.

- Agent authorisation should be enabled, see Agent authentication for more information. If it's not enabled, unauthorized parties will be allowed to install new remote agents, compromising the version control repository credentials.

- Agent secure token should be enabled. If it's not enabled, malicious users can send multiple approval requests for rogue agents which could lead to one of them being mistakenly accepted by a Bamboo administrator. See Security token verification.

As with all services, we strongly recommend that you do not open up agent JMS communication port on a public or untrusted network unless you want to use it. Creating remote agents is Disabling and enabling remote agents support by default.

**Bamboo configuration**

Bamboo permissions

For information on Bamboo’s internal security model, i.e. user management and permissions, please see Users and permissions.

Remote agent security considerations

Please note the following security implications when enabling remote agents for Bamboo:

- No encryption of data passed between server and agent — this includes data such as:
  - login credentials for version control repositories
  - build logs
  - build artifacts
- No authentication of the agent or server — this could result in unauthorized actions being taken on your system, such as:
  - Unauthorized parties installing new remote agents — version control repository login credentials could be stolen.
  - Unauthorized parties masquerading as a Bamboo server — the unauthorized server could pass malicious code to the agent to run.
  - See Agent authentication for more information.

We strongly recommend that you do not enable remote agent installation on any Bamboo instance accessible from a public or untrusted network. Creating remote agents is Disabling and enabling remote agents support by default.

Repository-stored Bamboo Specs security

To modify security setting for repository-stored Bamboo Specs:

1. Go to
   > Security Settings.
2. Choose from the following settings:

| Enable Repository Stored Specs | This is a global toggle to enable/disable processing of Bamboo Specs projects stored in Bitbucket Server repositories. This feature allows to manage plans and deployments using configuration stored as code in your VCS. Once you enable this feature, you can select which repositories contain Bamboo Specs to be processed, see Enabling repository-stored Bamboo Specs. |
| Enable secure Specs processing | Prevent malicious code execution during Bamboo Specs processing. With this feature enabled the Bamboo Specs code will be executed under security manager with Java applet privileges (no access to file system, networking etc). We strongly recommend to keep this toggle enabled, unless your Bamboo Specs requires more access; for instance, you want to fetch list of repositories from Bitbucket Sever to create a build plan for each of them; or to get of users from LDAP to update plan permissions). |

Repository-stored Bamboo Specs security v6.2

To modify security setting for repository-stored Bamboo Specs:

1. Go to
   > Security Settings.
2. Choose from the following settings:
### Enable Repository Stored Specs

This is a global toggle to enable/disable processing of Bamboo Specs projects stored in Bitbucket Server repositories. This feature allows to manage plans and deployments using configuration stored as code in your VCS. Once you enable this feature, you can select which repositories contain Bamboo Specs to be processed, see [Enabling repository-stored Bamboo Specs](#).

We strongly recommend to keep this toggle enabled, unless your Bamboo Specs requires more access; for instance you need networking to fetch data from external systems.

### Enable secure Specs processing

Prevent malicious code execution during Bamboo Specs processing. With this feature enabled the Bamboo Specs code will be executed under security manager with Java applet privileges (no access to file system, networking etc). We strongly recommend to keep this toggle enabled, unless your Bamboo Specs requires more access; for instance, you want to fetch list of repositories from Bitbucket Server to create a build plan for each of them; or to get of users from LDAP to update plan permissions.

## Repository-stored Bamboo Specs security v6.3

To modify security setting for repository-stored Bamboo Specs:

1. Go to [Security Settings](#).
2. Choose from the following settings:

| Enable Repository Stored Specs | This is a global toggle to enable/disable processing of Bamboo Specs projects stored in Bitbucket Server repositories. This feature allows to manage plans and deployments using configuration stored as code in your VCS. Once you enable this feature, you can select which repositories contain Bamboo Specs to be processed, see [Enabling repository-stored Bamboo Specs](#).
| Enable secure Specs processing | Prevent malicious code execution during Bamboo Specs processing. With this feature enabled the Bamboo Specs code will be executed under security manager with Java applet privileges (no access to file system, networking etc). We strongly recommend to keep this toggle enabled, unless your Bamboo Specs requires more access; for instance, you want to fetch list of repositories from Bitbucket Server to create a build plan for each of them; or to get of users from LDAP to update plan permissions). |

## Repository-stored Bamboo Specs security v6.4

To modify security setting for repository-stored Bamboo Specs:

1. Go to [Security Settings](#).
2. Choose from the following settings:

| Enable Repository Stored Specs | This is a global toggle to enable/disable processing of Bamboo Specs projects stored in Bitbucket Server repositories. This feature allows to manage plans and deployments using configuration stored as code in your VCS. Once you enable this feature, you can select which repositories contain Bamboo Specs to be processed, see [Enabling repository-stored Bamboo Specs](#).
| Enable secure Specs processing | Prevent malicious code execution during Bamboo Specs processing. With this feature enabled the Bamboo Specs code will be executed under security manager with Java applet privileges (no access to file system, networking etc). We strongly recommend to keep this toggle enabled, unless your Bamboo Specs requires more access; for instance, you want to fetch list of repositories from Bitbucket Server to create a build plan for each of them; or to get of users from LDAP to update plan permissions). |

## Advanced actions

This section describes the administrative actions that are performed from outside of the Bamboo administration console.
Integrating Bamboo with Apache HTTP server

Error rendering macro 'viewport-redirect' : null

This page explains how to establish a network topology in which Apache HTTP Server acts as a reverse proxy for Bamboo. Typically, such a configuration would be used when Bamboo is installed in a protected zone 'behind the firewall', and Apache HTTP Server provides a gateway through which users outside the firewall can access Bamboo.

Be aware that Bamboo does not need to run behind a web server, since it is capable of serving web requests directly; to secure Bamboo when run in this way see Securing Bamboo with Tomcat using SSL. Otherwise, if you want to install Bamboo in an environment that incorporates Apache HTTP Server, keep on reading.

About using Apache software

This section has general information pertaining to the use of Apache HTTP Server and Apache Tomcat. It is important that you read this section before proceeding to the steps that follow.

Configuring Tomcat 7

Bamboo ships with an instance of Tomcat 7, the configuration of which is determined by the contents of the server.xml file, which can be found in the conf directory immediately under the Bamboo installation directory. Note that any changes that you make to the server.xml file will be effective upon starting or re-starting Bamboo.

On this page:
- About using Apache software
- Step 1: Configure the Tomcat Connector
- Step 2: Change Bamboo's base URL
- Step 3 (optional): Set a context path for Bamboo
- Step 4: Enable mod_proxy and mod_proxy_http in Apache HTTP Server
- Step 5: Configure mod_proxy to map requests to Bamboo
- Step 6: Configure mod_proxy to disable forward proxying
- Step 7: Allow proxying to Bamboo from everywhere
- Step 8 (optional): Configure Apache HTTP Server for SSL
- A note about application links
- Troubleshooting

Configuring Apache HTTP Server

Since Apache HTTP Server is not an Atlassian product, Atlassian does not guarantee to provide support for its configuration. You should consider the material on this page to be for your information only; use it at your own risk. If you encounter problems with configuring Apache HTTP Server, we recommend that you refer to the Apache HTTP Server Support page.

You may find it helpful to refer to the Apache HTTP Server Documentation, which describes how you can control Apache HTTP Server by changing the contents of the httpd.conf file. The section on Apache Module mod_proxy is particularly relevant. Note that any changes you make to the httpd.conf file will be effective upon starting or re-starting Apache HTTP Server.

This document relates to Apache HTTP Server version 2.4.2; the configuration of other versions may differ.

**Step 1: Configure the Tomcat Connector**

Find the normal (non-SSL) Connector directive in Tomcat’s server.xml file, and add the scheme, proxyName, and proxyPort attributes as shown below. Instead of mycompany.com, set the proxyName attribute to the domain name that Apache HTTP Server will be configured to serve. This informs Bamboo of the domain name and port of the requests that reach it via Apache HTTP Server, and is important to the correct operation of the Bamboo functions that construct URLs.
Note: Apache HTTP Server's `ProxyPreserveHost` directive is another way to have the hostname of the incoming request recognized by Bamboo instead of the hostname at which Bamboo is actually running. However, the `ProxyPreserveHost` directive does not cause the scheme to be properly set. Since we have to alter Tomcat's `Connector` directive anyway, we recommend that you stick with the above-described approach, and don't bother to set the `ProxyPreserveHost` in Apache HTTP Server.

For more information about configuring the Tomcat Connector, refer to the [Apache Tomcat 7.0 HTTP Connector Reference](#).

**Step 2: Change Bamboo's base URL**

After re-starting Bamboo, open a browser window and log in using an administrator account. Go to the Bamboo administration area and click **Server settings** (under 'Settings'), and change **Base URL** to match the proxy URL (the URL that Apache HTTP Server will be serving).

**Step 3 (optional): Set a context path for Bamboo**

By default, Bamboo is configured to run with an empty context path; in other words, from the 'root' of the server's name space. In that default configuration, Bamboo is accessed at:

http://localhost:8085/

It's perfectly fine to run Bamboo with the empty context path as above. Alternatively, you can set a context path by changing the `Context` directive in Tomcat's `server.xml` file:

```xml
<Context path="/bamboo" docBase="${catalina.home}/atlassian-bamboo"
reloaded="false" useHttpOnly="true">
    ....
</Context>
```

If you do set a context path, it is important that the same path be used in **Step 5**, when setting up the `ProxyPass` and `ProxyPassReverse` directives. You should also append the context path to Bamboo's base URL (see **Step 2**).

**Step 4: Enable mod_proxy and mod_proxy_http in Apache HTTP Server**

In the `mod_proxy` documentation, you will read that `mod_proxy` can be used as a forward proxy, or as a reverse proxy (gateway); you want the latter. Where the `mod_proxy` documentation mentions 'origin server', it refers to your Bamboo server. Unless you have a good reason for doing otherwise, load `mod_proxy` and `mod_proxy_http` dynamically, using the `LoadModule` directive; that means un-commenting the following lines in the `httpd.conf` file:

```apache
LoadModule proxy_module modules/mod_proxy.so
LoadModule proxy_http_module modules/mod_proxy_http.so
```

Experienced administrators may be aware of the Apache Connector module, `mod_jk`. Atlassian does not recommend use of the `mod_jk` module with Bamboo, since it has proven itself to be less reliable than `mod_proxy`.
Step 5: Configure mod_proxy to map requests to Bamboo

To configure mod_proxy for use with Bamboo, you need to use the `ProxyPass` and `ProxyPassReverse` directives in Apache HTTP Server's `httpd.conf` file as follows:

```
ProxyPass       / http://localhost:8085/ connectiontimeout=5
                timeout=300
ProxyPassReverse / http://localhost:8085/
```

Suppose Apache HTTP Server is configured to serve the `mycompany.com` domain; then the above directives tell Apache HTTP Server to forward web requests of the form `http://mycompany.com/*` to the Tomcat connector (Bamboo) running on port 8085 on the same machine.

The `connectiontimeout` attribute specifies the number of seconds Apache HTTP Server waits for the creation of a connection to Bamboo.

The `timeout` attribute specifies the number of seconds Apache HTTP Server waits for data to be sent to Bamboo.

If you set up a context path for Bamboo in Step 3, you'll need to use that context path in your `ProxyPass` and `ProxyPassReverse` directives. Suppose your context path is set to `"/bamboo"`, the directives would be as follows:

```
ProxyPass       /bamboo http://localhost:8085/bamboo
                connectiontimeout=5 timeout=300
ProxyPassReverse /bamboo http://localhost:8085/bamboo
```

If Bamboo is to run on a different domain and/or different port, you should use that domain and/or port number in the `ProxyPass` and `ProxyPassReverse` directives; for example, suppose that Bamboo will run on port 9900 on `private.mycompany.com` under the context path `/bamboo`, then you would use the following directives:

```
ProxyPass       /bamboo http://private.mycompany.com:9900/bamboo
                connectiontimeout=5 timeout=300
ProxyPassReverse /bamboo http://private.mycompany.com:9900/bamboo
```

Step 6: Configure mod_proxy to disable forward proxying

If you are using Apache HTTP Server as a reverse proxy only, and not as a forward proxy server, you should turn forward proxying off by including a `ProxyRequests` directive in the `httpd.conf` file, as follows:

```
ProxyRequests Off
```

Step 7: Allow proxying to Bamboo from everywhere

Strictly speaking, this step is unnecessary because access to proxied resources is unrestricted by default. Nevertheless, we explicitly allow access to Bamboo from any host so that this policy will be applied regardless of any subsequent changes to access controls at the global level. Use the `Proxy` directive in the `httpd.conf` file as follows:

```
<Proxy *>
    Order Deny,Allow
    Allow from all
</Proxy>
```

The `Proxy` directive provides a context for the directives that are contained within its delimiting tags. In this case, we specify a wild-card url (the asterisk), which applies the two contained directives to all proxied requests.

The `Order` directive controls the order in which any `Allow` and `Deny` directives are applied. In the above configuration, we specify "Deny, Allow", which tells Apache HTTP Server to apply any `Deny` directives first, and if any match, the request is denied unless it also matches an `Allow` directive. In fact, "Deny, Allow" is the default; we include it merely for the sake of clarity. Note that we specify one `Allow` directive.
which is described below, and don’t specify any Deny directives.

The Allow directive, in this context, controls which hosts can access Bamboo via Apache HTTP Server. Here, we specify that all hosts are allowed access to Bamboo.

**Step 8 (optional): Configure Apache HTTP Server for SSL**

If you want to set up SSL access to Bamboo, take steps 8(a) to 8(d) below. When you are finished, users will be able to make secure connections to Apache HTTP Server; connections between Apache HTTP Server and Bamboo will remain unsecured (not using SSL). If you don’t want to set up SSL access, you can skip this section entirely.

**Note:** It would be possible to set up an SSL connection between Apache HTTP Server and Tomcat (Bamboo), but that configuration is very unusual, and not recommended in most circumstances.

**Step 8(a): Configure the Tomcat Connector for SSL**

Find the normal (non-SSL) Connector directive in Tomcat’s `server.xml` file, and change the redirectPort, scheme and proxyPort attributes as follows:

```xml
<Connector port="8085"
    protocol="HTTP/1.1"
    connectionTimeout="20000"
    useBodyEncodingForURI="true"
    redirectPort="443"
    compression="on"
    
    compressableMimeType="text/html,text/xml,text/plain,text/css,application/json,application/javascript,application/x-javascript"
    secure="true"
    scheme="https"
    proxyName="mycompany.com"
    proxyPort="443" />
```

The redirectPort directive causes Tomcat-initiated redirections to secured resources to use the specified port. Right now, the Bamboo redirectPort configuration of Tomcat does not involve Tomcat-initiated redirections, so the change to redirectPort is redundant. Nevertheless, we suggest that you change it as directed above for the sake of completeness.

**Step 8(b): Set up a virtual host in Apache HTTP Server**

Un-comment the following LoadModule directive in Apache HTTP Server’s `httpd.conf` file:

```bash
LoadModule ssl_module modules/mod_ssl.so
```

Add the following directives to the `httpd.conf` file:

```bash
Listen 443
<VirtualHost *:443>
    SSLEngine On
    SSLCertificateFile  
</VirtualHost>
```

The Listen directive instructs Apache HTTP Server to listen for incoming requests on port 443. Actually, we could omit that directive in this case, since Apache HTTP Server listens for http requests on port 443 by default. Nevertheless, it's good to make one's intentions explicit.
The `VirtualHost` directive encloses a number of child directives that apply only and always to requests that arrive at port 443. Since our `VirtualHost` block does not include a `ServerName` directive, it inherits the server name from the main server configuration.

The `SSLEngine` directive toggles the use of the SSL/TLS Protocol Engine. In this case, we’re using it to turn SSL on for all requests that arrive at port 443.

The `SSLCertificateFile` directive tells Apache HTTP Server where to find the PEM-encoded certificate file for the server.

The `SSLCertificateKeyFile` directive tells Apache HTTP Server where to find the PEM-encoded private key file corresponding to the certificate file identified by the `SSLCertificateFile` directive. Depending on how the certificate file was generated, it may contain a RSA or DSA private key file, making the `SSLCertificateKeyFile` directive redundant; however, Apache strongly discourages that practice. The recommended approach is to separate the certificate and the private key. If the private key is encrypted, Apache HTTP Server will require a pass phrase to be entered when it starts up.

The `ProxyPass` and `ProxyPassReverse` directives should be set up in manner described in Step 5.

For more information about the support for SSL in Apache HTTP Server, refer to the Apache SSL/TLS Encryption manual. In addition, you will find lots of relevant information in the `<apache directory>/conf/extra/httpd-ssl.conf` file, which is included in the standard Apache distribution.

**Step 8(c): Create SSL certificate and key files**

In Step 8(b), you specified `server.crt` and `server.key` as the certificate file and private key file respectively. Those two files must be created before we can proceed. This step assumes that OpenSSL is installed on your server.

Generate a server key file:

```
openssl genrsa -des3 -out server.key 1024
```

You will be asked to provide a password. Make sure that the password is strong because it will form the one real entry point into the SSL encryption set-up. Make a note of the password because you’ll need it when starting Apache HTTP Server later.

Generate a certificate request file (`server.csr`):

```
openssl req -new -key server.key -out server.csr
```

Generate a self-signed certificate (`server.crt`):

```
openssl x509 -req -days 365 -in server.csr -signkey server.key -out server.crt
```

The above command generates a self-signed certificate that is valid for one year. You can use the certificate signing request to purchase a certificate from a certificate authority. For testing purposes though, the self-signed certificate will suffice. Copy the certificate file and private key file to the locations you specified in Step 8(b).

```
cp server.key /usr/local/apache2/conf/
cp server.crt /usr/local/apache2/conf/
```

**Step 8(d): Update the base URL for 'https'**

Open a browser window and log into Bamboo using an administrator account. Go to the Bamboo administration area and click Server settings (under ‘Settings’). Change Base URL to use ‘https’.

**Using a self-signed certificate**

There are two implications of using the self-signed certificate:

- When you access Bamboo in a web browser, you can expect a warning to appear, alerting you that an un-trusted certificate is in use. Before proceeding you will have to indicate to the browser that you trust the certificate.
- When you perform a git clone operation, SSL verification will fail. The SSL verification error message will look something like this:

```
error:14090086:SSL routines:SSL3_GET_SERVER_CERTIFICATE:certificate verify failed while accessing https://justme@mycompany/git/TP/test.git
```

It’s easy to fix. Turn SSL verification off for individual git operations by setting the `GIT_SSL_NO_VERIFY` environment variable. In Unix, you
can set the variable in-line with git commands as follows:

```
GIT_SSL_NO_VERIFY=true git clone https://justme@mycompany/git/TP/test.git
```

In Windows you have to set the variable in a separate shell statement:

```
set GIT_SSL_NO_VERIFY=true
git clone https://justme@mycompany/git/TP/test.git
```

Once you have purchased and installed a signed certificate from a certificate authority, you will no longer have to include the `GIT_SSL_NO_VERIFY` modifier.

A note about application links

When an application link is established between Bamboo and another Atlassian product (e.g. Jira), and Bamboo is operating 'behind' Apache HTTP Server, the link from the other product to Bamboo must be via the proxy URL; that is, the 'reciprocal URL' from, say Jira, to Bamboo must comport with the proxy name and port that you set at Step 1.

Troubleshooting

- On Fedora Core 4, people have reported 'permission denied' errors when trying to get mod_proxy (and mod_jk) working. Disabling SELinux (/etc/selinux/config) apparently fixes this.
- Some users have reported problems with user sessions being hijacked when the `mod_cache` module is enabled. If you have such problems, disable the `mod_cache` module. Note that this module is enabled by default in some Apache HTTP Server version 2 distributions.
- In general, if you are having problems:
  1. Ensure that Bamboo works as expected when running directly from Tomcat on `http://localhost:8085/bamboo`
  2. Watch the log files (usually in /var/log/httpd/ or /var/log/apache2/). Check that you have a `LogLevel` directive in your `httpd.conf`, and turn up logging (`LogLevel debug`) to get more info.

Integrating Bamboo with Apache HTTP server v5.14

This page explains how to establish a network topology in which Apache HTTP Server acts as a reverse proxy for Bamboo. Typically, such a configuration would be used when Bamboo is installed in a protected zone 'behind the firewall', and Apache HTTP Server provides a gateway through which users outside the firewall can access Bamboo.

Be aware that Bamboo does not need to run behind a web server, since it is capable of serving web requests directly; to secure Bamboo when run in this way see Securing Bamboo with Tomcat using SSL. Otherwise, if you want to install Bamboo in an environment that incorporates Apache HTTP Server, keep on reading.

About using Apache software

This section has general information pertaining to the use of Apache HTTP Server and Apache Tomcat. It is important that you read this section before proceeding to the steps that follow.

Configuring Tomcat 7

Bamboo ships with an instance of Tomcat 7, the configuration of which is determined by the contents of the `server.xml` file, which can be found in the `conf` directory immediately under the Bamboo installation directory. Note that any changes that you make to the `server.xml` file will be effective upon starting or re-starting Bamboo.

Configuring Apache HTTP Server

Since Apache HTTP Server is not an Atlassian product, Atlassian does not guarantee to provide support for its configuration. You should consider the material on this page to be for your information only; use it at your own risk. If you encounter problems with configuring Apache HTTP Server, we recommend that you refer to the Apache HTTP Server Support page.

You may find it helpful to refer to the Apache HTTP Server Documentation, which describes how you can control Apache HTTP Server by
changing the contents of the `httpd.conf` file. The section on Apache Module `mod_proxy` is particularly relevant. Note that any changes you make to the `httpd.conf` file will be effective upon starting or re-starting Apache HTTP Server.

This document relates to Apache HTTP Server version 2.4.2; the configuration of other versions may differ.

**Step 1: Configure the Tomcat Connector**

Find the normal (non-SSL) `Connector` directive in Tomcat's `server.xml` file, and add the `scheme`, `proxyName`, and `proxyPort` attributes as shown below. Instead of `mycompany.com`, set the `proxyName` attribute to the domain name that Apache HTTP Server will be configured to serve. This informs Bamboo of the domain name and port of the requests that reach it via Apache HTTP Server, and is important to the correct operation of the Bamboo functions that construct URLs.

```xml
<Connector port="8085" protocol="HTTP/1.1"
  connectionTimeout="20000"
  useBodyEncodingForURI="true"
  redirectPort="8443"
  compression="on"

  compressableMimeType="text/html,text/xml,text/plain,text/css,application/json,application/javascript,application/x-javascript"
  scheme="http"
  proxyName="mycompany.com"
  proxyPort="80" />
```

**Note:** Apache HTTP Server's `ProxyPreserveHost` directive is another way to have the hostname of the incoming request recognized by Bamboo instead of the hostname at which Bamboo is actually running. However, the `ProxyPreserveHost` directive does not cause the scheme to be properly set. Since we have to alter Tomcat's `Connector` directive anyway, we recommend that you stick with the above-described approach, and don't bother to set the `ProxyPreserveHost` in Apache HTTP Server.

For more information about configuring the Tomcat Connector, refer to the Apache Tomcat 7.0 HTTP Connector Reference.

**Step 2: Change Bamboo’s base URL**

After re-starting Bamboo, open a browser window and log in using an administrator account. Go to the Bamboo administration area and click `Server settings` (under 'Settings'), and change `Base URL` to match the proxy URL (the URL that Apache HTTP Server will be serving).

**Step 3 (optional): Set a context path for Bamboo**

By default, Bamboo is configured to run with an empty context path; in other words, from the 'root' of the server's name space. In that default configuration, Bamboo is accessed at:

```
http://localhost:8085/
```

It’s perfectly fine to run Bamboo with the empty context path as above. Alternatively, you can set a context path by changing the `Context` directive in Tomcat's `server.xml` file:

```xml
<Context path="/bamboo" docBase="${catalina.home}/atlassian-bamboo"
  reloadable="false" useHttpOnly="true">
  ....
</Context>
```

If you do set a context path, it is important that the same path be used in **Step 5**, when setting up the `ProxyPass` and `ProxyPassReverse` directives. You should also append the context path to Bamboo’s base URL (see **Step 2**).

**Step 4: Enable `mod_proxy` and `mod_proxy_http` in Apache HTTP Server**

In the `mod_proxy` documentation, you will read that `mod_proxy` can be used as a forward proxy, or as a reverse proxy (gateway); you want the latter. Where the `mod_proxy` documentation mentions 'origin server', it refers to your Bamboo server. Unless you have a good reason for doing otherwise, load `mod_proxy` and `mod_proxy_http` dynamically, using the `LoadModule` directive; that means un-commenting the following lines in the `httpd.conf` file:
LoadModule proxy_module modules/mod_proxy.so
LoadModule proxy_http_module modules/mod_proxy_http.so

Experienced administrators may be aware of the Apache Connector module, `mod_jk`. Atlassian does not recommend use of the `mod_jk` module with Bamboo, since it has proven itself to be less reliable than `mod_proxy`.

**Step 5: Configure mod_proxy to map requests to Bamboo**

To configure `mod_proxy` for use with Bamboo, you need to use the `ProxyPass` and `ProxyPassReverse` directives in Apache HTTP Server’s `httpd.conf` file as follows:

```
ProxyPass        / http://localhost:8085/ connectiontimeout=5
ProxyPassReverse / http://localhost:8085/
```

Suppose Apache HTTP Server is configured to serve the `mycompany.com` domain; then the above directives tell Apache HTTP Server to forward web requests of the form `http://mycompany.com/*` to the Tomcat connector (Bamboo) running on port `8085` on the same machine.

The `connectiontimeout` attribute specifies the number of seconds Apache HTTP Server waits for the creation of a connection to Bamboo.

The `timeout` attribute specifies the number of seconds Apache HTTP Server waits for data to be sent to Bamboo.

If you set up a context path for Bamboo in Step 3, you’ll need to use that context path in your `ProxyPass` and `ProxyPassReverse` directives. Suppose your context path is set to `”/bamboo”`, the directives would be as follows:

```
ProxyPass        /bamboo http://localhost:8085/bamboo
ProxyPassReverse /bamboo http://localhost:8085/bamboo
```

If Bamboo is to run on a different domain and/or different port, you should use that domain and/or port number in the `ProxyPass` and `ProxyPassReverse` directives; for example, suppose that Bamboo will run on port `9900` on `private.mycompany.com` under the context path `/bamboo`, then you would use the following directives:

```
ProxyPass        /bamboo http://private.mycompany.com:9900/bamboo
ProxyPassReverse /bamboo http://private.mycompany.com:9900/bamboo
```

**Step 6: Configure mod_proxy to disable forward proxying**

If you are using Apache HTTP Server as a reverse proxy only, and not as a forward proxy server, you should turn forward proxying off by including a `ProxyRequests` directive in the `httpd.conf` file, as follows:

```
ProxyRequests Off
```

**Step 7: Allow proxying to Bamboo from everywhere**

Strictly speaking, this step is unnecessary because access to proxied resources is unrestricted by default. Nevertheless, we explicitly allow access to Bamboo from any host so that this policy will be applied regardless of any subsequent changes to access controls at the global level. Use the `Proxy` directive in the `httpd.conf` file as follows:

```
The `<Proxy *>` directive provides a context for the directives that are contained within its delimiting tags. In this case, we specify a wild-card URL (the asterisk), which applies the two contained directives to all proxied requests.

The `Order Deny,Allow` directive controls the order in which any `Allow` and `Deny` directives are applied. In the above configuration, we specify "Deny, Allow", which tells Apache HTTP Server to apply any `Deny` directives first, and if any match, the request is denied unless it also matches an `Allow` directive. In fact, "Deny, Allow" is the default; we include it merely for the sake of clarity. Note that we specify one `Allow` directive, which is described below, and don't specify any `Deny` directives.

The `Allow` directive, in this context, controls which hosts can access Bamboo via Apache HTTP Server. Here, we specify that all hosts are allowed access to Bamboo.

**Step 8 (optional): Configure Apache HTTP Server for SSL**

If you want to set up SSL access to Bamboo, take steps 8(a) to 8(d) below. When you are finished, users will be able to make secure connections to Apache HTTP Server; connections between Apache HTTP Server and Bamboo will remain unsecured (not using SSL). If you don't want to set up SSL access, you can skip this section entirely.

**Note:** It would be possible to set up an SSL connection between Apache HTTP Server and Tomcat (Bamboo), but that configuration is very unusual, and not recommended in most circumstances.

**Step 8(a): Configure the Tomcat Connector for SSL**

Find the normal (non-SSL) `Connector` directive in Tomcat's `server.xml` file, and change the `redirectPort`, `scheme` and `proxyPort` attributes as follows:

```xml
<Connector port="8085"
    protocol="HTTP/1.1"
    connectionTimeout="20000"
    useBodyEncodingForURI="true"
    redirectPort="443"
    compression="on"

    compressableMimeType="text/html,text/xml,text/plain,text/css,application/json,application/javascript,application/x-javascript"

    secure="true"
    scheme="https"
    proxyName="mycompany.com"
    proxyPort="443" />
```

The `redirectPort` directive causes Tomcat-initiated redirections to secured resources to use the specified port. Right now, the Bamboo configuration of Tomcat does not involve Tomcat-initiated redirections, so the change to `redirectPort` is redundant. Nevertheless, we suggest that you change it as directed above for the sake of completeness.

**Step 8(b): Set up a virtual host in Apache HTTP Server**

Un-comment the following `LoadModule` directive in Apache HTTP Server's `httpd.conf` file:

```bash
LoadModule ssl_module modules/mod_ssl.so
```

Add the following directives to the `httpd.conf` file:
The `Listen` directive instructs Apache HTTP Server to listen for incoming requests on port 443. Actually, we could omit that directive in this case, since Apache HTTP Server listens for https requests on port 443 by default. Nevertheless, it's good to make one's intentions explicit.

The `VirtualHost` directive encloses a number of child directives that apply only and always to requests that arrive at port 443. Since our `VirtualHost` block does not include a `ServerName` directive, it inherits the server name from the main server configuration.

The `SSLEngine` directive toggles the use of the SSL/TLS Protocol Engine. In this case, we're using it to turn SSL on for all requests that arrive at port 443.

The `SSLCertificateFile` directive tells Apache HTTP Server where to find the PEM-encoded certificate file for the server.

The `SSLCertificateKeyFile` directive tells Apache HTTP Server where to find the PEM-encoded private key file corresponding to the certificate file identified by the `SSLCertificateFile` directive. Depending on how the certificate file was generated, it may contain a RSA or DSA private key file, making the `SSLCertificateKeyFile` directive redundant; however, Apache strongly discourages that practice. The recommended approach is to separate the certificate and the private key. If the private key is encrypted, Apache HTTP Server will require a pass phrase to be entered when it starts up.

The `ProxyPass` and `ProxyPassReverse` directives should be set up in manner described in Step 5.

For more information about the support for SSL in Apache HTTP Server, refer to the Apache SSL/TLS Encryption manual. In addition, you will find lots of relevant information in the `<apache directory>/conf/extra/httpd-ssl.conf` file, which is included in the standard Apache distribution.

**Step 8(c): Create SSL certificate and key files**

In Step 8(b), you specified `server.crt` and `server.key` as the certificate file and private key file respectively. Those two files must be created before we can proceed. This step assumes that OpenSSL is installed on your server.

Generate a server key file:

```
openssl genrsa -des3 -out server.key 1024
```

You will be asked to provide a password. Make sure that the password is strong because it will form the one real entry point into the SSL encryption set-up. Make a note of the password because you'll need it when starting Apache HTTP Server later.

Generate a certificate request file (`server.csr`):

```
openssl req -new -key server.key -out server.csr
```

Generate a self-signed certificate (`server.crt`):

```
openssl x509 -req -days 365 -in server.csr -signkey server.key -out server.crt
```

The above command generates a self-signed certificate that is valid for one year. You can use the certificate signing request to purchase a certificate from a certificate authority. For testing purposes though, the self-signed certificate will suffice. Copy the certificate file and private key file to the locations you specified in Step 8(b).
Step 8(d): Update the base URL for 'https'

Open a browser window and log into Bamboo using an administrator account. Go to the Bamboo administration area and click Server settings (under ‘Settings’). Change Base URL to use ‘https’.

Using a self-signed certificate

There are two implications of using the self-signed certificate:

- When you access Bamboo in a web browser, you can expect a warning to appear, alerting you that an un-trusted certificate is in use. Before proceeding you will have to indicate to the browser that you trust the certificate.
- When you perform a git clone operation, SSL verification will fail.

The SSL verification error message will look something like this:

```
error:14090086:SSL routines:SSL3_GET_SERVER_CERTIFICATE:certificate verify failed while accessing
https://justme@mycompany/git/TP/test.git
```

It’s easy to fix. Turn SSL verification off for individual git operations by setting the `GIT_SSL_NO_VERIFY` environment variable. In Unix, you can set the variable in-line with git commands as follows:

```
git clone GIT_SSL_NO_VERIFY=true https://justme@mycompany/git/TP/test.git
```

In Windows you have to set the variable in a separate shell statement:

```
set GIT_SSL_NO_VERIFY=true
git clone https://justme@mycompany/git/TP/test.git
```

Once you have purchased and installed a signed certificate from a certificate authority, you will no longer have to include the `GIT_SSL_NO_VERIFY` modifier.

A note about application links

When an application link is established between Bamboo and another Atlassian product (e.g. Jira), and Bamboo is operating 'behind' Apache HTTP Server, the link from the other product to Bamboo must be via the proxy URL; that is, the 'reciprocal URL' from, say Jira, to Bamboo must comport with the proxy name and port that you set at Step 1.

Troubleshooting

- On Fedora Core 4, people have reported 'permission denied' errors when trying to get mod_proxy (and mod_jk) working. Disabling SELinux (/etc/selinux/config) apparently fixes this.
- Some users have reported problems with user sessions being hijacked when the mod_cache module is enabled. If you have such problems, disable the mod_cache module. Note that this module is enabled by default in some Apache HTTP Server version 2 distributions.
- In general, if you are having problems:
  1. Ensure that Bamboo works as expected when running directly from Tomcat on `http://localhost:8085/bamboo`
  2. Watch the log files (usually in /var/log/httpd/ or /var/log/apache2/). Check that you have a LogLevel directive in your httpd.conf, and turn up logging (`LogLevel debug`) to get more info.

Integrating Bamboo with Apache HTTP server v6.7

Error rendering macro 'viewport-redirect': null

This page explains how to establish a network topology in which Apache HTTP Server acts as a reverse proxy for Bamboo. Typically, such a configuration would be used when Bamboo is installed in a protected zone 'behind the firewall', and Apache HTTP Server provides a gateway through which users outside the firewall can access Bamboo.

Be aware that Bamboo does not need to run behind a web server, since it is capable of serving web requests directly; to secure Bamboo when run in this way see Securing Bamboo with Tomcat using SSL. Otherwise, if you want to install Bamboo in an environment that incorporates Apache HTTP Server, keep on reading.

About using Apache software

This section has general information pertaining to the use of Apache HTTP Server and Apache Tomcat. It is important that you read this section before proceeding to the steps that follow.

Configuring Tomcat 7

Bamboo ships with an instance of Tomcat 7, the configuration of which is determined by the contents of the server.xml file, which can be found in the conf directory immediately under the Bamboo installation directory. Note that any changes that you make to the server.xml file will be effective upon starting or re-starting Bamboo.

You may also find it helpful to refer to the Apache Tomcat 7.0 Proxy Support HowTo page.
On this page:
- About using Apache software
- Step 1: Configure the Tomcat Connector
- Step 2: Change Bamboo’s base URL
- Step 3 (optional): Set a context path for Bamboo
- Step 4: Enable mod_proxy and mod_proxy_http in Apache HTTP Server
- Step 5: Configure mod_proxy to map requests to Bamboo
- Step 6: Configure mod_proxy to disable forward proxying
- Step 7: Allow proxying to Bamboo from everywhere
- Step 8 (optional): Configure Apache HTTP Server for SSL
- A note about application links
- Troubleshooting

Configuring Apache HTTP Server

Since Apache HTTP Server is not an Atlassian product, Atlassian does not guarantee to provide support for its configuration. You should consider the material on this page to be for your information only; use it at your own risk. If you encounter problems with configuring Apache HTTP Server, we recommend that you refer to the Apache HTTP Server Support page.

You may find it helpful to refer to the Apache HTTP Server Documentation, which describes how you can control Apache HTTP Server by changing the contents of the httpd.conf file. The section on Apache Module mod_proxy is particularly relevant. Note that any changes you make to the httpd.conf file will be effective upon starting or re-starting Apache HTTP Server.

This document relates to Apache HTTP Server version 2.4.2; the configuration of other versions may differ.

Step 1: Configure the Tomcat Connector

Find the normal (non-SSL) Connector directive in Tomcat's server.xml file, and add the scheme, proxyName, and proxyPort attributes as shown below. Instead of mycompany.com, set the proxyName attribute to the domain name that Apache HTTP Server will be configured to serve. This informs Bamboo of the domain name and port of the requests that reach it via Apache HTTP Server, and is important to the correct operation of the Bamboo functions that construct URLs.

```xml
<Connector port="8085"
protocol="HTTP/1.1"
connectionTimeout="20000"
useBodyEncodingForURI="true"
redirectPort="8443"
compression="on"
compressableMimeType="text/html, text/xml, text/plain, text/css, application/json, application/javascript, application/x-javascript"
scheme="http"
proxyName="mycompany.com"
proxyPort="80" />
```

Note: Apache HTTP Server’s ProxyPreserveHost directive is another way to have the hostname of the incoming request recognized by Bamboo instead of the hostname at which Bamboo is actually running. However, the ProxyPreserveHost directive does not cause the scheme to be properly set. Since we have to alter Tomcat’s Connector directive anyway, we recommend that you stick with the above-described approach, and don’t bother to set the ProxyPreserveHost in Apache HTTP Server.

For more information about configuring the Tomcat Connector, refer to the Apache Tomcat 7.0 HTTP Connector Reference.

Step 2: Change Bamboo’s base URL

After re-starting Bamboo, open a browser window and log in using an administrator account. Go to the Bamboo administration area and click Server settings (under ‘Settings’), and change Base URL to match the proxy URL (the URL that Apache HTTP Server will be serving).

Step 3 (optional): Set a context path for Bamboo

By default, Bamboo is configured to run with an empty context path; in other words, from the 'root' of the server's name space. In that default configuration, Bamboo is accessed at:

http://localhost:8085/

It's perfectly fine to run Bamboo with the empty context path as above. Alternatively, you can set a context path by changing the Context dir
ective in Tomcat’s server.xml file:

```xml
  <Context path="/bamboo" docBase="${catalina.home}/atlassian-bamboo"
  reloadable="false" useHttpOnly="true">
    ....
  </Context>
```

If you do set a context path, it is important that the same path be used in Step 5, when setting up the ProxyPass and ProxyPassReverse directives. You should also append the context path to Bamboo’s base URL (see Step 2).

**Step 4: Enable mod_proxy and mod_proxy_http in Apache HTTP Server**

In the mod_proxy documentation, you will read that mod_proxy can be used as a forward proxy, or as a reverse proxy (gateway); you want the latter. Where the mod_proxy documentation mentions ‘origin server’, it refers to your Bamboo server. Unless you have a good reason for doing otherwise, load mod_proxy and mod_proxy_http dynamically, using the LoadModule directive; that means un-commenting the following lines in the httpd.conf file:

```
LoadModule proxy_module modules/mod_proxy.so
LoadModule proxy_http_module modules/mod_proxy_http.so
```

Experienced administrators may be aware of the Apache Connector module, mod_jk. Atlassian does not recommend use of the mod_jk module with Bamboo, since it has proven itself to be less reliable than mod_proxy.

**Step 5: Configure mod_proxy to map requests to Bamboo**

To configure mod_proxy for use with Bamboo, you need to use the ProxyPass and ProxyPassReverse directives in Apache HTTP Server’s httpd.conf file as follows:

```
ProxyPass        / http://localhost:8085/ connectiontimeout=5
                 timeout=300
ProxyPassReverse / http://localhost:8085/
```

Suppose Apache HTTP Server is configured to serve the mycompany.com domain; then the above directives tell Apache HTTP Server to forward web requests of the form http://mycompany.com/* to the Tomcat connector (Bamboo) running on port 8085 on the same machine.

The connectiontimeout attribute specifies the number of seconds Apache HTTP Server waits for the creation of a connection to Bamboo.

The timeout attribute specifies the number of seconds Apache HTTP Server waits for data to be sent to Bamboo.

If you set up a context path for Bamboo in Step 3, you’ll need to use that context path in your ProxyPass and ProxyPassReverse directives. Suppose your context path is set to "/bamboo", the directives would be as follows:

```
ProxyPass        /bamboo http://localhost:8085/bamboo
                 connectiontimeout=5 timeout=300
ProxyPassReverse /bamboo http://localhost:8085/bamboo
```

If Bamboo is to run on a different domain and/or different port, you should use that domain and/or port number in the ProxyPass and ProxyPassReverse directives; for example, suppose that Bamboo will run on port 9900 on private.mycompany.com under the context path /bamboo, then you would use the following directives:

```
ProxyPass        /bamboo http://private.mycompany.com:9900/bamboo
                 connectiontimeout=5 timeout=300
ProxyPassReverse /bamboo http://private.mycompany.com:9900/bamboo
```

**Step 6: Configure mod_proxy to disable forward proxying**
If you are using Apache HTTP Server as a reverse proxy only, and not as a forward proxy server, you should turn forward proxying off by including a `ProxyRequests` directive in the `httpd.conf` file, as follows:

```
ProxyRequests Off
```

**Step 7: Allow proxying to Bamboo from everywhere**

Strictly speaking, this step is unnecessary because access to proxied resources is unrestricted by default. Nevertheless, we explicitly allow access to Bamboo from any host so that this policy will be applied regardless of any subsequent changes to access controls at the global level. Use the `Proxy` directive in the `httpd.conf` file as follows:

```
<Proxy *>
  Order Deny,Allow
  Allow from all
</Proxy>
```

The `Proxy` directive provides a context for the directives that are contained within its delimiting tags. In this case, we specify a wild-card url (the asterisk), which applies the two contained directives to all proxied requests.

The `Order` directive controls the order in which any `Allow` and `Deny` directives are applied. In the above configuration, we specify "Deny, Allow", which tells Apache HTTP Server to apply any `Deny` directives first, and if any match, the request is denied unless it also matches an `Allow` directive. In fact, "Deny, Allow" is the default; we include it merely for the sake of clarity. Note that we specify one `Allow` directive, which is described below, and don't specify any `Deny` directives.

The `Allow` directive, in this context, controls which hosts can access Bamboo via Apache HTTP Server. Here, we specify that all hosts are allowed access to Bamboo.

**Step 8 (optional): Configure Apache HTTP Server for SSL**

If you want to set up SSL access to Bamboo, take steps 8(a) to 8(d) below. When you are finished, users will be able to make secure connections to Apache HTTP Server; connections between Apache HTTP Server and Bamboo will remain unsecured (not using SSL). If you don't want to set up SSL access, you can skip this section entirely.

**Note:** It would be possible to set up an SSL connection between Apache HTTP Server and Tomcat (Bamboo), but that configuration is very unusual, and not recommended in most circumstances.

**Step 8(a): Configure the Tomcat Connector for SSL**

Find the normal (non-SSL) `Connector` directive in Tomcat's `server.xml` file, and change the `redirectPort`, `scheme` and `proxyPort` attributes as follows:

```
<Connector port="8085"
  protocol="HTTP/1.1"
  connectionTimeout="20000"
  useBodyEncodingForURI="true"
  redirectPort="443"
  compression="on"
  
  compressibleMimeType="text/html,text/xml,text/plain,text/css,application/json,application/javascript,application/x-javascript"
  secure="true"
  scheme="https"
  proxyName="mycompany.com"
  proxyPort="443" />
```

The `redirectPort` directive causes Tomcat-initiated redirections to secured resources to use the specified port. Right now, the Bamboo configuration of Tomcat does not involve Tomcat-initiated redirections, so the change to `redirectPort` is redundant. Nevertheless, we suggest that you change it as directed above for the sake of completeness.

**Step 8(b): Set up a virtual host in Apache HTTP Server**
Un-comment the following LoadModule directive in Apache HTTP Server’s httpd.conf file:

```
LoadModule ssl_module modules/mod_ssl.so
```

Add the following directives to the httpd.conf file:

```
Listen 443
<VirtualHost *:443>
  SSLEngine On
  SSLCertificateFile    "/usr/local/apache2/conf/server.crt"
  SSLCertificateKeyFile "/usr/local/apache2/conf/server.key"
  ProxyPass        / http://localhost:7990/ connectiontimeout=5
  timeout=300
  ProxyPassReverse / http://localhost:7990/
</VirtualHost>
```

The **Listen** directive instructs Apache HTTP Server to listen for incoming requests on port 443. Actually, we could omit that directive in this case, since Apache HTTP Server listens for https requests on port 443 by default. Nevertheless, it’s good to make one’s intentions explicit.

The **VirtualHost** directive encloses a number of child directives that apply only and always to requests that arrive at port 443. Since our VirtualHost block does not include a **ServerName** directive, it inherits the server name from the main server configuration.

The **SSLEngine** directive toggles the use of the SSL/TLS Protocol Engine. In this case, we’re using it to turn SSL on for all requests that arrive at port 443.

The **SSLCertificateFile** directive tells Apache HTTP Server where to find the PEM-encoded certificate file for the server.

The **SSLCertificateKeyFile** directive tells Apache HTTP Server where to find the PEM-encoded private key file corresponding to the certificate file identified by the **SSLCertificateFile** directive. Depending on how the certificate file was generated, it may contain a RSA or DSA private key file, making the **SSLCertificateKeyFile** directive redundant; however, Apache strongly discourages that practice. The recommended approach is to separate the certificate and the private key. If the private key is encrypted, Apache HTTP Server will require a pass phrase to be entered when it starts up.

The **ProxyPass** and **ProxyPassReverse** directives should be set up in manner described in Step 5.

For more information about the support for SSL in Apache HTTP Server, refer to the Apache SSL/TLS Encryption manual. In addition, you will find lots of relevant information in the <$>apache directory>/conf/extra/httpd-ssl.conf file, which is included in the standard Apache distribution.

**Step 8(c): Create SSL certificate and key files**

In Step 8(b), you specified `server.crt` and `server.key` as the certificate file and private key file respectively. Those two files must be created before we can proceed. This step assumes that OpenSSL is installed on your server.

Generate a server key file:

```
openssl genrsa -des3 -out server.key 1024
```

You will be asked to provide a password. Make sure that the password is strong because it will form the one real entry point into the SSL encryption set-up. **Make a note of the password because you’ll need it when starting Apache HTTP Server later.**

Generate a certificate request file (server.csr):

```
openssl req -new -key server.key -out server.csr
```

Generate a self-signed certificate (server.crt):

```
openssl x509 -req -days 365 -in server.csr -signkey server.key -out server.crt
```
The above command generates a self-signed certificate that is valid for one year. You can use the certificate signing request to purchase a certificate from a certificate authority. For testing purposes though, the self-signed certificate will suffice. Copy the certificate file and private key file to the locations you specified in Step 8(b).

```bash
cp server.key /usr/local/apache2/conf/
cp server.crt /usr/local/apache2/conf/
```

Step 8(d): Update the base URL for 'https'

Open a browser window and log into Bamboo using an administrator account. Go to the Bamboo administration area and click **Server settings** (under 'Settings'). Change **Base URL** to use 'https'.

**Using a self-signed certificate**

There are two implications of using the self-signed certificate:

- When you access Bamboo in a web browser, you can expect a warning to appear, alerting you that an un-trusted certificate is in use. Before proceeding you will have to indicate to the browser that you trust the certificate.
- When you perform a git clone operation, SSL verification will fail. The SSL verification error message will look something like this:

```plaintext
error:14090086:SSL routines:SSL3_GET_SERVER_CERTIFICATE:certificate verify failed while accessing https://justme@mycompany/git/TP/test.git
```

It's easy to fix. Turn SSL verification off for individual git operations by setting the `GIT_SSL_NO_VERIFY` environment variable. In Unix, you can set the variable in-line with git commands as follows:

```bash
git clone GIT_SSL_NO_VERIFY=true https://justme@mycompany/git/TP/test.git
```

In Windows you have to set the variable in a separate shell statement:

```bash
set GIT_SSL_NO_VERIFY=true
git clone https://justme@mycompany/git/TP/test.git
```

Once you have purchased and installed a signed certificate from a certificate authority, you will no longer have to include the `GIT_SSL_NO_VERIFY` modifier.

**A note about application links**

When an application link is established between Bamboo and another Atlassian product (e.g. Jira), and Bamboo is operating 'behind' Apache HTTP Server, the link from the other product to Bamboo must be via the proxy URL; that is, the 'reciprocal URL' from, say Jira, to Bamboo must comport with the proxy name and port that you set at Step 1.

**Troubleshooting**

- On **Fedora Core 4**, people have reported 'permission denied' errors when trying to get mod_proxy (and mod_jk) working. Disabling SELinux (/etc/selinux/config) apparently fixes this.
- Some users have reported problems with user sessions being hijacked when the `mod_cache` module is enabled. If you have such problems, disable the `mod_cache` module. Note that this module is enabled by default in some Apache HTTP Server version 2 distributions.
- In general, if you are having problems:
  1. Ensure that Bamboo works as expected when running directly from Tomcat on `http://localhost:8085/bamboo`
  2. Watch the log files (usually in `/var/log/httpd/` or `/var/log/apache2/`). Check that you have a `LogLevel` directive in your `httpd.conf`, and turn up logging (e.g. `LogLevel debug`) to get more info.

**Securing Bamboo with Apache using SSL**

If you want to set up SSL access to Bamboo, follow steps 1 to 4 below. When you are finished, users will be able to make secure connections to Apache HTTP Server; connections between Apache HTTP Server and Bamboo will remain unsecured (not using SSL).

**Note:**

- The steps on this page would normally be performed after **Integrating Bamboo with Apache HTTP Server**.
- It would be possible to set up an SSL connection between Apache HTTP Server and Tomcat (Bamboo), but that configuration is very unusual, and not recommended in most circumstances.

**Step 1: Configure the Tomcat Connector for SSL**

Find the normal (non-SSL) Connector directive in Tomcat's `server.xml` file, and change the `redirectPort`, `scheme` and `proxyPort` attributes as follows:
Step 1: Configure the Tomcat Connector for SSL

```xml
<Connector port="8085"
    protocol="HTTP/1.1"
    connectionTimeout="20000"
    useBodyEncodingForURI="true"
    redirectPort="443"
    compression="on"

    compressableMimeType="text/html,text/xml,text/plain,text/css,application/json,application/javascript,application/x-javascript"
    secure="true"
    scheme="https"
    proxyName="mycompany.com"
    proxyPort="443" />
```

The `redirectPort` directive causes Tomcat-initiated redirections to secured resources to use the specified port. Right now, the Bamboo configuration of Tomcat does not involve Tomcat-initiated redirections, so the change to `redirectPort` is redundant. Nevertheless, we suggest that you change it as directed above for the sake of completeness.

Step 2: Set up a virtual host in Apache HTTP Server

Un-comment the following LoadModule directive in Apache HTTP Server's `httpd.conf` file:

```sh
LoadModule ssl_module modules/mod_ssl.so
```

Add the following directives to the `httpd.conf` file:

```sh
Listen 443
<VirtualHost *:443>
    SSLEngine On
    SSLCertificateFile  "/usr/local/apache2/conf/server.crt"
    SSLCertificateKeyFile  "/usr/local/apache2/conf/server.key"
    ProxyPass        / http://localhost:8085/ connectiontimeout=5
    timeout=300
    ProxyPassReverse / http://localhost:8085/
</VirtualHost>
```

The `Listen` directive instructs Apache HTTP Server to listen for incoming requests on port 443. Actually, we could omit that directive in this case, since Apache HTTP Server listens for `https` requests on port 443 by default. Nevertheless, it’s good to make one’s intentions explicit.

The `VirtualHost` directive encloses a number of child directives that apply only and always to requests that arrive at port 443. Since our `VirtualHost` block does not include a `ServerName` directive, it inherits the server name from the main server configuration.

The `SSLEngine` directive toggles the use of the SSL/TLS Protocol Engine. In this case, we're using it to turn SSL on for all requests that arrive at port 443.
The `SSLCertificateFile` directive tells Apache HTTP Server where to find the PEM-encoded certificate file for the server.

The `SSLCertificateKeyFile` directive tells Apache HTTP Server where to find the PEM-encoded private key file corresponding to the certificate file identified by the `SSLCertificateFile` directive. Depending on how the certificate file was generated, it may contain a RSA or DSA private key file, making the `SSLCertificateKeyFile` directive redundant; however, Apache strongly discourages that practice. The recommended approach is to separate the certificate and the private key. If the private key is encrypted, Apache HTTP Server will require a pass phrase to be entered when it starts up.

The `ProxyPass` and `ProxyPassReverse` directives should be set up in the manner described in Step 5 of the Integrating Bamboo with Apache HTTP server page.

For more information about the support for SSL in Apache HTTP Server, refer to the Apache SSL/TLS Encryption manual. In addition, you will find lots of relevant information in the `<apache directory>/conf/extra/httpd-ssl.conf` file, which is included in the standard Apache distribution.

### Step 3: Create SSL certificate and key files

In Step 2, you specified `server.crt` and `server.key` as the certificate file and private key file respectively. Those two files must be created before we can proceed. This step assumes that OpenSSL is installed on your server.

Generate a server key file:

```
openssl genrsa -des3 -out server.key 2048
```

You will be asked to provide a password. Make sure that the password is strong because it will form the one real entry point into the SSL encryption set-up. **Make a note of the password because you’ll need it when starting Apache HTTP Server later.**

Generate a certificate request file (`server.csr`):

```
openssl req -new -key server.key -out server.csr
```

Generate a self-signed certificate (`server.crt`):

```
openssl x509 -req -days 365 -in server.csr -signkey server.key -out server.crt
```

The above command generates a self-signed certificate that is valid for one year. You can use the certificate signing request to purchase a certificate from a certificate authority. For testing purposes though, the self-signed certificate will suffice. Copy the certificate file and private key file to the locations you specified in Step 2.

```
cp server.key /usr/local/apache2/conf/
cp server.crt /usr/local/apache2/conf/
```

### Step 4: Update the base URL for 'https'

Open a browser window and log into Bamboo using an administrator account. Go to the Bamboo administration area and click **Server settings** (under ‘Settings’). Change **Base URL** to use ‘https’.

### Using a self-signed certificate

There are two implications of using the self-signed certificate:

- When you access Bamboo in a web browser, you can expect a warning to appear, alerting you that an un-trusted certificate is in use. Before proceeding you will have to indicate to the browser that you trust the certificate.
- When you perform a git clone operation, SSL verification will fail.

The SSL verification error message will look something like this:

```
error:14090086:SSL routines:SSL3_GET_SERVER_CERTIFICATE:certificate verify failed while accessing https://justme@mycompany/git/TP/test.git
```

It’s easy to fix. Turn SSL verification off for individual git operations by setting the `GIT_SSL_NO_VERIFY` environment variable. In Unix, you can set the variable in-line with git commands as follows:
1. Generate a self-signed certificate

Self-signed certificates are useful where you require encryption but do not need to verify the website identity. They are commonly used for testing and on internal corporate networks (intranets).

Users may receive a warning that the site is untrusted and have to "accept" the certificate before they can access the site. This usually will only occur the first time they access the site.

The following approach to creating a certificate uses Java's `keytool`, for Java 1.6. Other tools for generating certificates are available.

To generate a self-signed certificate:

- Log in with the user account that Bamboo will run under, and run the following command:

  Windows
  
  "$JAVA_HOME%/bin/keytool" -genkey -alias tomcat -keyalg RSA

  Linux, MacOS and Unix
  
  "$JAVA_HOME/bin/keytool -genkey -alias tomcat -keyalg RSA

  This will create (if it doesn't already exist) a new .keystore file located in the home directory of the user you used to run the keytool command.

Note the following:

- When running the keytool command you will be prompted with: What is your first and last name?

  You must enter the fully qualified hostname of the server running Bamboo. This is the name you would type in your web browser after "http://" (no port number) to access your Bamboo installation. The qualified host name should match the base URL you have set in Bamboo (without the port number).

- The keytool utility will also prompt you for two passwords: the keystore password and the key password for Tomcat.

  You must use the same value for both passwords, and the value must be either:

1. "changeit", which is the default value Tomcat expects, or any other value, but you must also specify it in `conf/server.xml` by adding the following attribute to the `<Connector/>` tag:

    `keystorePass="<password value>"`
2. Configure HTTPS in Tomcat

To configure HTTPS in Tomcat:

- Edit `conf/server.xml` and, at the bottom, before the `<Service>` tag, add this section (or uncomment it if it already exists):

```xml
<Connector port="8443"
    maxHttpHeaderSize="8192"
    SSLEnabled="true"
    maxThreads="150"
    minSpareThreads="25"
    maxSpareThreads="75"
    enableLookups="false"
    disableUploadTimeout="true"
    useBodyEncodingForURI="true"
    acceptCount="100"
    scheme="https"
    secure="true"
    clientAuth="false"
    sslProtocol="TLS" />
```

This enables SSL access on port 8443 (the default for HTTPS is 443, but 8443 is used instead of 443 to avoid conflicts).

Exporting the self-signed certificate

If Bamboo will run as the user who ran the `keytool --genkey` command, you do not need to export the certificate. You may need to export the self-signed certificate, so that you can import it into a different keystore, if Bamboo will not be run as the user executing `keytool --genkey`. You can do so with the following command:

**Windows**

```
"%JAVA_HOME%\bin\keytool" -export -alias tomcat -file file.cer
```

**Linux, MacOS and Unix**

```
$JAVA_HOME/bin/keytool -export -alias tomcat -file file.cer
```

If you generate the certificate as one user and run Bamboo as another, you'll need to do the certificate export as the generating user and the import as the target user.

Requesting a CA certificate

Digital certificates that are issued by trusted 3rd party CAs (Certification Authorities) provide verification that your website does indeed represent your company.

When running Bamboo in a production environment, you will need a certificate issued by a CA, such as VeriSign, DigiCert or Thawte. The instructions below are adapted from the Tomcat documentation.

First, you will generate a local certificate and create a 'certificate signing request' (CSR) based on that certificate. You then submit the CSR to your chosen certificate authority. The CA will use that CSR to generate a certificate for you.

1. Use Java's `keytool` utility to generate a local certificate, as described in the section above.
2. Use the `keytool` utility to generate a CSR, replacing the text `<MY_KEYSTORE_FILENAME>` with the path to and file name of the .keystore file generated for your local certificate:

   **Windows**

   ```
   "%JAVA_HOME%\bin\keytool" -certreq -keyalg RSA -alias tomcat -file certreq.csr -keystore <MY_KEYSTORE_FILENAME>
   ```

   **Linux, MacOS and Unix**

   ```
   $JAVA_HOME/bin/keytool -certreq -keyalg RSA -alias tomcat -file certreq.csr -keystore <MY_KEYSTORE_FILENAME>
   ```
$JAVA_HOME/bin/keytool -certreq -keyalg RSA -alias tomcat -file certreq.csr -keystore <MY_KEYSTORE_FILENAME>

3. Submit the generated file called certreq.csr to your chosen certificate authority. Refer to the documentation on the CA's website to find out how to do this.
4. The CA will send you a certificate.
5. Import the new certificate into your local keystore. Assuming your certificate is called "file.cer" whether obtained from a CA or self-generated, the following command will add the certificate to the keystore:

   **Windows**
   
   "$JAVA_HOME/bin/keytool" -import -alias tomcat -file file.cer

   **Linux, MacOS and Unix**
   
   $JAVA_HOME/bin/keytool -import -alias tomcat -file file.cer

**Troubleshooting**

Here are some troubleshooting tips if you are using a self-signed key created by keytool, or a CA certificate, as described above.

When you enter "https://localhost:8443" in your browser, if you get a message such as "Cannot establish a connection to the server at localhost:8443", look for error messages in your logs/catalina.out log file. Here are some possible errors with explanations:

**SSL + Apache + IE problems**

Some people have reported errors when uploading attachments over SSL using IE. This is due to an IE bug, and can be fixed in Apache by setting:

```
BrowserMatch "MSIE.*" 
   nokeepalive ssl-unclean-shutdown 
   downgrade-1.0 force-response-1.0
```

Google has plenty more on this.

**Can't find the keystore**

java.io.FileNotFoundException: /home/user/.keystore (No such file or directory)

This indicates that Tomcat cannot find the keystore. The keytool utility creates the keystore as a file called .keystore in the current user's home directory. For Unix/Linux the home directory is likely to be /home/username. For Windows it is likely to be C:\User\<UserName>.

Make sure you are running Bamboo as the same user who created the keystore. If this is not the case, or if you are running Bamboo on Windows as a service, you will need to specify where the keystore file is in conf/server.xml. Add the following attribute to the connector tag you uncommented:

```
keystoreFile="<location of keystore file>"
```

**Incorrect password**

java.io.IOException: Keystore was tampered with, or password was incorrect

You used a different password than "changeit". You must either use "changeit" for both the keystore password and for the key password for Tomcat, or if you want to use a different password, you must specify it using the keystorePass attribute of the Connector tag, as described above.

**Passwords don't match**

java.io.IOException: Cannot recover key

You specified a different value for the keystore password and the key password for Tomcat. Both passwords must be the same.

**Wrong certificate**
javax.net.ssl.SSLException: No available certificate corresponds to the SSL cipher suites which are enabled.

If the Keystore has more than one certificate, Tomcat will use the first returned unless otherwise specified in the SSL Connector in `conf/server.xml`.

Add the `keyAlias` attribute to the Connector tag you uncommented, with the relevant alias, for example:

```xml
<Connector port="8443" 
    maxHttpHeaderSize="8192"
    maxThreads="150"
    minSpareThreads="25"
    maxSpareThreads="75"
    enableLookups="false"
    disableUploadTimeout="true"
    useBodyEncodingForURI="true"
    acceptCount="100"
    scheme="https"
    secure="true"
    clientAuth="false"
    sslProtocol="TLS"
    keystoreFile="/opt/local/.keystore"
    keystorePass="removed"
    keyAlias="tomcat"/>
```

Using Apache Portable Runtime

APR uses a different SSL engine, and you will see an exception like this in your logs

```
SEVERE: Failed to initialize connector [Connector[HTTP/1.1-8443]]
LifecycleException: Protocol handler initialization failed: java.lang.Exception: No Certificate file specified or invalid file format
```

The reason for this is that the APR Connector uses OpenSSL and cannot use the keystore in the same way. You can rectify this in one of two ways:

**Use the Http11Protocol to handle SSL connections**

Edit the `server.xml` so that the SSL Connector tag you just uncommented specifies the `Http11Protocol` instead of the APR protocol:

```xml
<Connector port="8443" 
    maxHttpHeaderSize="8192"
    SSLEnabled="true"
    keystoreFile="${user.home}/.keystore"
    maxThreads="150"
    enableLookups="false"
    disableUploadTimeout="true"
    acceptCount="100"
    scheme="https"
    secure="true"
    clientAuth="false"
    sslProtocol="TLS"
    useBodyEncodingForURI="true" />
```

Configure the Connector to use the APR protocol

This is only possible if you have PEM encoded certificates and private keys. If you have used OpenSSL to generate your key, then you will have these PEM encoded files - in all other cases contact your certificate provider for assistance.
Enabling client authentication

To enable client authentication in Tomcat, ensure that the value of the clientAuth attribute in your Connector element of your Tomcat's server.xml file is true.

```
<Connector ...
    clientAuth="true"
    ... />
```

For more information about Connector element parameters, please refer to the 'SSL Support' section of the Tomcat 6.0 documentation.

Wrong certificate type

If the certificate from the CA is in PKCS12 format, add the keystoreType attribute to the SSL Connector in conf/server.xml.

```
keystoreFile="/opt/local/wildcard_atlassian_com.p12"
keystorePass="removed"
keystoreType="PKCS12"/
```

Certificate chain is incomplete

If the root certificate and intermediary certificate(s) aren't imported into the keystore before the entity/domain certificate, you will see the following error:

```
[root@dev atlas]# /usr/java/jdk1.7.0_17/bin/keytool -import -alias tomcat -file my_entity_cert.crt
Enter keystore password:
keytool error: java.lang.Exception: Failed to establish chain from reply
```

Most likely, the CA sent a compressed file containing several certificates. The import order matters so you must import the root certificate first, followed by one or many intermediate certificates, followed lastly by the entity/domain certificate. There are many resources online that provide guidance for certificate installation for Tomcat (Java-based) web servers using keytool.

Securing Bamboo with Tomcat using SSL v5.14

This page is intended for administrators setting up Bamboo for a small team. It describes how to enable HTTPS (HTTP over SSL) access for Tomcat, the webserver distributed with Bamboo, using a self-signed certificate. You should consider doing this, and making secure access mandatory, if Bamboo will be internet-facing and usernames, passwords and other proprietary data may be at risk.

If you are setting up a production instance you should consider using a CA certificate, briefly described below.

Note that you can set up Bamboo to run behind a web server, such as Apache HTTP Server. To secure Bamboo with HTTPS, when Apache HTTP Server acts as a reverse proxy for Bamboo, see Integrating Bamboo with Apache HTTP Server.

Please note that Atlassian Support will refer SSL-related support to the issuing authority for the certificate. The documentation on this page is for reference only.
1. Generate a self-signed certificate

Self-signed certificates are useful where you require encryption but do not need to verify the website identity. They are commonly used for testing and on internal corporate networks (intranets).

Users may receive a warning that the site is untrusted and have to "accept" the certificate before they can access the site. This usually will only occur the first time they access the site.

The following approach to creating a certificate uses Java's keytool, for Java 1.6. Other tools for generating certificates are available.

To generate a self-signed certificate:

- Log in with the user account that Bamboo will run under, and run the following command:

<table>
<thead>
<tr>
<th>Windows</th>
<th>&quot;%JAVA_HOME%\bin\keytool&quot; -genkey -alias tomcat -keyalg RSA</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux, MacOS and Unix</td>
<td>$JAVA_HOME/bin/keytool -genkey -alias tomcat -keyalg RSA</td>
</tr>
</tbody>
</table>

This will create (if it doesn't already exist) a new .keystore file located in the home directory of the user you used to run the keytool command.

Note the following:

- When running the keytool command you will be prompted with: What is your first and last name?

  You must enter the fully qualified hostname of the server running Bamboo. This is the name you would type in your web browser after 'http://' (no port number) to access your Bamboo installation. The qualified host name should match the base URL you have set in Bamboo (without the port number).

- The keytool utility will also prompt you for two passwords: the keystore password and the key password for Tomcat.

  You must use the same value for both passwords, and the value must be either:
  
  1. "changeit", which is the default value Tomcat expects, or
  2. any other value, but you must also specify it in conf/server.xml by adding the following attribute to the <Connector/> tag: keystorePass="<password value>"

2. Configure HTTPS in Tomcat

To configure HTTPS in Tomcat:

- Edit conf/server.xml and, at the bottom, before the </Service> tag, add this section (or uncomment it if it already exists):
Exporting the self-signed certificate

If Bamboo will run as the user who ran the `keytool --genkey` command, you do not need to export the certificate.

You may need to export the self-signed certificate, so that you can import it into a different keystore, if Bamboo will not be run as the user executing `keytool --genkey`. You can do so with the following command:

**Windows**

```
keytool --genkey -export -alias tomcat -file file.cer
```

**Linux, MacOS and Unix**

```
keytool --genkey -export -alias tomcat -file file.cer
```

If you generate the certificate as one user and run Bamboo as another, you'll need to do the certificate export as the generating user and the import as the target user.

Requesting a CA certificate

Digital certificates that are issued by trusted 3rd party CAs (Certification Authorities) provide verification that your website does indeed represent your company.

When running Bamboo in a production environment, you will need a certificate issued by a CA, such as VeriSign, DigiCert or Thawte. The instructions below are adapted from the Tomcat documentation.

First, you will generate a local certificate and create a 'certificate signing request' (CSR) based on that certificate. You then submit the CSR to your chosen certificate authority. The CA will use that CSR to generate a certificate for you.

1. Use Java's `keytool` utility to generate a local certificate, as described in the section above.
2. Use the `keytool` utility to generate a CSR, replacing the text `<MY_KEYSTORE_FILENAME>` with the path to and file name of the .keystore file generated for your local certificate:

**Windows**

```
keytool -certreq -keyalg RSA -alias tomcat -file certreq.csr -keystore <MY_KEYSTORE_FILENAME>
```

**Linux, MacOS and Unix**

```
keytool -certreq -keyalg RSA -alias tomcat -file certreq.csr -keystore <MY_KEYSTORE_FILENAME>
```

3. Submit the generated file called `certreq.csr` to your chosen certificate authority. Refer to the documentation on the CA's website to find out how to do this.
4. The CA will send you a certificate.
5. Import the new certificate into your local keystore. Assuming your certificate is called "file.cer" whether obtained from a CA or self-generated, the following command will add the certificate to the keystore:
Troubleshooting

Here are some troubleshooting tips if you are using a self-signed key created by keytool, or a CA certificate, as described above.

When you enter "https://localhost:8443/" in your browser, if you get a message such as "Cannot establish a connection to the server at localhost:8443", look for error messages in your logs/catalina.out log file. Here are some possible errors with explanations:

**SSL + Apache + IE problems**

Some people have reported errors when uploading attachments over SSL using IE. This is due to an IE bug, and can be fixed in Apache by setting:

```sh
BrowserMatch !".MSIE."
nokeepalive ssl-unclean-shutdown
downgrade-1.0 force-response-1.0
```

Google has plenty more on this.

**Can't find the keystore**

java.io.FileNotFoundException: /home/user/.keystore (No such file or directory)

This indicates that Tomcat cannot find the keystore. The keytool utility creates the keystore as a file called .keystore in the current user's home directory. For Unix/Linux the home directory is likely to be /home/username. For Windows it is likely to be C:\User\<UserName>.

Make sure you are running Bamboo as the same user who created the keystore. If this is not the case, or if you are running Bamboo on Windows as a service, you will need to specify where the keystore file is in conf/server.xml. Add the following attribute to the connector tag you uncommented:

```xml
keystoreFile="<location of keystore file>"
```

**Incorrect password**

java.io.IOException: Keystore was tampered with, or password was incorrect

You used a different password than "changeit". You must either use "changeit" for both the keystore password and for the key password for Tomcat, or if you want to use a different password, you must specify it using the keystorePass attribute of the Connector tag, as described above.

**Passwords don't match**

java.io.IOException: Cannot recover key

You specified a different value for the keystore password and the key password for Tomcat. Both passwords must be the same.

**Wrong certificate**

javax.net.ssl.SSLException: No available certificate corresponds to the SSL cipher suites which are enabled.

If the Keystore has more than one certificate, Tomcat will use the first returned unless otherwise specified in the SSL Connector in conf/server.xml.

Add the keyAlias attribute to the Connector tag you uncommented, with the relevant alias, for example:
Using Apache Portable Runtime

APR uses a different SSL engine, and you will see an exception like this in your logs

SEVERE: Failed to initialize connector [Connector[HTTP/1.1-8443]]
LifecycleException: Protocol handler initialization failed: java.lang.Exception: No Certificate file specified or invalid file format

The reason for this is that the APR Connector uses OpenSSL and cannot use the keystore in the same way. You can rectify this in one of two ways:
Use the Http11Protocol to handle SSL connections

Edit the server.xml so that the SSL Connector tag you just uncommented specifies the Http11Protocol instead of the APR protocol:

```xml
<Connector port="8443"
    maxHttpHeaderSize="8192"
    SSLEnabled="true"
    keystoreFile="${user.home}/.keystore"
    maxThreads="150"
    enableLookups="false"
    disableUploadTimeout="true"
    acceptCount="100"
    scheme="https"
    secure="true"
    clientAuth="false"
    sslProtocol="TLS"
    useBodyEncodingForURI="true" />
```

Configure the Connector to use the APR protocol

This is only possible if you have PEM encoded certificates and private keys. If you have used OpenSSL to generate your key, then you will have these PEM encoded files - in all other cases contact your certificate provider for assistance.
Enabling client authentication

To enable client authentication in Tomcat, ensure that the value of the `clientAuth` attribute in your `Connector` element of your Tomcat's `server.xml` file is `true`.

```xml
<Connector port="8443" maxThreads="200" scheme="https" secure="true" SSLEnabled="true"
SSLCertificateFile="${user.home}/certificate.pem"
SSLCertificateKeyFile="${user.home}/key.pem"
clientAuth="optional" SSLProtocol="TLSv1"/>
```

For more information about `Connector` element parameters, please refer to the 'SSL Support' section of the Tomcat 6.0 documentation.

Wrong certificate type

If the certificate from the CA is in PKCS12 format, add the `keystoreType` attribute to the SSL Connector in `conf/server.xml`.

```xml
keyStoreFile="/opt/local/wildcard_atlassian_com.p12"
keyStorePass="removed"
keystoreType="PKCS12"/
```

Certificate chain is incomplete

If the root certificate and intermediary certificate(s) aren't imported into the keystore before the entity/domain certificate, you will see the following error:

```
[root@dev atlas]# /usr/java/jdk1.7.0_17/bin/keytool -import -alias tomcat -file my_entity_cert.crt
Enter keystore password: 
keytool error: java.lang.Exception: Failed to establish chain from reply
```

Most likely, the CA sent a compressed file containing several certificates. The import order matters so you must import the root certificate first, followed by one or many intermediate certificates, followed lastly by the entity/domain certificate. There are many resources online that provide guidance for certificate installation for Tomcat (Java-based) web servers using keytool.

Securing Bamboo with Tomcat using SSL v6.1

This page is intended for administrators setting up Bamboo for a small team. It describes how to enable HTTPS (HTTP over SSL) access for Tomcat, the webserver distributed with Bamboo, using a self-signed certificate. You should consider doing this, and making secure access mandatory, if Bamboo will be internet-facing and usernames, passwords and other proprietary data may be at risk.

If you are setting up a production instance you should consider using a CA certificate, briefly described below.

Note that you can set up Bamboo to run behind a web server, such as Apache HTTP Server. To secure Bamboo with HTTPS, when Apache HTTP Server acts as a reverse proxy for Bamboo, see Integrating Bamboo with Apache HTTP Server.

Please note that Atlassian Support will refer SSL-related support to the issuing authority for the certificate. The documentation on this page is for reference only.
1. Generate a self-signed certificate

Self-signed certificates are useful where you require encryption but do not need to verify the website identity. They are commonly used for testing and on internal corporate networks (intranets).

Users may receive a warning that the site is untrusted and have to "accept" the certificate before they can access the site. This usually will only occur the first time they access the site.

The following approach to creating a certificate uses Java's keytool, for Java 1.6. Other tools for generating certificates are available.

To generate a self-signed certificate:

- Log in with the user account that Bamboo will run under, and run the following command:

  **Windows**
  ```
  "%JAVA_HOME%\bin\keytool" -genkey -alias tomcat -keyalg RSA
  ```

  **Linux, MacOS and Unix**
  ```
  $JAVA_HOME/bin/keytool -genkey -alias tomcat -keyalg RSA
  ```

  This will create (if it doesn't already exist) a new .keystore file located in the home directory of the user you used to run the keytool command.

  Note the following:

  - When running the keytool command you will be prompted with: What is your first and last name?
    
    You **must** enter the **fully qualified hostname** of the server running Bamboo. This is the name you would type in your web browser after `http://` (no port number) to access your Bamboo installation. The qualified host name should match the base URL you have set in Bamboo (without the port number).

  - The keytool utility will also prompt you for two passwords: the keystore password and the key password for Tomcat.
    
    You **must** use the same value for both passwords, and the value **must** be either:

    1. "changeit", which is the default value Tomcat expects, or
    2. any other value, but you must also specify it in `conf/server.xml` by adding the following attribute to the `<Connector/>` tag:
    ```xml
    <Connector keystorePass="<password value>"/>
    ```

2. Configure HTTPS in Tomcat

To configure HTTPS in Tomcat:

- Edit `conf/server.xml` and, at the bottom, before the `</Service>` tag, add this section (or uncomment it if it already exists):
This enables SSL access on port 8443 (the default for HTTPS is 443, but 8443 is used instead of 443 to avoid conflicts).

**Exporting the self-signed certificate**

If Bamboo will run as the user who ran the `keytool --genkey` command, you do not need to export the certificate.

You may need to export the self-signed certificate, so that you can import it into a different keystore, if Bamboo will not be run as the user executing `keytool --genkey`. You can do so with the following command:

**Windows**

```
"%JAVA_HOME%\bin\keytool" -export -alias tomcat -file file.cer
```

**Linux, MacOS and Unix**

```
$JAVA_HOME/bin/keytool -export -alias tomcat -file file.cer
```

If you generate the certificate as one user and run Bamboo as another, you'll need to do the certificate export as the generating user and the import as the target user.

**Requesting a CA certificate**

Digital certificates that are issued by trusted 3rd party CAs (Certification Authorities) provide verification that your website does indeed represent your company.

When running Bamboo in a production environment, you will need a certificate issued by a CA, such as VeriSign, DigiCert or Thawte. The instructions below are adapted from the Tomcat documentation.

First, you will generate a local certificate and create a 'certificate signing request' (CSR) based on that certificate. You then submit the CSR to your chosen certificate authority. The CA will use that CSR to generate a certificate for you.

1. Use Java's `keytool` utility to generate a local certificate, as described in the section above.
2. Use the `keytool` utility to generate a CSR, replacing the text `<MY_KEYSTORE_FILENAME>` with the path to and file name of the .keystore file generated for your local certificate:

   **Windows**

   ```
   "%JAVA_HOME%\bin\keytool" -certreq -keyalg RSA -alias tomcat -file certreq.csr -keystore <MY_KEYSTORE_FILENAME>
   ```

   **Linux, MacOS and Unix**

   ```
   $JAVA_HOME/bin/keytool -certreq -keyalg RSA -alias tomcat -file certreq.csr -keystore <MY_KEYSTORE_FILENAME>
   ```

3. Submit the generated file called `certreq.csr` to your chosen certificate authority. Refer to the documentation on the CA's website to find out how to do this.
4. The CA will send you a certificate.
5. Import the new certificate into your local keystore. Assuming your certificate is called "file.cer" whether obtained from a CA or self-generated, the following command will add the certificate to the keystore:

**Windows**

```
"%JAVA_HOME%\bin\keytool" -import -alias tomcat -file file.cer
```

**Linux, MacOS and Unix**

```
$JAVA_HOME/bin/keytool -import -alias tomcat -file file.cer
```

### Troubleshooting

Here are some troubleshooting tips if you are using a self-signed key created by keytool, or a CA certificate, as described above.

When you enter "https://localhost:8443/" in your browser, if you get a message such as "Cannot establish a connection to the server at localhost:8443", look for error messages in your log file. Here are some possible errors with explanations:

**SSL + Apache + IE problems**

Some people have reported errors when uploading attachments over SSL using IE. This is due to an IE bug, and can be fixed in Apache by setting:

```
BrowserMatch ".*MSIE.*" \
  nokeepalive ssl-unclean-shutdown \
  downgrade-1.0 force-response-1.0
```

Google has plenty more on this.

**Can't find the keystore**

```
java.io.FileNotFoundException: /home/user/.keystore (No such file or directory)
```

This indicates that Tomcat cannot find the keystore. The keytool utility creates the keystore as a file called .keystore in the current user's home directory. For Unix/Linux the home directory is likely to be /home/<username>. For Windows it is likely to be C:\User\<UserName>.

Make sure you are running Bamboo as the same user who created the keystore. If this is not the case, or if you are running Bamboo on Windows as a service, you will need to specify where the keystore file is in conf/server.xml. Add the following attribute to the connector tag you uncommented:

```
keystoreFile="<location of keystore file>"
```

**Incorrect password**

```
java.io.IOException: Keystore was tampered with, or password was incorrect
```

You used a different password than "changeit". You must either use "changeit" for both the keystore password and for the key password for Tomcat, or if you want to use a different password, you must specify it using the keystorePass attribute of the Connector tag, as described above.

**Passwords don't match**

```
java.io.IOException: Cannot recover key
```

You specified a different value for the keystore password and the key password for Tomcat. Both passwords must be the same.

**Wrong certificate**

```
javax.net.ssl.SSLException: No available certificate corresponds to the SSL cipher suites which are enabled.
```

If the Keystore has more than one certificate, Tomcat will use the first returned unless otherwise specified in the SSL Connector in conf/server.xml. Add the keyAlias attribute to the Connector tag you uncommented, with the relevant alias, for example:
Using Apache Portable Runtime

APR uses a different SSL engine, and you will see an exception like this in your logs:

```
SEVERE: Failed to initialize connector [Connector[HTTP/1.1-8443]]
LifecycleException: Protocol handler initialization failed: java.lang.Exception: No Certificate file specified or invalid file format
```

The reason for this is that the APR Connector uses OpenSSL and cannot use the keystore in the same way. You can rectify this in one of two ways:

1. Use the Http11Protocol to handle SSL connections
2. Configure the Connector to use the APR protocol

**Using the Http11Protocol**

Edit the server.xml so that the SSL Connector tag you just uncommented specifies the Http11Protocol instead of the APR protocol:

```
<Connector port="8443"
    maxHttpHeaderSize="8192"
    SSLEnabled="true"
    keystoreFile="${user.home}/.keystore"
    maxThreads="150"
    enableLookups="false"
    disableUploadTimeout="true"
    acceptCount="100"
    scheme="https"
    secure="true"
    clientAuth="false"
    sslProtocol="TLS"
    useBodyEncodingForURI="true" />
```

**Configuring the APR Protocol**

This is only possible if you have PEM encoded certificates and private keys. If you have used OpenSSL to generate your key, then you will have these PEM encoded files - in all other cases contact your certificate provider for assistance.
<Connector port="8443"
    maxThreads="200"
    scheme="https"
    secure="true"
    SSLEnabled="true"
    SSLCertificateFile="${user.home}/certificate.pem"
    SSLCertificateKeyFile="${user.home}/key.pem"
    clientAuth="optional"
    SSLProtocol="TLSv1"/>

**Enabling client authentication**

To enable client authentication in Tomcat, ensure that the value of the `clientAuth` attribute in your `Connector` element of your Tomcat's `server.xml` file is `true`.

```xml
<Connector ...
    clientAuth="true"
    ... />
```

For more information about `Connector` element parameters, please refer to the 'SSL Support' section of the Tomcat 6.0 documentation.

**Wrong certificate type**

If the certificate from the CA is in PKCS12 format, add the `keystoreType` attribute to the SSL Connector in `conf/server.xml`.

```xml
keyStoreFile="/opt/local/wildcard_atlassian_com.p12"
keyStorePass="removed"
keystoreType="PKCS12"/
```

**Certificate chain is incomplete**

If the root certificate and intermediary certificate(s) aren't imported into the keystore before the entity/domain certificate, you will see the following error:

```
[root@dev atlas]# /usr/java/jdk1.7.0_17/bin/keytool -import -alias tomcat -file my_entity_cert.crt
Enter keystore password:
keytool error: java.lang.Exception: Failed to establish chain from reply
```

Most likely, the CA sent a compressed file containing several certificates. The import order matters so you must import the root certificate first, followed by one or many intermediate certificates, followed lastly by the entity/domain certificate. There are many resources online that provide guidance for certificate installation for Tomcat (Java-based) web servers using keytool.

**Disabling SSH access to elastic instances**

By default, SSH (Secure Shell) access is enabled for elastic instances, the first time that you use Elastic Bamboo. Access rules for the Amazon Elastic Compute Cloud (EC2) are managed by 'security groups' in the Amazon Web Services Console. You can disable SSH access for your elastic instances by changing the EC2 access rules to remove the 'SSH' Connection Method from the 'elasticbamboo' security group.

For instructions on changing the EC2 access rules for Elastic Bamboo, please read the Elastic Bamboo Security document.

**Changing Bamboo's root context path**

There are various reasons why you may wish to change Bamboo's context path. Two of those are:

- You are running Bamboo behind a proxy.
- You have another Atlassian application, or Java web application, available at the same hostname and context path as Bamboo, and are experiencing login problems.
Changing the context path for Bamboo:

1. Navigate to the directory where you are running Bamboo from. This is the install directory that you extracted Bamboo to, not Bamboo home.
2. Stop Bamboo. This can be done using /bin/stop-bamboo.bat on Windows or /bin/stop-bamboo.sh on OSX or Linux.
3. Edit conf/server.xml and find the element below:

   ```xml
   <Context path="" docBase="$(catalina.home)/atlassian-bamboo" reloadable="false" useHttpOnly="true"/>
   ```

   Update the `path` attribute to reflect the context path that you want Bamboo to be accessible at, e.g. "/bamboo":

   ```xml
   <Context path="/bamboo" docBase="$(catalina.home)/atlassian-bamboo" reloadable="false" useHttpOnly="true"/>
   ```

   Then save the file.

4. Start Bamboo using /bin/start-bamboo.bat on Windows or /bin/start-bamboo.sh on OSX or Linux.

   Bamboo should now be available at the same host as before under the new context path. For example a server that was at http://localhost:8085 will now be reachable at http://localhost:8085/bamboo.

5. Once Bamboo has started, go to the administration area and click General Configuration (under ‘System’). Add the new context path to your base URL:

   ```text
   https://my-bamboo-hostname:8085/bamboo
   ```

6. Click Save.

**Bamboo + Apache**

Note that if you are running Bamboo behind Apache:

- You will need to make sure that the host or context path that Bamboo is exposed on is not also being used by another web application that is listening on a different port.
- If you have updated the Bamboo context path using the steps outlined above, you will need to update your Apache configuration, as described in Integrating Bamboo with Apache HTTP Server.

### Collecting analytics for Bamboo

We are continuously working to improve Bamboo. Data about how you use Bamboo helps us do that. We have updated our Privacy Policy so that we may collect usage data automatically unless you disable collection. The data we collect includes information about the systems on which your installation of Bamboo is operating and the features you use in Bamboo.

For more details, see our Privacy Policy, in particular the ‘Analytics Information from Downloadable Products’ section.

See also our End User Agreement.

### How to change data collection settings?

You can opt in to, or out of, data collection at any time. A Bamboo admin can change the data collection settings by going to

> Analytics.
How is data collected?

We use the Atlassian Analytics plugin to collect event data in Bamboo. Analytics logs are stored locally and then periodically uploaded to a secure location.

Collecting analytics for Bamboo v5.14

We are continuously working to improve Bamboo. Data about how you use Bamboo helps us do that. We have updated our Privacy Policy so that we may collect usage data automatically unless you disable collection. The data we collect includes information about the systems on which your installation of Bamboo is operating and the features you use in Bamboo.

For more details, see our Privacy Policy, in particular the 'Analytics Information from Downloadable Products' section. See also our End User Agreement.

How to change data collection settings?

You can opt in to, or out of, data collection at any time. A Bamboo admin can change the data collection settings by going to Analytics (under 'Settings') in the Bamboo admin area.

How is data collected?

We use the Atlassian Analytics plugin to collect event data in Bamboo. Analytics logs are stored locally and then periodically uploaded to a secure location.

Collecting analytics for Bamboo v6.1

We are continuously working to improve Bamboo. Data about how you use Bamboo helps us do that. We have updated our Privacy Policy so that we may collect usage data automatically unless you disable collection. The data we collect includes information about the systems on which your installation of Bamboo is operating and the features you use in Bamboo.

For more details, see our Privacy Policy, in particular the 'Analytics Information from Downloadable Products' section. See also our End User Agreement.

How to change data collection settings?

You can opt in to, or out of, data collection at any time. A Bamboo admin can change the data collection settings by going to Analytics.

Bamboo Instance Health check

Bamboo provides a set of tools that you can use to monitor the health of your instance, as well as to identify the root cause when the instance is not performing as expected.

It's recommended that you look at the status of the health check tools after you install Bamboo or when you need to troubleshoot your setup.

To access the health check tools, go to Overview > System > Troubleshooting and support tools. Then choose the Health Checks tab.

Instance Health is a functionality provided by a built-in Support Tools Plugin. For more information, see Instance Health.

Bamboo Instance Health check types

Bamboo Embedded database
Checks if the instance is connected to an HSQL database.

**Bamboo MySQL Max Allowed Packet**
Checks if the max_allowed_packet variable in your MySQL database is appropriate.

**Bamboo MySQL Character Set**
Checks if the character set used by the tables, columns and database defaults in your MySQL database is correct.

**Bamboo MySQL Collation**
Checks if the collation used by the tables, columns and database defaults in your MySQL database is correct.

**Bamboo MySQL InnoDB Log File Size**
Checks if the innodb_log_file_size variable in your MySQL database is appropriate.

---

**Bamboo Embedded database**
This check verifies if the instance is connected to an HSQL database.

The HSQL database is provided for evaluating Bamboo and is not supported as a production database. To keep your data safe, migrate to a production database once you finish the evaluation and before moving the instance to production.

For more information about how to move to a supported database, see [Moving your Bamboo data to a different database](#).

---

**Bamboo Embedded database v5.14**
This check verifies if the instance is connected to an HSQL database.

The HSQL database is provided for evaluating Bamboo and is not supported as a production database. To keep your data safe, migrate to a production database once you finish the evaluation and before moving the instance to production.

For more information about how to move to a supported database, see [Moving your Bamboo data to a different database](#).

---

**Bamboo Embedded database v6.4**
This check verifies if the instance is connected to an H2 database.

The H2 database is provided for evaluating Bamboo and is not supported as a production database. To keep your data safe, migrate to a production database once you finish the evaluation and before moving the instance to production.

For more information about how to move to a supported database, see [Moving your Bamboo data to a different database](#).

---

**.e v6.3**
This check verifies if the instance is connected to an H2 database.

The H2 database is provided for evaluating Bamboo and is not supported as a production database. To keep your data safe, migrate to a production database once you finish the evaluation and before moving the instance to production.

For more information about how to move to a supported database, see [Moving your Bamboo data to a different database](#).

---

**Bamboo MySQL Max Allowed Packet**
This check verifies if the max_allowed_packet variable in your MySQL database is appropriate.

If the packet size limit is too small, it may cause problems with saving build results to the database.

For more information about the packet size limit, see:

- [Unable to Save Build Results to the Database due to Error ‘Packet for query is too large’](#)
- [MySQL Packet Too Large](#)

**Bamboo MySQL Character Set**
This check verifies the correctness of the character set that is used by tables, columns, and database defaults in your MySQL database.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server.

For more information about character sets, see [MySQL Character Set Support](#).
### Bamboo MySQL Collation

The check verifies the correctness of the collation used by tables, columns, and database defaults in your MySQL database.

Incorrect collation may result in data loss, incorrect results, unwanted sorting orders, and poor performance.

For more information, see [MySQL Collation Implementation Types](#).

---

### Bamboo MySQL InnoDB Log File Size

This check verifies if the innodb_log_file_size variable in your MySQL database is appropriate.

A fail might be caused either by the maximum allowed packet size of the MySQL server being too small or when the InnoDB log file is too small (sometimes both).

For more information, see:

- [MySQLSyntaxErrorException: Row size too large](#)
- [MySQL Limits on Table Column Count and Row Size](#)

---

### Bamboo Instance Health check v6.1

Bamboo provides a set of tools that you can use to monitor the health of your instance, as well as to identify the root cause when the instance is not performing as expected.

It's recommended that you look at the status of the health check tools after you install Bamboo or when you need to troubleshoot your setup.

To access the health check tools, go to

> Overview > System > Troubleshooting and support tools. Then choose the Health Checks tab.

Health checks visibility is dependent on your instance setup. For example, MySQL health checks are visible only if you're using a MySQL database.

---

### Bamboo Instance Health check types

**Bamboo Embedded database**
Checks if the instance is connected to an HSQL database.

**Bamboo MySQL Max Allowed Packet**
Checks if the max_allowed_packet variable in your MySQL database is appropriate.

**Bamboo MySQL Character Set**
Checks if the character set used by the tables, columns and database defaults in your MySQL database is correct.

**Bamboo MySQL Collation**
Checks if the collation used by the tables, columns and database defaults in your MySQL database is correct.

**Bamboo MySQL InnoDB Log File Size**
Checks if the innodb_log_file_size variable in your MySQL database is appropriate.

---

### Bamboo Instance Health check v5.14

Bamboo provides a set of tools that you can use to monitor the health of your instance, as well as to identify the root cause when the instance is not performing as expected.

It's recommended that you look at the status of the health check tools after you install Bamboo or when you need to troubleshoot your setup.

To access the health check tools, go to

> System > Atlassian Support Tools. Then choose the Health Checks tab.

Health checks visibility is dependent on your instance setup. For example, MySQL health checks are visible only if you're using a MySQL database.
Instance Health is a functionality provided by a built-in Support Tools Plugin. For more information, see Instance Health.

**Administering Bamboo v5.14**

Bamboo is a continuous integration (CI) and deployment server. Bamboo assists software development teams by providing:

- automated building and testing of software source-code status.
- updates on successful/failed builds.
- reporting tools for statistical analysis.
- visibility into, and control over, release artifacts and environments.

This administration guide has information about managing the Bamboo server itself. Please see Using Bamboo for help with setting up CI builds and deployments.

- **Administering**
  - System settings
    - Configuring the Bamboo server.
  - Agents and capabilities
    - Setting up services, including Elastic Bamboo, to perform builds.
  - Users and permissions
    - Managing users, groups and their permissions.
  - Add-ons
    - Extending Bamboo.
  - Data and backups
    - Managing databases, data and backups.
  - Security
    - Managing security for agents and Elastic Bamboo.
Lockout recovery process

Lockout recovery process v6.6

This page describes how to recover administrator access for Bamboo 6.6 and later.

As an administrator, you may find yourself locked out of Bitbucket Server and unable to log in. This can happen for various reasons, including:

- The external user directory server is not accessible (because the network is down, or the directory is down, or the directory has been moved to another IP address).
- The admin password has been forgotten or lost.
- The Bamboo instance is not configured properly and then restarted.

To regain your access to Bamboo:

1. Add the "-Datlassian.recovery.password=temporarypassword" Java property.
   
   a. For operating system and installation specific instructions for configuring a Java property for Bamboo, please see: Configuring your system properties
   
   b. Linux Example: Edit the <Bamboo_installation_directory>/bin/setenv.sh file and add the "-Datlassian.recovery.password=temporarypassword" value to the JVM_SUPPORT_RECOMMENDED_ARGS property.

   The property value must not be blank, and should look like this when you've done that:

   ```
   # Occasionally Atlassian Support may recommend that you set some specific JVM arguments.
   # You can use this variable to do that. Simply uncomment the below line and add any required # arguments. Note however, if this environment variable has been set in the environment of the # user running this script, uncommenting the below will override that.
   #
   JVM_SUPPORT_RECOMMENDED_ARGS=-Datlassian.recovery.password=temporarypassword
   ```
Here we are using temporary password but you should use your own value.

2. Restart your Bamboo instance.
3. Log in to Bamboo using the recovery_admin username and the temporary password specified in Step 1.
4. Repair your Bamboo configuration.

In the recovery mode, Bamboo creates an additional account with administrative privileges to allow you to fix your configuration. These privileges are removed when Bamboo restarts without the recovery mode. We strongly recommend that you do not perform any additional actions while Bamboo is in recovery mode.

5. Confirm your ability to log in with your usual admin profile.
6. Shut down Bamboo and remove the atlassian.recovery.password argument.
7. Start Bamboo again.

Administering Bamboo v6.0

Bamboo is a continuous integration (CI) and deployment server. Bamboo assists software development teams by providing:

- automated building and testing of software source-code status.
- updates on successful/failed builds.
- reporting tools for statistical analysis.
- visibility into, and control over, release artifacts and environments.

This administration guide has information about managing the Bamboo server itself. Please see Using Bamboo for help with setting up CI builds and deployments.

Bamboo Specs

Configuration as code is now available in Bamboo! Learn more about this feature that lets you store build plans configuration as code.

- Why configuration as code?
- What's in the package?
  - Bamboo goodies
  - High-level language for configuration
  - Configuration in a language of your choice
  - Docs and more docs
- OK, I'm sold. Where do I start?

Why configuration as code?

Consider storing your build plan configuration as code for easier automation, change tracking, validation, and much more. You can read about the details in What is configuration as code?.

What's in the package?

✅ Bamboo goodies
  - Bamboo Specs library with an API for writing configuration as code
  - Bamboo Specs Runner Maven plugin for easier plan deployments

✅ High-level language for configuration

YAML can get the job done, but we know that enterprise users need something much more powerful. That's why we decided to use a simple Java-based plan description language:

- Enjoy highlighting, syntax checks, and code autocompletion.
- Validate when you compile and run offline tests.
• Use high-level language features like modularization or libraries.

If you're not familiar with Java, don't worry. Our onboarding process will bootstrap you directly into a working environment and we have made sure that the plan definitions will be familiar to users of other languages such as Python, C++ or C#. You can read about the details in Configuration as code in Bamboo.

✅ Configuration in a language of your choice

The Bamboo Specs library is written in Java. It means that you can write your code in any high-level JVM language that interoperates with Java, for example Groovy, Scala, or Kotlin.

✅ Docs and more docs

We're still working on our documentation, but progress is more important than perfection, so we're sharing the first versions with you.

Bamboo Specs Reference
Concepts explained with examples. We really like this one, check it out!

Bamboo Specs API reference
Our API. Documented

😊 Best practices
Because we already have some recommendations!

OK, I'm sold. Where do I start?

Easy. We've prepared a short tutorial.

Limitations

Configuration as code is available for build plans. Storing deployment plans as code isn't currently supported.

OK, I'm sold. Where do I start?

Easy. We've prepared a short tutorial.

Get started

What is configuration as code?

**Configuration as code** allows the entire configuration of Bamboo plans to be stored as source code. It moves the managing of plans from the Bamboo UI to the developer's integrated development environment (IDE). This approach brings a lot of benefits.
In a world of UI-driven configuration

Prior to Bamboo 6.0, the only way to manage projects and builds plans was via the web UI, and few REST endpoints with limited functionality. It required the user to manually create plans and add stages, jobs, and tasks to them. The user had to define source code repositories, triggers, credentials, artifacts, and much more. Although Bamboo provided shortcuts for some actions, such as cloning an existing job or plan, sharing repositories or plan branches feature, it still required a lot of effort from the Bamboo administrator to manage it.

Advantages of configuration as code

Automation and standardisation

As configuration is written as source code, you can use all best development practices to optimise it, such as: creating reusable definitions of plans, parameterisation, using loops to create lots of different entities like plans, jobs, or repositories.

It is especially crucial for large Bamboo instances with hundreds of plans. Also, in the micro-services world, it's quite common to have similar build plans.

Versioning of changes

You can store configuration code in a version control system, such as Git, to see who changed what and when in your Bamboo environment. You can use tags to mark versions that have been published to Bamboo. You can use branches to isolate changes under construction and to work in parallel streams without affecting your production Bamboo instance.

Traceability of changes

If source code is versioned and properly managed (e.g. tagged), you can track which changes have been applied to your Bamboo server. Analysing code differences (e.g. via `git diff`) is quite often more convenient and efficient that reading audit logs in Bamboo.

Smooth promotion of changes from test to production

In case you use two Bamboo servers - a production and test instance - it's a lot easier to promote changes using configuration as code. In the "UI world", you had to click through many UI pages, test that everything works and next tediously repeat the same steps on the production instance. With configuration as code you can simply deploy plans to a test instance, verify changes and then deploy to the production instance just by changing the target URL.

Keeping build environment in sync with a product

It's quite common to keep a build configuration in the same source code repository as the product being built. As your product evolves, so does the environment needed to build it. Thanks to this synchronisation, you can always set up a proper environment, no matter whether you want to build the latest commit from the master branch or a bug fix branch created a few years ago.

Coding assistance and validation

Editing build plans in an IDE (such as Eclipse or IntelliJ IDEA) allows to you use IDE features such as: code autocompletion, parameter tool tips, pop-ups with JavaDoc, code refactoring, searching for usages of a given method/object and many more. You can also quickly perform offline validation by compiling and running the code.

See next: Configuration as code in Bamboo
What is configuration as code? v6.0

Configuration as code allows the entire configuration of Bamboo plans to be stored as source code. It moves the managing of plans from the Bamboo UI to the developer's integrated development environment (IDE). This approach brings a lot of benefits.

In a world of UI-driven configuration

Prior to Bamboo 6.0, the only way to manage projects and builds plans was via the web UI and few REST endpoints with limited functionality. It required the user to manually create plans and add stages, jobs, and tasks to them. The user had to define source code repositories, triggers, credentials, artifacts, and much more. Although Bamboo provided shortcuts for some actions, such as cloning an existing job or plan, sharing repositories or plan branches feature, it still required a lot of effort from the Bamboo administrator to manage it.

Advantages of configuration as code

Automation and standardisation
As configuration is written as source code, you can use all best development practices to optimise it, such as: creating reusable definitions of plans, parameterisation, using loops to create lots of different entities like plans, jobs, or repositories. It is especially crucial for large Bamboo instances with hundreds of plans. Also, in the micro-services world, it's quite common to have similar build plans.

Versioning of changes
You can store configuration code in a version control system, such as Git, to see who changed what and when in your Bamboo environment. You can use tags to mark versions that have been published to Bamboo. You can use branches to isolate changes under construction and to work in parallel streams without affecting your production Bamboo instance.

Traceability of changes
If source code is versioned and properly managed (e.g. tagged), you can track which changes have been applied to your Bamboo server. Analysing code differences (e.g. via `git diff`) is quite often more convenient and efficient that reading audit logs in Bamboo.

You can also quickly perform offline validation by compiling and running the code.

Configuration as code in Bamboo

We've written down some details about how configuration as code works in Bamboo.

On this page

• Bamboo uses high-level language for configuration
• Bamboo allows you to write configuration in language of your choice

Related links

• Tutorial: Create a simple plan with Bamboo Java Specs
• Create a Bamboo Specs project using Maven Archetype
• Best practices

Bamboo uses high-level language for configuration

YAML can get the job done, but we know that enterprise users need something much more powerful. That's why we decided to pick Java as the default language for creating Bamboo Specs.

When using Java, you get features that aren't available in languages like YAML:

• syntax checking and highlighting while editing
• code autocompletion - IDE "knows" what is available (whereas a YAML file is just text)
• code refactoring
• code analysis - IDE helps you find usages of given method or object
• code validation by compiler - you can easily spot any spelling mistakes
• offline and online code validation by the Bamboo Specs runner
• API versioning and deprecation (via JavaDoc's '@since' and '@deprecated' tags)
• language features such as loops, modularisation, libraries etc.

Bamboo allows you to write configuration in language of your choice

The Bamboo Specs library which provides API to write configuration as code has been written in Java. Thus the most natural is to use Java to write the configuration as well and this is a language which Atlassian will officially support for Bamboo Specs.

However, if you are familiar with other JVM language and have experience how to integrate it with Java classes, you can use any language of your choice. Good examples are: Groovy, Scala or Kotlin (we performed smoke tests with Groovy and Kotlin and it worked fine).

We also provide a Spec Runner Maven plugin, which eases the deployment of plans.

See next: Tutorial: Create a simple plan with Bamboo Java Specs

Configuration as code in Bamboo v6.0

Export Bamboo plan to high level language.

- Export Bamboo plan to high level language. v6.0
- Export Bamboo plan to high level language. v6.3
- Configuration as code in Bamboo v6.3

We've written down some details about how configuration as code works in Bamboo.

On this page

- Bamboo uses high-level language for configuration
- Bamboo allows you to write configuration in language of your choice

Related links

- Tutorial: Create a simple plan with Bamboo Java Specs
- Create a Bamboo Specs project using Maven Archetype
- Best practices
• syntax checking and highlighting while editing
• code autocompletion - IDE "knows" what is available (whereas a YAML file is just text)
• code refactoring
• code analysis - IDE helps you find usages of given method or object
• code validation by compiler - you can easily spot any spelling mistakes
• API versioning and deprecation (via JavaDoc's @since and @deprecated tags)
• language features such as loops, modularisation, libraries etc.

Bamboo allows you to write configuration in language of your choice

The Bamboo Specs library which provides API to write configuration as code has been written in Java. Thus the most natural is to use Java to write the configuration as well and this is a language which Atlassian will officially support for Bamboo Specs.

However, if you are familiar with other JVM language and have experience how to integrate it with Java classes, you can use any language of your choice. Good examples are: Groovy, Scala or Kotlin (we performed smoke tests with Groovy and Kotlin and it worked fine).

We also provide a Spec Runner Maven plugin, which eases the deployment of plans.

See next: Tutorial: Create a simple plan with Bamboo Java Specs

.Bamboo Specs v6.1

Configuration as code is now available in Bamboo! Learn more about this feature that lets you store build plans configuration as code.

Why configuration as code?

Consider storing your build plan configuration as code for easier automation, change tracking, validation, and much more. You can read about the details in What is configuration as code?.

What’s in the package?

✔ Bamboo goodies
  • Bamboo Specs library with an API for writing configuration as code
  • Bamboo Specs Runner Maven plugin for easier plan deployments

✔ High-level language for configuration

YAML can get the job done, but we know that enterprise users need something much more powerful. That's why we decided to use a simple Java-based plan description language:

• Enjoy highlighting, syntax checks, and code autocompletion.
• Validate when you compile and run offline tests.
• Use high-level language features like modularization or libraries.

If you're not familiar with Java, don't worry. Our onboarding process will bootstrap you directly into a working environment and we have made sure that the plan definitions will be familiar to users of other languages such as Python, C++ or C#. You can read about the details in Configuration as code in Bamboo.

✔ Configuration in a language of your choice

The Bamboo Specs library is written in Java. It means that you can write your code in any high-level JVM language that interoperates with Java, for example Groovy, Scala, or Kotlin.
Docs and more docs

We're still working on our documentation, but progress is more important than perfection, so we're sharing the first versions with you.

Bamboo Specs Reference
Concepts explained with examples. We really like this one, check it out!

Bamboo Specs API reference
Our API. Documented 😊

Best practices
Because we already have some recommendations!

Limitations
Configuration as code is available for build plans. Storing deployment plans as code isn't currently supported.

OK, I'm sold. Where do I start?

Easy. We've prepared a short tutorial.

Quick links
- Tutorial: Create a simple plan with Bamboo Java Specs
- Bamboo Specs reference documentation
- Best practices
- What is configuration as code?
- Configuration as code in Bamboo

Enabling repository-stored Bamboo Specs

Storing Bamboo Specs in a repository allows you to keep your project configuration together with the code and automatically publish any code changes. It also gives you access to history of plan specification, and makes it easy to revert to a particular moment in time.

Before you begin

Make sure you have the following:

- native Git installed
- access to Maven central repository

To enable repository-stored Bamboo Specs:

1. Go to ➔ Linked repositories.
2. Select your repository.
   
   You must use the Bitbucket Server repository type to have Bamboo Specs executed automatically by Bamboo.

3. In the Bamboo Specs tab, enable Scan for Bamboo Specs.

Bamboo Specs from this repository will be able to modify your plans and deployments in Bamboo. Make sure that write permissions to this repository are properly set in Bitbucket Server as any commit to this repository will refresh Bamboo configuration.
4. In the **Projects** section, select which projects Bamboo Specs can access.

**All projects**
Available only for Bamboo administrators. Use this option if you want to have a repository managing multiple build plans and deployment projects in your Bamboo instance. You can also use this option if you want to be able to create new build projects and deployment projects from Bamboo Specs.

**Build projects**
You must have project administrator or Bamboo administrator permissions to add a build project. You can't add new projects here.

To add a **Build project**:

1. From the Bamboo header, click **Projects**.
2. Click your project.
3. In the top-right corner, click **Project settings**.
4. In the sidebar, click **Bamboo Specs repositories**.
5. Select your repository and click **Add**.

In case a plan downloads artifacts from another project (the Artifact Downloader task) or triggers builds of plans in another projects (the Dependencies tab on Plan configuration page), you have to grant access to these projects as well.

**Deployment projects**
You must have project administrator or Bamboo administrator permissions to add a deployment project. You can't add new projects here.

To add a **Deployment project**:

1. From the Bamboo header, click **Deploy > All Deployment Projects**.
2. Click on your project.
3. In the top-right corner, click **... > Edit project**.
4. Click **Bamboo Spec repositories**.
5. Select your repository and click **Add**.

Now, Bamboo Specs from this repository will be able to modify this deployment project and environments. Once you have added your repositories, you can see them listed in the Projects section in Linked repositories.

---

**Enabling repository-stored Bamboo Specs v6.2**

Storing Bamboo Specs in a repository allows you to keep your project configuration together with the code and automatically publish any code changes. It also gives you access to history of plan specification, and makes it easy to revert to a particular moment in time.

**Before you begin**

Make sure you have the following:
• native Git installed
• access to Maven central repository

To enable repository-stored Bamboo Specs:

1. Go to > Linked repositories.
2. Select your repository.

You must use the Bitbucket Server repository type to have Bamboo Specs executed automatically by Bamboo.

3. In the Bamboo Specs tab, enable Scan for Bamboo Specs.

Bamboo Specs from this repository will be able to modify your plans and deployments in Bamboo. Make sure that write permissions to this repository are properly set in Bitbucket Server as any commit to this repository will refresh Bamboo configuration.

4. In the Projects section, select which projects Bamboo Specs can access.

   - All projects: Available only for Bamboo administrators. Use this option if you want to have a repository managing multiple build plans and deployment projects in your Bamboo instance. You can also use this option if you want to be able to create new build projects and deployment projects from Bamboo Specs.

   - Build projects: You must have project administrator or Bamboo administrator permissions to add a build project. You can't add new projects here.

To add a Build project:

i. From the Bamboo header, click Projects.
ii. Click your project.
iii. In the top-right corner, click Project settings.
iv. In the sidebar, click Bamboo Specs repositories.
v. Select your repository and click Add.

In case a plan downloads artifacts from another project (the Artifact Downloader task) or triggers builds of plans in another projects (the Dependencies tab on Plan configuration page), you have to grant access to these projects as well.

- Deployment projects: You must have project administrator or Bamboo administrator permissions to add a deployment project. You can't add...
new projects here.

To add a Deployment project:

i. From the Bamboo header, click Deploy > All Deployment Projects.
ii. Click on your project.
iii. In the top-right corner, click [...] > Edit project.
iv. Click Bamboo Spec repositories.
v. Select your repository and click Add.

Now, Bamboo Specs from this repository will be able to modify this deployment project and environments. Once you have added your repositories, you can see them listed in the Projects section in Linked repositories.

Enabling repository-stored Bamboo Specs v6.5

Storing Bamboo Specs in a repository allows you to keep your project configuration together with the code and automatically publish any code changes. It also gives you access to history of plan specification, and makes it easy to revert to a particular moment in time.

Before you begin

Make sure you have the following:

• native Git installed
• access to Maven central repository

To enable Bitbucket Server repository-stored Bamboo Specs:

1. Go to
   > Linked repositories.
2. Select your repository.
3. In the Bamboo Specs tab, enable Scan for Bamboo Specs.

Bamboo Specs from this repository will be able to modify your plans and deployments in Bamboo. Make sure that write permissions to this repository are properly set in Bitbucket Server as any commit to this repository will refresh Bamboo configuration.

4. In the Projects section, select which projects Bamboo Specs can access.
   • All projects
     Available only for Bamboo administrators. Use this option if you want to have a repository managing multiple build plans and deployment projects in your Bamboo instance. You can also use this option if you want to be able to create new build projects and deployment projects from Bamboo Specs.
   • Build projects
     You must have project administrator or Bamboo administrator permissions to add a build project. You can't add new
projects here.

To add a Build project:

i. From the Bamboo header, click **Projects**.
ii. Click your project.
iii. In the top-right corner, click **Project settings**.
iv. In the sidebar, click **Bamboo Specs repositories**.
v. Select your repository and click **Add**.

In case a plan downloads artifacts from another project (the Artifact Downloader task) or triggers builds of plans in another projects (the Dependencies tab on Plan configuration page), you have to grant access to these projects as well.

To add a Deployment project:

i. From the Bamboo header, click **Deploy** > All Deployment Projects.
ii. Click on your project.
iii. In the top-right corner, click [...] > **Edit project**.
iv. Click **Bamboo Specs repositories**.
v. Select your repository and click **Add**.

Now, Bamboo Specs from this repository will be able to modify this deployment project and environments. Once you have added your repositories, you can see them listed in the Projects section in Linked repositories.

Deployment projects

You must have project administrator or Bamboo administrator permissions to add a deployment project. You can’t add new projects here.

Additional step for other repositories

Starting from version 6.5, you will be able to use Bamboo Specs Java and YAML with the following repositories:

- Bitbucket Cloud
- Git
- GitHub
- Subversion

Webhooks allow your repositories other than Bitbucket Server to communicate with Bamboo. Once you set up a webhook for a repository, it sends the HTTP request to Bamboo with every new commit. This HTTP request, in turn, triggers Bamboo Specs scan repository to see if there are any changes to Specs. If Bamboo detects any changes in a repository, it automatically updates necessary plans and deployments. Learn more about setting up webhooks.

**Bamboo Specs v6.2**

Configuration as code is now available in Bamboo! Learn more about this feature that lets you store build plans configuration as code.

- Why configuration as code?
- What’s in the package?

Quick links

- Tutorial: Create a simple plan with Bamboo Java Specs
- Bamboo Specs reference documentation
- Best practices
- What is configuration as code?
- Configuration as code in Bamboo

OK, I'm sold. Where do I start?

Easy. We've prepared a short tutorial.

Get started

Bamboo Java Specs

Create a Bamboo Specs project using Maven Archetype

You can create Bamboo Specs projects using our Maven Archetype.

On this page

- Basic usage
- Additional options
- Importing created project into IDE
- Troubleshooting

Related links

- Tutorial: Create a simple plan with Bamboo Java Specs
- Bamboo Specs reference documentation
- Bamboo Specs API reference
Basic usage

You can quickly create a basic Bamboo Specs project using the following command:

```
mvn archetype:generate -DarchetypeGroupId=com.atlassian.bamboo
- DarchetypeArtifactId=bamboo-specs-archetype \
- DarchetypeVersion=6.0.0
```

This command runs in the interactive mode. You will be asked to provide the following parameters for the project:

- groupId
- artifactId
- a version
- a package prefix

The command creates a directory that has the name specified in the artifactId parameter.

You can also run the command in the batch mode and provide all necessary parameters:

```
mvn archetype:generate -B \
- DarchetypeGroupId=com.atlassian.bamboo
- DarchetypeArtifactId=bamboo-specs-archetype \
- DarchetypeVersion=6.0.0 \
- DgroupId=com.my.company -DartifactId=my-bamboo-casc \
- Dversion=1.0.0 -Dpackage=com.my.company
```

Additional options

- `-Dtemplate=minimal` - creates a minimal template (with no repositories, stages, or artifacts)

Importing created project into IDE

You can easily import the project into IDE, such as Eclipse or IntelliJ IDEA.

**How to import into Eclipse** ...

1. Run Eclipse.
2. From the main menu, select File > Import...
3. In the Import dialog, click Maven > Existing Maven Projects and click Next.
4. Click Browse, select your folder, and click Open.
5. Click Finish.
   
   Eclipse creates a new project and downloads necessary dependencies.

**How to import into IntelliJ IDEA** ...

1. Run IntelliJ IDEA.
2. From the main menu, click File > Open and select the pom.xml file.
3. Click Open as Project.
   
   IntelliJ IDEA creates a new project and downloads necessary dependencies.

Troubleshooting

**Unable to add module**
Create a Bamboo Specs project using Maven Archetype v6.0

You can create Bamboo Specs projects using our Maven Archetype.

On this page

- Basic usage

-DgroupId=com.my.company -DartifactId=my-bamboo-casc \   
-Dversion=1.0.0 -Dpackage=com.my.company

**Additional options**

- `-Dtemplate=minimal` - creates a minimal template (with no repositories, stages, or artifacts)

**Importing created project into IDE**

You can easily import the project into IDE, such as Eclipse or IntelliJ IDEA.

**How to import into Eclipse** ...

1. Run Eclipse.
2. From the main menu, select **File > Import**...
3. In the Import dialog, click **Maven > Existing Maven Projects** and click **Next**.
4. Click **Browse**, select your folder, and click **Open**.
5. Click **Finish**.
   
   Eclipse creates a new project and downloads necessary dependencies.

**How to import into IntelliJ IDEA** ...

1. Run IntelliJ IDEA.
2. From the main menu, click **File > Open** and select the **pom.xml** file.
3. Click **Open as Project**.
   
   IntelliJ IDEA creates a new project and downloads necessary dependencies.

**Troubleshooting**

**Unable to add module**

```
[ERROR] Failed to execute goal
org.apache.maven.plugins:maven-archetype-plugin:3.0.0:generate
  (default-cli) on project p4:
org.apache.maven archetype.exception.InvalidPackaging:
  Unable to add module to the current project as it is not of
  packaging type 'pom' -> [Help 1]
```

The archetype found pom.xml file in the current directory and failed to add the module to it.

Run the archetype from a directory which does not contain the pom.xml file.

---

**Creating deployment projects in Bamboo Specs**

Bamboo Specs can be used to create and update deployment projects.

Creating deployment projects in Bamboo Specs is similar to that of updating a plan. The main difference is the class you need to define in your Bamboo Specs code:

```
```
private Deployment createDeployment() {
    return new Deployment(new PlanIdentifier("PROJECTKEY", "PLANKEY"),
                             "Deployment project name")
            .releaseNaming(new ReleaseNaming("release-1")
                            .autoIncrement(true))
            .environments(new Environment("Test environment")
                            .tasks(new ScriptTask().inlineBody("echo Hello world!"))));
}

Once you defined this class, instruct Bamboo Specs to publish your deployment to deployment server, just like you do with plans:

Deployment myDeployment = createDeployment();
bambooServer.publish(myDeployment);

Creating deployment projects in Bamboo Specs v6.1

Bamboo Specs can be used to create and update deployment projects.

Creating deployment projects in Bamboo Specs is similar to that of updating a plan. The main difference is the class you need to define in your Bamboo Specs code:

private Deployment createDeployment() {
    return new Deployment(new PlanIdentifier("PROJECTKEY", "PLANKEY"),
                             "Deployment project name")
            .releaseNaming(new ReleaseNaming("release-1")
                            .autoIncrement(true))
            .environments(new Environment("Test environment")
                            .tasks(new ScriptTask().inlineBody("echo Hello world!"))));
}

Once you defined this class, instruct Bamboo Specs to publish your deployment to deployment server, just like you do with plans:

Deployment myDeployment = createDeployment();
bambooServer.publish(myDeployment);

Creating deployment projects in Bamboo Specs v6.2

Bamboo Specs can be used to create and update deployment projects.

Creating deployment projects in Bamboo Specs is similar to that of updating a plan. The main difference is the class you need to define in your Bamboo Specs code:
private Deployment createDeployment() {
    return new Deployment(new PlanIdentifier("PROJECTKEY", "PLANKEY"),
                           "Deployment project name")
      .releaseNaming(new ReleaseNaming("release-1")
                     .autoIncrement(true))
      .environments(new Environment("Test environment")
                        .tasks(new ScriptTask().inlineBody("echo Hello world!")));
}

Once you defined this class, instruct Bamboo Specs to publish your deployment to deployment server, just like you do with plans:

   Deployment myDeployment = createDeployment();
   bambooServer.publish(myDeployment);

Exporting existing plans to Bamboo Specs

To ease migration of your Bamboo plans to configuration as code, we have prepared the export feature. In order to export existing plan to Bamboo Specs source code:

1. If you don’t have Bamboo Specs project, create one.
2. Go to your plan and select Actions > Configure plan.
3. On the plan configuration page, select Actions > View plan as Bamboo Specs.
4. Copy generated Java code to your code editor by putting it in the PlanSpec#createPlan method for instance.

The code is ready to run, with few exceptions:

- sensitive data is not exported - you will see "/* PUT YOUR SENSITIVE INFORMATION HERE*/" code comment to fill up the data
- manually created branches are not exported - you can add them manually in the UI

We advise you to cross-check the generated code with Bamboo Specs reference manual and to compare original and generated plan.

You will find equivalent classes for the vast majority of Bamboo concepts in the generated code, such as: plans, stages, jobs, tasks of different kinds, permissions, deployments. The export feature also handles tasks not known to Bamboo (e.g. third party plugins or a plugin written by you) via a generic AnyTask class.

You may want to refactor the code generated, for instance: split code into smaller methods, extract common parts or merge code from several Bamboo plans into one Bamboo Spec project.

### Exporting existing plans to Bamboo Specs v6.0

This feature is in the beta phase

Because of that, the generated code might not be complete or work properly.

The generated code may not contain all required tasks:

- you may see a "Support for <task name> coming soon" inline comment for some of them,
- you may see a generic AnyTask class used for some of them.

The generated code may also miss required parameters or features (e.g. plan permissions and manually created branches are not supported at the moment) or have compilation errors. It means that a plan created by Bamboo Specs code may differ from the original plan.

Cross-check the generated code with Bamboo Specs reference manual and make sure to compare original and generated plan.

To ease migration of your Bamboo plans to configuration as code, we have prepared the export feature. In order to export existing plan to Bamboo Specs source code:

1. If you don’t have Bamboo Specs project, create one.
2. Go to your plan and select Actions > Configure plan.
3. On the plan configuration page, select Actions > View plan as Bamboo Specs.
4. Copy generated Java code to your code editor by putting it in the PlanSpec#createPlan method for instance.
You may want to refactor the code generated, for instance: split code into smaller methods, extract common parts or merge code from several Bamboo plans into one Bamboo Spec project.

### Exporting existing plans to Bamboo Specs v6.2

To ease migration of your Bamboo plans to configuration as code, we have prepared the export feature. In order to export existing plan to Bamboo Specs source code:

1. If you don't have Bamboo Specs project, **create one**.
2. Go to your plan and select **Actions > Configure plan**.
3. On the plan configuration page, select **Actions > View plan as Bamboo Specs**.
4. Copy generated Java code to your code editor by putting it in the `PlanSpec#createPlan` method for instance.

The code is ready to run, with few exceptions:

- sensitive data is not exported - you will see "/* PUT YOUR SENSITIVE INFORMATION HERE*/" code comment to fill up the data
- manually created branches are not exported - you can add them manually in the UI

We advise you to cross-check the generated code with [Bamboo Specs reference manual](https://confluence.atlassian.com/display/起了一个rea) and to compare original and generated plan.

You will find equivalent classes for the vast majority of Bamboo concepts in the generated code, such as: plans, stages, jobs, tasks of different kinds, permissions, deployments. The export feature also handles tasks not known to Bamboo (e.g. third party plugins or a plugin written by you) via a generic *AnyTask* class.

You may want to refactor the code generated, for instance: split code into smaller methods, extract common parts or merge code from several Bamboo plans into one Bamboo Spec project.

### Bamboo Java Specs v6.3

We've written down some details about how configuration as a code in Java works in Bamboo.

Bamboo uses high-level language for configuration

YAML can get the job done when you want to define your plan quickly but we know that enterprise users sometimes need something much more powerful. That's why we decided to pick Java as the default language for creating Bamboo Specs.

When using Java, you get the following features:

- syntax checking and highlighting while editing
- code autocompletion - IDE "knows" what is available (whereas a YAML file is just text)
- code refactoring
- code analysis - IDE helps you find usages of given method or object
- code validation by the compiler - you can easily spot any spelling mistakes
- offline and online code validation by the *Bamboo Specs* runner
- API versioning and deprecation (via JavaDoc's `@since` and `@deprecated` tags)
- language features such as loops, modularisation, libraries etc.

Bamboo allows you to write configuration in language of your choice

The [Bamboo Specs library](https://confluence.atlassian.com/display/起了一个rea) which provides API to write configuration as code has been written in Java. Thus the most natural is to use Java to write the configuration as well and this is a language which Atlassian will officially support for Bamboo Specs.

However, if you are familiar with other JVM language and have experience how to integrate it with Java classes, you can use any language of your choice. Good examples are: Groovy, Scala or Kotlin (we performed smoke tests with Groovy and Kotlin and it worked fine).

We also provide a [Spec Runner](https://confluence.atlassian.com/display/起了一个rea) Maven plugin, which eases the deployment of plans.

**Best practices**

There's a couple of things that we find important.

---

**On this page**

- Keep your project in version control system
- Keep information from which URL a given plan was created
- Keep in mind that your plan configuration is source code as any other

**Related links**

- Tutorial: Create a simple plan with Bamboo Java Specs
- Create a Bamboo Specs project using Maven

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Keep your project in version control system

Keeping your code in VCS, such as Git or Mercurial will give you a lot of benefits, such as:

- traceability - you can track who, when and why changed your build environment
- comparison - you can easily compare two different configurations to analyse what changed, which helps when troubleshooting
- separation of work - you can use branches to prepare new versions of your environment
- remaining in sync with the product.

Keep information from which URL a given plan was created

With hundreds of plans and separate configuration projects it’s very valuable to know which plan is being managed by CASC and which via UI, and which repository manages a given plan in Bamboo.

To stay on top of things, use plan description field for this purpose, e.g.:

“This plan is being managed via configuration-as-code. Modify `<vcs url>` project to update the plan.”

Keep in mind that your plan configuration is source code as any other

Apply all best development practices when maintaining it. Avoid copy-and-paste, extract common methods or components, use parameterization, modularization.

Go back: Bamboo Specs

Best practices v6.0

There’s a couple of things that we find important.
via UI, and which repository manages a given plan in Bamboo.

To stay on top of things, use plan description field for this purpose, e.g.:

"This plan is being managed via configuration-as-code. Modify <vcs url> project to update the plan."

Keep in mind that your plan configuration is source code as any other

Go back: Bamboo Specs

Tutorial: Create a simple plan with Bamboo Specs

This guide will help you understand how to create plans with Bamboo Specs. You'll create a simple project and execute it to create a plan in Bamboo.

Before you begin

Make sure you have the following installed:

- JDK 8 or higher
- Maven 3.2 or higher
- Eclipse or IntelliJ IDEA IDE

Note: You may use a different IDE, but tutorial provides examples for the two above

- Bamboo 6.0 or higher

Step 1: Create a project base with Maven

To create a base of the project, execute the following Maven archetype:
Step 2: Import the project into IDE

You can now import the project into your integrated development environment (IDE).

**How to import into Eclipse**

1. Run Eclipse.
2. In the main menu, go to File > Import.
3. In the Import dialog, select Maven > Existing Maven Projects.
4. Click Next.
5. Click Browse.
6. Select the `bamboo-specs-tutorial` directory and click Open.
7. Click Finish.

Eclipse will create a new project and download necessary dependencies (it may take a while).

**How to import into IntelliJ IDEA**

1. Run IntelliJ IDEA.
2. In the main menu, go to File > Open.
3. Select the `pom.xml` file.
4. Click Open as project.

IntelliJ IDEA will create a new project and download necessary dependencies, which might take a while.

If you want to see how PlanSpec.java files is structured, go to src/main/java/tutorial/PlanSpec.java. You file should have the following structure:

<table>
<thead>
<tr>
<th>PlanSpec</th>
<th>The name of the class. You can use any class name.</th>
</tr>
</thead>
<tbody>
<tr>
<td>BambooSpec</td>
<td>The file is annotated. The annotation is used by the <code>spec-runner</code> Maven plugin to find classes containing Bamboo plans.</td>
</tr>
<tr>
<td>main</td>
<td>With the <code>main</code> method you can run the project as any other Java application.</td>
</tr>
</tbody>
</table>
BambooServer

The project uses the BambooServer class to publish plans with password authentication. The username and password are read from the .credentials file which is located in the current working directory.

### Step 3: Define a job with a script task

1. In the `createPlan` method put a cursor after the `description` method call:

   ```java
   private Plan createPlan() {
       return new Plan(
           project(),
           "Plan Name", "PLANKEY")
           .description("Plan created from (enter repository
url of your plan"));
   }
   ```

2. Type `.` and let your IDE show you available options:

   Pick the `stages` method and add the `new Stage("Stage 1")` constructor call inside the method's argument (you need to add the import statement for Stage class).

3. Add a job to the stage using the `jobs` method and `new Job()` constructor (add the import statement too). Name the job `Build & run` and use `RUN` for a key:

   ```java
   private Plan createPlan() {
       return new Plan(
           project(),
           "Plan Name", "PLANKEY")
           .description("Plan created from (enter repository
url of your plan")
           .stages(
               new Stage("Stage 1")
               .jobs(new Job("Build & run",
               "RUN")));
   }
   ```

5. Let's add a task to the job. Type `.tasks()` and declare a new `ScriptTask()` inside as shown below (add the import statement too). Call `.inlineBody` on the `ScriptTask()`.
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
        .description("Plan created from (enter repository url of your plan)")
        .stages(
            new Stage("Stage 1")
            .jobs(new Job("Build & run", "RUN")
            .tasks(
                new ScriptTask().inlineBody("echo Hello world!"));
    }

You can always open a JavaDoc dialog to learn more about given method or class:

- How to show JavaDoc in Eclipse
  To download JavaDocs, hold the Ctrl/Cmd key, place the mouse cursor over a method or class name, and click open declaration.
  It opens a source editor with a decompiled class file. Eclipse immediately starts downloading sources and JavaDoc JARs in the background and updates editor as soon as it completes.
  To display JavaDocs place the mouse cursor over a class or method name.

- How to show JavaDoc in IntelliJ IDEA
  To download JavaDocs hold the Ctrl/Cmd key and click the method or class name.
  It opens a source editor with the decompiled class file. Click the Download sources link. IDEA will download sources and JavaDoc JARs.
  To display JavaDocs place the cursor over a method or class name and press Ctrl+J to open a quick documentation pop-up.

Step 4: Validate Bamboo Specs offline

You can perform offline validation before deploying a plan to Bamboo. Let's try it out by running a unit test.

- How to run from Maven
  mvn test

- How to run from Eclipse
  1. Right-click src/test/java/tutorial/PlanSpecTest.java in the Package Explorer view.
  2. Select Run as > JUnit test.

- How to run from IntelliJ IDEA
  1. Right-click the src/test/java/tutorial/PlanSpecTest class in the Project view.
  2. Click Run 'PlanSpecTest' .

Test fails with the following stack trace:
com.atlassian.bamboo.specs.api.exceptions.PropertiesValidationException:
Plan or job / Name: can not contain any of those characters: [", &,
', <, >, \] but it is 'Build & run'

at com.atlassian.bamboo.specs.api.validators.common.ImporterUtils.checkNoErrors(ImporterUtils.java:44)
...
at tutorial.PlanSpec.createPlan(PlanSpec.java:42)
at tutorial.PlanSpecTest.checkYourPlanOffline(PlanSpecTest.java:12)

where:

<table>
<thead>
<tr>
<th>Plan or job / Name</th>
<th>A path to an invalid element</th>
</tr>
</thead>
<tbody>
<tr>
<td>can not contain ...</td>
<td>Expected and actual value</td>
</tr>
<tr>
<td>but it is ...</td>
<td></td>
</tr>
<tr>
<td>PlanSpec.java:42</td>
<td>The source line containing the error</td>
</tr>
</tbody>
</table>

As you can see, the validation fails because the name of the job contains an invalid & character. Let’s remove it. Your code should look like this now:

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
            .description("Plan created from (enter repository url of your plan)")
            .stages(
                new Stage("Stage 1")
                    .jobs(new Job("Run", "RUN")
                        .tasks(
                            new ScriptTask().inlineBody("echo Hello world!")
                        )));
}
```

Run the test again to make sure that it passes this time.

Step 5: Publish Bamboo Specs to the Bamboo server

- Make sure that your Bamboo instance is up and running
- If you’re not running Bamboo on your local machine (http://localhost:8085), change the `bambooUrl` variable in the `main` method.
- We’re assuming that you have an administrator account with username `admin` and password `admin`. If you want to use other credentials, you need to update the `.credentials` file located in the root directory of the project.

When you’re sending a plan, Bamboo validates it.

How to run from Maven

The `pom.xml` contains the `publish-specs` profile which executes the `spec-runner` Maven plugin. So just type:
mvn -Ppublish-specs

How to run from Eclipse
1. Right-click on the PlanSpec class in the Package Explorer view.
2. Click Run as > Java application.

How to run from IntelliJ IDEA
1. Right-click the PlanSpec class in the Project view.
2. Click Run 'PlanSpec.main()'.

The console output looks like this:

```
Publishing plan PLANKEY
Result OK: http://localhost:8085/browse/PRJ-PLANKEY
```

For more verbose logging, add -Dbamboo.specs.log.level=DEBUG program argument when running Bamboo Specs.

Step 6: Check the results
1. Go to your Bamboo instance.
2. Open the plan that you created.
3. Go to Actions > Configure plan.
4. Check whether the stage contains a job with the Hello world Script Task.
5. Click Run > Run plan to execute the build.
6. Find the "Hello World!" message in the logs.

Having configuration written as code using Bamboo Specs you can very easily manage all your build plans in Bamboo.

This is very convenient method of managing large Bamboo instances with huge number of plans, publishing plans on Bamboo test instances before promoting changes to production, and tracking configuration changes in version control system.

Read What is Configuration as Code? to learn more about the benefits of using Bamboo Specs.

Next steps
Here are some resources that can help you with writing your own Bamboo Specs:

- Create a Bamboo Specs project using Maven Archetype
- Exporting existing plans to Bamboo Specs
- Creating deployment projects in Bamboo Specs
- Bamboo Specs reference
- Bamboo Specs API reference

Tutorial: Create a simple plan with Bamboo Java Specs v6.3

This guide will help you understand how to create plans with Bamboo Java Specs. You’ll create a simple project and execute it to create a plan in Bamboo.
Before you begin

Make sure you have the following installed:

- JDK 8 or higher
- Maven 3.2 or higher
- Eclipse or IntelliJ IDEA IDE

Note: You may use a different IDE, but tutorial provides examples for the two above

- Bamboo 6.0 or higher

Step 1: Create a project base with Maven

To create a base of the project, execute the following Maven archetype:

```bash
mvn archetype:generate -B \
   -DarchetypeGroupId=com.atlassian.bamboo \
   -DarchetypeArtifactId=bamboo-specs-archetype \
   -DarchetypeVersion=6.2.1 \
   -DgroupId=com.atlassian.bamboo -DartifactId=bamboo-specs \
   -Dversion=1.0.0-SNAPSHOT \
   -Dpackage=tutorial -Dtemplate=minimal
```

where:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>archetypeGroupId</td>
<td>Bamboo archetype identifiers</td>
</tr>
<tr>
<td>archetypeArtifactId</td>
<td>Bamboo archetype identifiers</td>
</tr>
<tr>
<td>archetypeVersion</td>
<td>Bamboo archetype identifiers</td>
</tr>
<tr>
<td>groupId</td>
<td>Project identifiers</td>
</tr>
<tr>
<td>artifactId</td>
<td>Project identifiers</td>
</tr>
<tr>
<td>version</td>
<td>Project identifiers</td>
</tr>
<tr>
<td>package</td>
<td>Prefix of the Java package that you want to use for the project</td>
</tr>
<tr>
<td>template</td>
<td>Type of code in which the project is generated. For the purpose of this tutorial we're using minimal.</td>
</tr>
</tbody>
</table>

The project is created in the `bamboo-specs-tutorial` directory:

```bash
cd bamboo-specs
```

Step 2: Import the project into IDE

You can now import the project into your integrated development environment (IDE).

How to import into Eclipse

1. Run Eclipse.
2. In the main menu, go to File > Import.
3. In the **Import** dialog, select **Maven > Existing Maven Projects**.
4. Click **Next**.
5. Click **Browse**.
6. Select the `bamboo-specs-tutorial` directory and click **Open**.
7. Click **Finish**.

Eclipse will create a new project and download necessary dependencies (it may take a while).

**How to import into IntelliJ IDEA**

1. Run IntelliJ IDEA.
2. In the main menu, go to **File > Open**.
3. Select the `pom.xml` file.
4. Click **Open as project**.

IntelliJ IDEA will create a new project and download necessary dependencies, which might take a while.

If you want to see how PlanSpec.java files is structured, go to `src/main/java/tutorial/PlanSpec.java`. Your file should have the following structure:

<table>
<thead>
<tr>
<th>PlanSpec</th>
<th>The name of the class. You can use any class name.</th>
</tr>
</thead>
<tbody>
<tr>
<td>BambooSpec</td>
<td>The file is annotated. The annotation is used by the <code>spec-runner</code> Maven plugin to find classes containing Bamboo plans.</td>
</tr>
<tr>
<td>main</td>
<td>With the <code>main</code> method you can run the project as any other Java application.</td>
</tr>
<tr>
<td>BambooServer</td>
<td>The project uses the <code>BambooServer</code> class to publish plans with password authentication. The username and password are read from the <code>.credentials</code> file which is located in the current working directory.</td>
</tr>
</tbody>
</table>

**Step 3: Define a job with a script task**

1. In the `createPlan` method, put a cursor after the `description` method call:

   ```java
   private Plan createPlan() {
       return new Plan(
           project(),
           "Plan Name", "PLANKEY")
           .description("Plan created from (enter repository url of your plan)")
           ;
   }
   ```

2. Type `**.` and let your IDE show you available options:
3. Pick the `stages` method and add the `new Stage("Stage 1")` constructor call inside the method's argument (you need to add the import statement for Stage class).

4. Add a job to the stage using the `jobs` method and `new Job()` constructor (add the import statement too). Name the job `Build & run` and use `RUN` for a key:

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
    .description("Plan created from (enter repository url of your plan")
    .stages(
        new Stage("Stage 1")
        .jobs(new Job("Build & run", "RUN")))
    };
```

5. Let's add a task to the job. Type `.tasks()` and declare a new `ScriptTask()` inside as shown below (add the import statement too). Call `.inlineBody` on the `ScriptTask()`.

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
    .description("Plan created from (enter repository url of your plan")
    .stages(
        new Stage("Stage 1")
        .jobs(new Job("Build & run", "RUN")
        .tasks(
            new ScriptTask().inlineBody("echo Hello world!")))
    };
```

---

You can always open a JavaDoc dialog to learn more about given method or class:

- **How to show JavaDoc in Eclipse**
  To download JavaDocs, hold the `Ctrl/Cmd` key, place the mouse cursor over a method or class name, and click `open declaration`.
  It opens a source editor with a decompiled class file. Eclipse immediately starts downloading sources and JavaDoc JARs in the background and updates editor as soon as it completes.
  To display JavaDocs place the mouse cursor over a class or method name.

- **How to show JavaDoc in IntelliJ IDEA**
  To download JavaDocs hold the `Ctrl/Cmd` key and click the method or class name.
  It opens a source editor with the decompiled class file. Click the `Download sources` link. IDEA will download sources and JavaDoc JARs.
  To display JavaDocs place the cursor over a method or class name and press `Ctrl+J` to open a quick documentation pop-up.

---

**Step 4: Validate Bamboo Specs offline**
You can perform offline validation before deploying a plan to Bamboo. Let's try it out by running a unit test.

**How to run from Maven**
```
mvn test
```

**How to run from Eclipse**
1. Right-click `src/test/java/tutorial/PlanSpecTest.java` in the Package Explorer view.
2. Select Run as > JUnit test.

**How to run from IntelliJ IDEA**
1. Right-click the `src/test/java/tutorial/PlanSpecTest` class in the Project view.
2. Click Run 'PlanSpecTest'.

Test fails with the following stack trace:

```java
com.atlassian.bamboo.specs.api.exceptions.PropertiesValidationException: Plan or job / Name: can not contain any of those characters: [", &, ',', <, >, \] but it is 'Build & run'
  at com.atlassian.bamboo.specs.api.validators.common.ImporterUtils.checkNoErrors(ImporterUtils.java:44)
  ... at tutorial.PlanSpec.createPlan(PlanSpec.java:42)
  at tutorial.PlanSpecTest.checkYourPlanOffline(PlanSpecTest.java:12)
```

<table>
<thead>
<tr>
<th>Plan or job / Name</th>
<th>A path to an invalid element</th>
</tr>
</thead>
<tbody>
<tr>
<td>can not contain ...</td>
<td>Expected and actual value</td>
</tr>
<tr>
<td>but it is ...</td>
<td></td>
</tr>
</tbody>
</table>

As you can see, the validation fails because the name of the job contains an invalid `&` character. Let's remove it. Your code should look like this now:

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
            .description("Plan created from (enter repository url of your plan)")
            .stages(
                new Stage("Stage 1")
                    .jobs(new Job("Run", "RUN")
                        .tasks(
                            new ScriptTask().inlineBody("echo Hello world!")))
            );
}
```
Run the test again to make sure that it passes this time.

**Step 5: Publish Bamboo Specs to the Bamboo server**

- Make sure that your Bamboo instance is up and running
- If you're not running Bamboo on your local machine (http://localhost:8085), change the bambooUrl variable in the main method.
- We're assuming that you have an administrator account with username admin and password admin. If you want to use other credentials, you need to update the .credentials file located in the root directory of the project.

When you're sending a plan, Bamboo validates it.

**How to run from Maven**

The pom.xml contains the 'publish-specs' profile which executes the spec-runner Maven plugin. So just type:

```
mvn -Ppublish-specs
```

**How to run from Eclipse**

1. Right-click on the PlanSpec class in the Package Explorer view.
2. Click Run as > Java application.

**How to run from IntelliJ IDEA**

1. Right-click the PlanSpec class in the Project view.
2. Click Run 'PlanSpec.main()'.

The console output looks like this:

```
Publishing plan PLANKEY
Result OK: http://localhost:8085/browse/PRJ-PLANKEY
```

For more verbose logging, add -Dbamboo.specs.log.level=DEBUG program argument when running Bamboo Specs.

**Step 6: Check the results**

1. Go to your Bamboo instance.
2. Open the plan that you created.
3. Go to Actions > Configure plan.
4. Check whether the stage contains a job with the Hello world Script Task.
5. Click Run > Run plan to execute the build.
6. Find the "Hello World!" message in the logs.

Having configuration written as code using Bamboo Specs you can very easily manage all your build plans in Bamboo.

This is very convenient method of managing large Bamboo instances with huge number of plans, publishing plans on Bamboo test instances before promoting changes to production, and tracking configuration changes in version control system.

Read What is Configuration as Code? to learn more about the benefits of using Bamboo Specs.

<td></td>
</tr>
<tr>
<td>groupId</td>
<td>Project identifiers</td>
</tr>
<tr>
<td>artifactId</td>
<td></td>
</tr>
<tr>
<td>version</td>
<td></td>
</tr>
<tr>
<td>package</td>
<td>Prefix of the Java package that you want to use for the project</td>
</tr>
<tr>
<td>template</td>
<td>Type of code in which the project is generated. For the purpose of this tutorial we're using minimal.</td>
</tr>
</tbody>
</table>

Created by Atlassian in 2018. Licensed under a [Creative Commons Attribution 2.5 Australia License](https://creativecommons.org/licenses/by/2.5/au/).
The project is created in the `bamboo-specs-tutorial` directory:

```
cd bamboo-specs-tutorial
```

**Step 2: Import the project into IDE**

You can now import the project into your integrated development environment (IDE).

- **How to import into Eclipse**
  1. Run Eclipse.
  2. In the main menu, go to File > Import.
  3. In the Import dialog, select Maven > Existing Maven Projects.
  4. Click Next.
  5. Click Browse.
  6. Select the `bamboo-specs-tutorial` directory and click Open.
  7. Click Finish.

  Eclipse will create a new project and download necessary dependencies (it may take a while).

- **How to import into IntelliJ IDEA**
  1. Run IntelliJ IDEA.
  2. In the main menu, go to File > Open.
  3. Select the `pom.xml` file.
  4. Click Open as project.

  IntelliJ IDEA will create a new project and download necessary dependencies, which might take a while.

If you want to see how PlanSpec.java files is structured, go to src/main/java/tutorial/PlanSpec.java. You file should have the following structure:

<table>
<thead>
<tr>
<th>PlanSpec</th>
<th>The name of the class. You can use any class name.</th>
</tr>
</thead>
<tbody>
<tr>
<td>BambooSpec</td>
<td>The file is annotated. The annotation is used by the spec-runner Maven plugin to find classes containing Bamboo plans.</td>
</tr>
<tr>
<td>main</td>
<td>With the main method you can run the project as any other Java application.</td>
</tr>
<tr>
<td>BambooServer</td>
<td>The project uses the BambooServer class to publish plans with password authentication. The username and password are read from the .credentials file which is located in the current working directory.</td>
</tr>
</tbody>
</table>

**Step 3: Define a job with a script task**

1. In the `createPlan` method put a cursor after the `description` method call:

   ```java
   private Plan createPlan() {
       return new Plan(
           project(),
           "Plan Name", "PLANKEY")
               .description("Plan created from (enter repository url of your plan)");
   }
   ```

2. Type `*.` and let your IDE show you available options:
3. Pick the `stages` method and add the `new Stage("Stage 1")` constructor call inside the method's argument (you need to add the import statement for `Stage` class).

4. Add a job to the stage using the `jobs` method and `new Job()` constructor (add the import statement too). Name the job `Build & run` and use `RUN` for a key:

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY"
    ).description("Plan created from (enter repository url of your plan)"
    ).stages(
        new Stage("Stage 1"
    ).jobs(new Job("Build & run", "RUN"));
}
```

5. Let's add a task to the job. Type `.tasks()` and declare a new `ScriptTask()` inside as shown below (add the import statement too). Call `.inlineBody` on the `ScriptTask()`.

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY"
    ).description("Plan created from (enter repository url of your plan)"
    ).stages(
        new Stage("Stage 1"
    ).jobs(new Job("Build & run", "RUN")
        .tasks(
            new ScriptTask().inlineBody("echo Hello world!")
        ));
}
```
Step 4: Validate Bamboo Specs offline

You can perform offline validation before deploying a plan to Bamboo. Let's try it out by running a unit test.

How to run from Maven

mvn test

How to run from Eclipse

1. Right-click src/test/java/tutorial/PlanSpecTest.java in the Package Explorer view.
2. Select Run as > JUnit test.

How to run from IntelliJ IDEA

1. Right-click the src/test/java/tutorial/PlanSpecTest class in the Project view.
2. Click Run 'PlanSpecTest'.

Test fails with the following stack trace:

```
com.atlassian.bamboo.specs.api.exceptions.PropertiesValidationException:
Plan or job / Name: can not contain any of those characters: [", &, ", <, >, \] but it is 'Build & run'
at com.atlassian.bamboo.specs.api.validators.common.ImporterUtils.checkNoErrors(ImporterUtils.java:44)
...at tutorial.PlanSpec.createPlan(PlanSpec.java:42)
at tutorial.PlanSpecTest.checkYourPlanOffline(PlanSpecTest.java:12)
```

where:

<table>
<thead>
<tr>
<th>Plan or job / Name</th>
<th>A path to an invalid element</th>
</tr>
</thead>
<tbody>
<tr>
<td>can not contain ...</td>
<td>Expected and actual value</td>
</tr>
<tr>
<td>but it is ...</td>
<td></td>
</tr>
<tr>
<td>PlanSpec.java:42</td>
<td>The source line containing the error</td>
</tr>
</tbody>
</table>
As you can see, the validation fails because the name of the job contains an invalid & character. Let’s remove it. Your code should look like this now:

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
            .description("Plan created from (enter repository url of your plan")
            .stages(
                new Stage("Stage 1")
                    .jobs(new Job("Run", "RUN")
                        .tasks(
                            new ScriptTask().inlineBody("echo Hello world!"))));
}
```

Run the test again to make sure that it passes this time.

**Step 5: Publish Bamboo Specs to the Bamboo server**

- Make sure that your Bamboo instance is up and running
- If you’re not running Bamboo on your local machine (http://localhost:8085), change the bambooUrl variable in the main method.
- We’re assuming that you have an administrator account with username admin and password admin. If you want to use other credentials, you need to update the .credentials file located in the root directory of the project.

When you’re sending a plan, Bamboo validates it.

- **How to run from Maven**
  The pom.xml contains the ‘publish’ profile which executes the spec-runner Maven plugin. So just type:
  ```
  mvn -Ppublish-specs
  ```

- **How to run from Eclipse**
  1. Right-click on the PlanSpec class in the Package Explorer view.
  2. Click Run as > Java application.

- **How to run from IntelliJ IDEA**
  1. Right-click the PlanSpec class in the Project view.
  2. Click Run 'PlanSpec.main()'.

The console output looks like this:

```text
Publishing plan PLANKEY
Result OK: http://localhost:8085/browse/PRJ-PLANKEY
```

**Step 6: Check the results**

1. Go to your Bamboo instance.
2. Open the plan that you created.
3. Go to Actions > Configure plan.
4. Check whether the stage contains a job with the Hello world Script Task.
5. Click Run > Run plan to execute the build.
6. Find the "Hello World!" message in the logs.

Having configuration written as code using Bamboo Specs you can very easily manage all your build plans in Bamboo.

This is very convenient method of managing large Bamboo instances with huge number of plans, publishing plans on Bamboo test instances before promoting changes to production, and tracking configuration changes in version control system.

Read What is Configuration as Code? to learn more about the benefits of using Bamboo Specs.

Next steps

Here are some resources that can help you with writing your own Bamboo Specs:

- Create a Bamboo Specs project using Maven Archetype
- Exporting existing plans to Bamboo Specs
- Bamboo Specs reference
- Bamboo Specs API reference

Tutorial: Create a simple plan with Bamboo Specs v6.1

This guide will help you understand how to create plans with Bamboo Specs. You'll create a simple project and execute it to create a plan in Bamboo.

Before you begin

Make sure you have the following installed:

- JDK 8 or higher
- Maven 3.2 or higher
- Eclipse or IntelliJ IDEA IDE

Note: You may use a different IDE, but tutorial provides examples for the two above

- Bamboo 6.0 or higher

Step 1: Create a project base with Maven

To create a base of the project, execute the following Maven archetype:
```
mvn archetype:generate -B \
   -DarchetypeGroupId=com.atlassian.bamboo \
   -DarchetypeArtifactId=bamboo-specs-archetype \ 
   -DarchetypeVersion=6.1.1 \
   -DgroupId=com.atlassian.bamboo -DartifactId=bamboo-specs-tutorial \
   -Dversion=1.0.0-SNAPSHOT \
   -Dpackage=tutorial -Dtemplate=minimal
```

where:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>archetypeGroupId</td>
<td>Bamboo archetype identifiers</td>
</tr>
<tr>
<td>archetypeArtifactId</td>
<td></td>
</tr>
<tr>
<td>archetypeVersion</td>
<td></td>
</tr>
<tr>
<td>groupId</td>
<td>Project identifiers</td>
</tr>
<tr>
<td>artifactId</td>
<td></td>
</tr>
<tr>
<td>version</td>
<td></td>
</tr>
<tr>
<td>package</td>
<td>Prefix of the Java package that you want to use for the project</td>
</tr>
<tr>
<td>template</td>
<td>Type of code in which the project is generated. For the purpose of this tutorial we're using minimal.</td>
</tr>
</tbody>
</table>

The project is created in the bamboo-specs-tutorial directory:

```
cd bamboo-specs-tutorial
```

**Step 2: Import the project into IDE**

You can now import the project into your integrated development environment (IDE).

**How to import into Eclipse**

1. Run Eclipse.
2. In the main menu, go to File > Import.
3. In the Import dialog, select Maven > Existing Maven Projects.
4. Click Next.
5. Click Browse.
6. Select the bamboo-specs-tutorial directory and click Open.
7. Click Finish.

Eclipse will create a new project and download necessary dependencies (it may take a while).

**How to import into IntelliJ IDEA**

1. Run IntelliJ IDEA.
2. In the main menu, go to File > Open.
3. Select the pom.xml file.
4. Click Open as project.

IntelliJ IDEA will create a new project and download necessary dependencies, which might take a while.

If you want to see how PlanSpec.java files is structured, go to src/main/java/tutorial/PlanSpec.java. You file should have the following structure:

<table>
<thead>
<tr>
<th>PlanSpec</th>
<th>The name of the class. You can use any class name.</th>
</tr>
</thead>
<tbody>
<tr>
<td>BambooSpec</td>
<td>The file is annotated. The annotation is used by the spec-runner Maven plugin to find classes containing Bamboo plans.</td>
</tr>
<tr>
<td>main</td>
<td>With the main method you can run the project as any other Java application.</td>
</tr>
<tr>
<td>BambooServer</td>
<td>The project uses the BambooServer class to publish plans with password authentication. The username and password are read from the .credentials file which is located in the current working directory.</td>
</tr>
</tbody>
</table>
Step 3: Define a job with a script task

1. In the `createPlan` method put a cursor after the `description` method call:

   ```java
   private Plan createPlan() {
       return new Plan(
           project(),
           "Plan Name", "PLANKEY")
           .description("Plan created from (enter repository
           url of your plan)");
   }
   ```

2. Type "." and let your IDE show you available options:

3. Pick the `stages` method and add the `new Stage("Stage 1")` constructor call inside the method's argument (you need to add the import statement for Stage class).

4. Add a job to the stage using the `jobs` method and `new Job()` constructor (add the import statement too). Name the job `Build & run` and use `RUN` for a key:

   ```java
   private Plan createPlan() {
       return new Plan(
           project(),
           "Plan Name", "PLANKEY")
           .description("Plan created from (enter repository
           url of your plan)")
           .stages(
               new Stage("Stage 1")
               .jobs(new Job("Build & run",
               "RUN"));
   }
   ```

5. Let's add a task to the job. Type `.tasks()` and declare a new `ScriptTask()` inside as shown below (add the import statement too). Call `.inlineBody` on the `ScriptTask()`.
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
            .description("Plan created from (enter repository url of your plan)")
            .stages(
                new Stage("Stage 1")
                    .jobs(new Job("Build & run", "RUN")
                        .tasks(
                            new ScriptTask().inlineBody("echo Hello world!")
                        ))
            );
}
com.atlassian.bamboo.specs.api.exceptions.PropertiesValidationException:
Plan or job / Name: can not contain any of those characters: [", &,
', <, >, \] but it is 'Build & run'
at com.atlassian.bamboo.specs.api.validators.common.ImporterUtils.checkNoErrors(ImporterUtils.java:44)
... at tutorial.PlanSpec.createPlan(PlanSpec.java:42)
at tutorial.PlanSpecTest.checkYourPlanOffline(PlanSpecTest.java:12)

where:

<table>
<thead>
<tr>
<th>Plan or job / Name</th>
<th>A path to an invalid element</th>
</tr>
</thead>
<tbody>
<tr>
<td>can not contain ...</td>
<td>Expected and actual value</td>
</tr>
<tr>
<td>but it is ...</td>
<td></td>
</tr>
<tr>
<td>PlanSpec.java:42</td>
<td>The source line containing the error</td>
</tr>
</tbody>
</table>

As you can see, the validation fails because the name of the job contains an invalid & character. Let’s remove it. Your code should look like this now:

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
            .description("Plan created from (enter repository url of your plan)")
            .stages(
                new Stage("Stage 1")
                    .jobs(new Job("Run", "RUN")
                        .tasks(
                            new ScriptTask().inlineBody("echo Hello world!"))()));
}
```

Run the test again to make sure that it passes this time.

**Step 5: Publish Bamboo Specs to the Bamboo server**

- Make sure that your Bamboo instance is up and running
- If you’re not running Bamboo on your local machine (http://localhost:8085), change the bambooUrl variable in the `maven` method.
- We’re assuming that you have an administrator account with username admin and password admin. If you want to use other credentials, you need to update the `.credentials` file located in the root directory of the project.

When you’re sending a plan, Bamboo validates it.

*How to run from Maven*

The pom.xml contains the `publish` profile which executes the spec-runner Maven plugin. So just type:
mvn -Ppublish-specs

How to run from Eclipse
1. Right-click on the PlanSpec class in the Package Explorer view.
2. Click Run as > Java application.

How to run from IntelliJ IDEA
1. Right-click the PlanSpec class in the Project view.
2. Click Run 'PlanSpec.main()'.

The console output looks like this:

```
Publishing plan PLANKEY
Result OK: http://localhost:8085/browse/PRJ-PLANKEY
```

For more verbose logging, add -Dbamboo.specs.log.level=DEBUG program argument when running Bamboo Specs.

**Step 6: Check the results**
1. Go to your Bamboo instance.
2. Open the plan that you created.
3. Go to Actions > Configure plan.
4. Check whether the stage contains a job with the Hello world Script Task.
5. Click Run > Run plan to execute the build.
6. Find the "Hello World!" message in the logs.

Having configuration written as code using Bamboo Specs you can very easily manage all your build plans in Bamboo.

This is very convenient method of managing large Bamboo instances with huge number of plans, publishing plans on Bamboo test instances before promoting changes to production, and tracking configuration changes in version control system.

Read What is Configuration as Code? to learn more about the benefits of using Bamboo Specs.

**Next steps**
Here are some resources that can help you with writing your own Bamboo Specs:

- Create a Bamboo Specs project using Maven Archetype
- Exporting existing plans to Bamboo Specs
- Creating deployment projects in Bamboo Specs
- Bamboo Specs reference
- Bamboo Specs API reference

**.Tutorial: Create a simple plan with Bamboo Specs v6.2**

This guide will help you understand how to create plans with Bamboo Specs. You'll create a simple project and execute it to create a plan in Bamboo.
Before you begin
Make sure you have the following installed:

- JDK 8 or higher
- Maven 3.2 or higher
- Eclipse or IntelliJ IDEA IDE

Note: You may use a different IDE, but tutorial provides examples for the two above

- Bamboo 6.0 or higher

Step 1: Create a project base with Maven
To create a base of the project, execute the following Maven archetype:

```
mvn archetype:generate -B \
    -DarchetypeGroupId=com.atlassian.bamboo \
    -DarchetypeArtifactId=bamboo-specs-archetype \ 
    -DarchetypeVersion=6.2.1 \
    -DgroupId=com.atlassian.bamboo -DartifactId=bamboo-specs \
    -Dversion=1.0.0-SNAPSHOT \ 
    -Dpackage=tutorial -Dtemplate=minimal
```

where:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>archetypeGroupId</td>
<td>Bamboo archetype identifiers</td>
</tr>
<tr>
<td>archetypeArtifactId</td>
<td>Project identifiers</td>
</tr>
<tr>
<td>archetypeVersion</td>
<td></td>
</tr>
<tr>
<td>groupId</td>
<td></td>
</tr>
<tr>
<td>artifactId</td>
<td></td>
</tr>
<tr>
<td>version</td>
<td></td>
</tr>
<tr>
<td>package</td>
<td>Prefix of the Java package that you want to use for the project</td>
</tr>
<tr>
<td>template</td>
<td>Type of code in which the project is generated. For the purpose of this tutorial we're using minimal.</td>
</tr>
</tbody>
</table>

The project is created in the `bamboo-specs-tutorial` directory:

```
cd bamboo-specs
```

Step 2: Import the project into IDE
You can now import the project into your integrated development environment (IDE).

How to import into Eclipse
1. Run Eclipse.
2. In the main menu, go to File > Import.
3. In the Import dialog, select Maven > Existing Maven Projects.
4. Click Next.
5. Click Browse.
6. Select the `bamboo-specs-tutorial` directory and click Open.
7. Click Finish.

Eclipse will create a new project and download necessary dependencies (it may take a while).

**How to import into IntelliJ IDEA**

1. Run IntelliJ IDEA.
2. In the main menu, go to File > Open.
3. Select the `pom.xml` file.
4. Click Open as project.

IntelliJ IDEA will create a new project and download necessary dependencies, which might take a while.

If you want to see how `PlanSpec.java` files are structured, go to src/main/java/tutorial/PlanSpec.java. Your file should have the following structure:

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PlanSpec</td>
<td>The name of the class. You can use any class name.</td>
</tr>
<tr>
<td>BambooSpec</td>
<td>The file is annotated. The annotation is used by the <code>spec-runner</code> Maven plugin to find classes containing Bamboo plans.</td>
</tr>
<tr>
<td><code>main</code></td>
<td>With the <code>main</code> method you can run the project as any other Java application.</td>
</tr>
<tr>
<td>BambooServer</td>
<td>The project uses the <code>BambooServer</code> class to publish plans with password authentication. The username and password are read from the <code>.credentials</code> file which is located in the current working directory.</td>
</tr>
</tbody>
</table>

**Step 3: Define a job with a script task**

1. In the `createPlan` method put a cursor after the `description` method call:

   ```java
   private Plan createPlan() {
       return new Plan(
           project(),
           "Plan Name", "PLANKEY")
               .description("Plan created from (enter repository url of your plan)");
   }
   ```

2. Type `.` and let your IDE show you available options:

3. Pick the `stages` method and add the new `Stage ("Stage 1")` constructor call inside the method's argument (you need to add the import statement for `Stage` class).
4. Add a job to the stage using the `jobs` method and `new Job()` constructor (add the import statement too). Name the job `Build`
& run and use RUN for a key:

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
            .description("Plan created from (enter repository url of your plan)"
            .stages(
                new Stage("Stage 1")
                    .jobs(new Job("Build & run", "RUN")),
                "RUN"));
}
```

5. Let's add a task to the job. Type `.tasks()` and declare a new `ScriptTask()` inside as shown below (add the import statement too). Call `.inlineBody` on the `ScriptTask()`.

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
            .description("Plan created from (enter repository url of your plan)"
            .stages(
                new Stage("Stage 1")
                    .jobs(new Job("Build & run", "RUN")
                        .tasks(
                            new ScriptTask().inlineBody("echo Hello world!"))));
}
```

You can always open a JavaDoc dialog to learn more about given method or class:

- **How to show JavaDoc in Eclipse**
  To download JavaDocs, hold the Ctrl/Cmd key, place the mouse cursor over a method or class name, and click **open declaration**.
  It opens a source editor with a decompiled class file. Eclipse immediately starts downloading sources and JavaDoc JARs in the background and updates editor as soon as it completes.
  To display JavaDocs place the mouse cursor over a class or method name.

- **How to show JavaDoc in IntelliJ IDEA**
  To download JavaDocs hold the Ctrl/Cmd key and click the method or class name.
  It opens a source editor with the decompiled class file. Click the **Download sources** link. IDEA will download sources and JavaDoc JARs.
  To display JavaDocs place the cursor over a method or class name and press Ctrl+J to open a quick documentation pop-up.

---

**Step 4: Validate Bamboo Specs offline**

You can perform offline validation before deploying a plan to Bamboo. Let's try it out by running a unit test.
1. **How to run from Maven**

   `mvn test`

2. **How to run from Eclipse**

   1. Right-click `src/test/java/tutorial/PlanSpecTest.java` in the Package Explorer view.
   2. Select Run as > JUnit test.

3. **How to run from IntelliJ IDEA**

   1. Right-click the `src/test/java/tutorial/PlanSpecTest` class in the Project view.
   2. Click Run 'PlanSpecTest'.

Test fails with the following stack trace:

```
com.atlassian.bamboo.specs.api.exceptions.PropertiesValidationException:
Plan or job / Name: can not contain any of those characters: [", &, ", <, >, \] but it is 'Build & run'
at com.atlassian.bamboo.specs.api.validators.common.ImporterUtils.checkNoErrors(ImporterUtils.java:44)
... at tutorial.PlanSpec.createPlan(PlanSpec.java:42)
at tutorial.PlanSpecTest.checkYourPlanOffline(PlanSpecTest.java:12)
```

where:

<table>
<thead>
<tr>
<th>Plan or job / Name</th>
<th>A path to an invalid element</th>
</tr>
</thead>
<tbody>
<tr>
<td>can not contain ...</td>
<td>Expected and actual value</td>
</tr>
<tr>
<td>but it is ...</td>
<td></td>
</tr>
<tr>
<td>PlanSpec.java:42</td>
<td>The source line containing the error</td>
</tr>
</tbody>
</table>

As you can see, the validation fails because the name of the job contains an invalid `&` character. Let's remove it. Your code should look like this now:

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY"
        .description("Plan created from (enter repository url of your plan)")
        .stages(
            new Stage("Stage 1")
            .jobs(new Job("Run", "RUN")
            .tasks(
                new ScriptTask().inlineBody("echo Hello world!")));
    }
```

Run the test again to make sure that it passes this time.

**Step 5: Publish Bamboo Specs to the Bamboo server**
When you're sending a plan, Bamboo validates it.

▼ **How to run from Maven**
   The pom.xml contains the 'publish-specs' profile which executes the spec-runner Maven plugin. So just type:
   ```
mvn -Ppublish-specs
   ```

▼ **How to run from Eclipse**
   1. Right-click on the PlanSpec class in the Package Explorer view.
   2. Click Run as > Java application.

▼ **How to run from IntelliJ IDEA**
   1. Right-click the PlanSpec class in the Project view.
   2. Click Run 'PlanSpec.main()'.

The console output looks like this:

```
Publishing plan PLANKEY
Result OK: http://localhost:8085/browse/PRJ-PLANKEY
```

For more verbose logging, add -Dbamboo.specs.log.level=DEBUG program argument when running Bamboo Specs.

**Step 6: Check the results**

1. Go to your Bamboo instance.
2. Open the plan that you created.
3. Go to Actions > Configure plan.
4. Check whether the stage contains a job with the Hello world Script Task.
5. Click Run > Run plan to execute the build.
6. Find the "Hello World!" message in the logs.

Having configuration written as code using Bamboo Specs you can very easily manage all your build plans in Bamboo.

This is very convenient method of managing large Bamboo instances with huge number of plans, publishing plans on Bamboo test instances before promoting changes to production, and tracking configuration changes in version control system.

Read What is Configuration as Code? to learn more about the benefits of using Bamboo Specs.

**Next steps**

Here are some resources that can help you with writing your own Bamboo Specs:

- Create a Bamboo Specs project using Maven Archetype
- Exporting existing plans to Bamboo Specs
- Creating deployment projects in Bamboo Specs
- Bamboo Specs reference
- Bamboo Specs API reference

**Tutorial: Bamboo Java Specs stored in Bitbucket Server**
This guide will show you how you can store Bamboo Specs in a Git repository on Bitbucket Server. This approach allows to automatically build and execute Bamboo Specs on every push you make to a Git repository.

### On this page
- Before you begin
- Step 1: Create a Git repository in Bitbucket Server and clone it locally
- Step 2: Create a linked repository in Bamboo
- Step 3: Enable processing of Bamboo Specs in your repository
- Step 4: Create Bamboo Specs project using Maven
- Step 5: Commit and push code changes to Bitbucket Server
- Step 6: Check if plan was created
- Next steps

### Related links
- Bamboo Specs reference
- Bamboo Specs API reference
- Create a Bamboo Specs project using Maven Archetype

### Before you begin
- Make sure you have the required software installed.
  - See the whole list...
    - Bamboo 6.2 or later
    - Bitbucket Server 4.0 or later
    - JDK 8 or higher
    - Maven 3.2 or higher
- Set up an application link between Bamboo and Bitbucket Server. See Integrating Bamboo with Bitbucket Server.
- If you don't know Bamboo Specs yet, make sure to read our introductory tutorial: Tutorial: Create a simple plan with Bamboo Java Specs.

### Step 1: Create a Git repository in Bitbucket Server and clone it locally
1. In Bitbucket Server, open the Projects page.
2. Click the Create project.
3. Select Bamboo for project name and key and click Create project.
   - You see that the project has no repositories.
4. Click Create repository.
5. Give your new repository the name tutorial and click Create repository.

You've just created a new empty repository. Use the `git clone` command to create a clone on your computer. For example:

```
git clone http://admin@localhost:7990/scm/bamboo/tutorial.git
```

### Step 2: Create a linked repository in Bamboo
1. Open Bamboo and go to
   - Linked repositories.
2. Click Add repository.
3. Select a Bitbucket Server / Stash repository type.
4. Choose a name for your repository.
5. From the Server drop-down, select your Bitbucket Server.
6. In the Web repository section, select the Bamboo / tutorial repository from the Web repository drop-down.
7. Click Save repository.

Your new repository is created and you can start using it in Bamboo.
Step 3: Enable processing of Bamboo Specs in your repository

By default Bamboo will not look for Bamboo Specs in the Git repository until you explicitly tell it to do so. Let's do it now:

1. Go to
   - Linked repositories.
2. Select your repository.
3. In the Bamboo Specs tab, enable **Scan for Bamboo Specs**.

In this tutorial we simply grant access to all projects in the Bamboo instance. You can fine-tune project access, see Enabling repository-stored Bamboo Specs how to do this.

Now, the Bamboo is ready to execute Bamboo Specs if it will be committed to the repository. Let's prepare some code.

Step 4: Create Bamboo Specs project using Maven

1. Go to the empty Git repository you cloned in step 1:

   ```
   cd tutorial
   ```

2. Use the Maven archetype to create a project template. For the purpose of this tutorial, type:

   ```
   mvn archetype:generate -B  
   -DarchetypeGroupId=com.atlassian.bamboo  
   -DarchetypeArtifactId=bamboo-specs-archetype  
   -DarchetypeVersion=6.2.1  
   -DgroupId=com.my.company -DartifactId=bamboo-specs  
   -Dversion=1.0.0-SNAPSHOT -Dpackage=com.my.company
   ```

   Your project is created. You can open it in IDE, such as Eclipse or IDEA if you want to see how the project looks like. Also see the introductory Tutorial: Create a simple plan with Bamboo Specs v6.2 to get familiar with the code structure.

Step 5: Commit and push code changes to Bitbucket Server

1. Add created `bamboo-specs` directory to VCS and push changes to the server:

   ```
   git add bamboo-specs
   git commit -m "Initial commit of Bamboo Specs"
   git push
   ```

As soon as you push your code changes to Bitbucket Server, Bamboo will get notified about a new commit available. Bamboo will checkout your project, compile it and execute Bamboo Specs in a sandbox environment. Execution of Bamboo Specs will create or update configuration of plans or deployment projects accordingly.

Step 6: Check if plan was created
1. Open your Bamboo instance.
2. From the header, select **Build > All build plans**.
3. Open the project and plan you've just created.

   ![All configuration options are disabled because entire plan configuration is now managed by Bamboo Specs from your Bitbucket repository.](image)

4. Click **Run plan** to execute the build.
5. Find the "Hello World!" message in the logs.

### Next steps

Here are some resources that can help you with writing your own Bamboo Specs:

- Create a Bamboo Specs project using Maven Archetype
- Exporting existing plans to Bamboo Specs
- Creating deployment projects in Bamboo Specs
- Bamboo Specs reference
- Bamboo Specs API reference

## Tutorial: Bamboo Java Specs stored in Bitbucket Server v6.3

This guide will show you how you can store Bamboo Specs in a Git repository on Bitbucket Server. This approach allows to automatically build and execute Bamboo Specs on every push you make to a Git repository.

### On this page

- Before you begin
- Step 1: Create a Git repository in Bitbucket Sever and clone it locally
- Step 2: Create a linked repository in Bamboo
- Step 3: Enable processing of Bamboo Specs in your repository
- Step 4: Create Bamboo Specs project using Maven
- Step 5: Commit and push code changes to Bitbucket Server
- Step 6: Check if plan was created
- Next steps

### Related links

- Bamboo Specs reference
- Bamboo Specs API reference
- Create a Bamboo Specs project using Maven Archetype

---

### Before you begin

- Make sure you have the required software installed.
  - See the whole list...
  - Bamboo 6.2 or later
  - Bitbucket Server 4.0 or later
  - JDK 8 or higher
  - Maven 3.2 or higher
- Set up an application link between Bamboo and Bitbucket Server. See [Integrating Bamboo with Bitbucket Server](#).
- If you don't know Bamboo Specs yet, make sure to read our introductory tutorial: [Tutorial: Create a simple plan with Bamboo Java Specs](#).

### Step 1: Create a Git repository in Bitbucket Sever and clone it locally

1. In Bitbucket Server, open the **Projects** page.
2. Click the **Create project**.
3. Select **Bamboo** for project name and key and click **Create project**. You see that the project has no repositories.
4. Click **Create repository**.
5. Give your new repository the name `tutorial` and click **Create repository**.

You've just created a new empty repository. Use the `git clone` command to create a clone on your computer. For example:
git clone http://admin@localhost:7990/scm/bamboo/tutorial.git

**Step 2: Create a linked repository in Bamboo**

1. Open Bamboo and go to
   - Linked repositories.
2. Click Add repository.
3. Select a Bitbucket Server / Stash repository type.
4. Choose a name for your repository.
5. From the Server drop-down, select your Bitbucket Server.
6. In the **Web repository** section, select the **Bamboo / tutorial** repository from the Web repository drop-down.
7. Click **Save repository**.

Your new repository is created and you can start using it in Bamboo.

**Step 3: Enable processing of Bamboo Specs in your repository**

By default Bamboo will not look for Bamboo Specs in the Git repository until your explicitly tell it to do so. Let's do it now:

1. Go to
   - Linked repositories.
2. Select your repository.
3. In the Bamboo Specs tab, enable **Scan for Bamboo Specs**.

In this tutorial we simply grant access to all projects in the Bamboo instance. You can fine-tune project access, see [Enabling repository-stored Bamboo Specs](#) how to do this.

Now, the Bamboo is ready to execute Bamboo Specs if it will be committed to the repository. Let's prepare some code.

**Step 4: Create Bamboo Specs project using Maven**

1. Go to the empty Git repository you cloned in step 1:
   
   ```
   cd tutorial
   ```

2. Use the Maven archetype to create a project template. For the purpose of this tutorial, type:
   
   ```
   mvn archetype:generate -B \
   -DarchetypeGroupId=com.atlassian.bamboo \
   -DarchetypeArtifactId=bamboo-specs-archetype \
   -DarchetypeVersion=6.2.1 \
   -DgroupId=com.my.company -DartifactId=bamboo-specs \
   -Dversion=1.0.0-SNAPSHOT -Dpackage=com.my.company
   ```

Your project is created. You can open it in IDE, such as Eclipse or IDEA if you want to see how the project looks like. Also see the
introductory Tutorial: Create a simple plan with Bamboo Specs v6.2 to get familiar with the code structure.

**Step 5: Commit and push code changes to Bitbucket Server**

1. Add created `bamboo-specs` directory to VCS and push changes to the server:

   ```
   git add bamboo-specs
   git commit -m "Initial commit of Bamboo Specs"
   git push
   ```

As soon as you push your code changes to Bitbucket Server, Bamboo will get notified about a new commit available.

Bamboo will checkout your project, compile it and execute Bamboo Specs in a sandbox environment.

Execution of Bamboo Specs will create or update configuration of plans or deployment projects accordingly.

**Step 6: Check if plan was created**

1. Open your Bamboo instance.
2. From the header, select **Build > All build plans**.
3. Open the project and plan you've just created.

   ```
   All configuration options are disabled because entire plan configuration is now managed by Bamboo Specs from your Bitbucket repository.
   ```

4. Click **Run plan** to execute the build.
5. Find the "Hello World!" message in the logs.

**Next steps**

Here are some resources that can help you with writing your own Bamboo Specs:

- Create a Bamboo Specs project using Maven Archetype
- Exporting existing plans to Bamboo Specs
- Creating deployment projects in Bamboo Specs
- Bamboo Specs reference

.Tutorial: Bamboo Java Specs stored in Bitbucket Server v6.4

This guide will show you how you can store Bamboo Specs in a Git repository on Bitbucket Server. This approach lets you automatically build and execute Bamboo Specs on every push you make to a Git repository.

**Before you begin**

- Make sure you have the required software installed.
  - See the whole list...
    - Bamboo 6.2 or later
    - Bitbucket Server 4.0 or later
    - JDK 8 or higher
    - Maven 3.2 or higher
- Set up an application link between Bamboo and Bitbucket Server. See Integrating Bamboo with Bitbucket Server.
- If you're not familiar with Bamboo Specs, make sure you read our introductory tutorial: Create a simple plan with Bamboo Java Specs.

**Step 1: Create a Git repository in Bitbucket Server and clone it locally**

1. In Bitbucket Server, open the **Projects** page.
2. Click **Create project**.
3. Enter Bamboo for project name and key and click **Create project**.
4. Click **Create repository**.
5. Give your new repository the name tutorial and click **Create repository**.

You've just created a new empty repository. Use the `git clone` command to create a clone on your computer. For example:
Step 2: Create a linked repository in Bamboo

1. Open Bamboo and go to
   - Linked repositories.
2. Click Add repository.
3. Select a Bitbucket Server / Stash repository type.
4. Choose a name for your repository.
5. From the Server drop-down, select your Bitbucket Server.
6. In the Web repository section, select the Bamboo / tutorial repository from the Web repository drop-down.
7. Click Save repository.

Your new repository is created and you can start using it in Bamboo.

Step 3: Enable processing of Bamboo Specs in your repository

By default Bamboo will not look for Bamboo Specs in the Git repository until you explicitly tell it to do so. Let’s do it now:

1. Go to
   - Linked repositories.
2. Select your repository.
3. In the Bamboo Specs tab, enable Scan for Bamboo Specs.

In this tutorial we simply grant access to all projects in the Bamboo instance. You can fine-tune project access. See Enabling repository-stored Bamboo Specs v6.2.

Now, Bamboo is ready to execute Bamboo Specs when the relevant code is committed to the repository. Let’s create some code.

Step 4: Create Bamboo Specs project using Maven

1. Go to the empty Git repository you cloned in step 1:
   ```
   cd tutorial
   ```
2. Use the Maven archetype to create a project template. For the purpose of this tutorial, type:

   ```
   mvn archetype:generate -B \
   -DarchetypeGroupId=com.atlassian.bamboo \
   -DarchetypeArtifactId=bamboo-specs-archetype \
   -DarchetypeVersion=6.2.1 \
   -DgroupId=com.my.company -DartifactId=bamboo-specs \
   -Dversion=1.0.0-SNAPSHOT -Dpackage=com.my.company
   ```

Your project is created. You can open it in an IDE, such as Eclipse or IDEA, if you want to see how the project is set up. For more information on the code structure, take a look at Tutorial: Create a simple plan with Bamboo Specs.

Step 5: Commit and push code changes to Bitbucket Server

1. Add created `bamboo-specs` directory to VCS and push changes to the server:
git add bamboo-specs
git commit -m "Initial commit of Bamboo Specs"
git push

As soon as you push your code changes to Bitbucket Server, Bamboo will get notified about a new commit available. Bamboo will checkout your project, compile it and execute Bamboo Specs in a sandbox environment. Execution of Bamboo Specs will create or update configuration of plans or deployment projects accordingly.

**Step 6: Check to see if the plan was created**

1. Open your Bamboo instance.
2. From the header, select **Build > All build plans**.
3. Open the project and plan you've just created.

   All configuration options are disabled because entire plan configuration is now managed by Bamboo Specs from your Bitbucket repository.

4. Click **Run plan** to execute the build.
5. Find the "Hello World!" message in the logs.

**Next steps**

Here are some resources that can help you with writing your own Bamboo Specs:

- Create a Bamboo Specs project using Maven Archetype
- Exporting existing plans to Bamboo Specs
- Creating deployment projects in Bamboo Specs
- Bamboo Specs reference

**Tutorial: Bamboo Specs stored in Bitbucket Server v6.2**

This guide will show you how you can store Bamboo Specs in a Git repository on Bitbucket Server. This approach allows to automatically build and execute Bamboo Specs on every push you make to a Git repository.

**Before you begin**

- Make sure you have the required software installed.
  - See the whole list...
    - Bamboo 6.2 or later
    - Bitbucket Server 4.0 or later
    - JDK 8 or higher
    - Maven 3.2 or higher

- Set up an application link between Bamboo and Bitbucket Server. See [Integrating Bamboo with Bitbucket Server](https://confluence.atlassian.com/display/BB/Integrating+Bamboo+with+Bitbucket+Server).
If you don't know Bamboo Specs yet, make sure to read our introductory tutorial: Tutorial: Create a simple plan with Bamboo Java Specs.

Step 1: Create a Git repository in Bitbucket Server and clone it locally

1. In Bitbucket Server, open the Projects page.
2. Click the Create project.
3. Select Bamboo for project name and key and click Create project.
   You see that the project has no repositories.
4. Click Create repository.
5. Give your new repository the name tutorial and click Create repository.

You've just created a new empty repository. Use the `git clone` command to create a clone on your computer. For example:

```
git clone http://admin@localhost:7990/scm/bamboo/tutorial.git
```

Step 2: Create a linked repository in Bamboo

1. Open Bamboo and go to
   
   > Linked repositories.
2. Click Add repository.
3. Select a Bitbucket Server / Stash repository type.
4. Choose a name for your repository.
5. From the Server drop-down, select your Bitbucket Server.
6. In the Web repository section, select the Bamboo / tutorial repository from the Web repository drop-down.
7. Click Save repository.

Your new repository is created and you can start using it in Bamboo.

Step 3: Enable processing of Bamboo Specs in your repository

By default Bamboo will not look for Bamboo Specs in the Git repository until your explicitly tell it to do so. Let's do it now:

1. Go to
   
   > Linked repositories.
2. Select your repository.
3. In the Bamboo Specs tab, enable Scan for Bamboo Specs.

In this tutorial we simply grant access to all projects in the Bamboo instance. You can fine-tune project access, see Enabling repository-stored Bamboo Specs how to do this.

Now, the Bamboo is ready to execute Bamboo Specs if it will be committed to the repository. Let's prepare some code.

Step 4: Create Bamboo Specs project using Maven

1. Go to the empty Git repository you cloned in step 1:

```
cd tutorial
```

2. Use the Maven archetype to create a project template. For the purpose of this tutorial, type:

```
It's important to create Bamboo Specs in the bamboo-specs directory, under the repository root.
```
Your project is created. You can open it in IDE, such as Eclipse or IDEA if you want to see how the project looks like. Also see the introductory Tutorial: Create a simple plan with Bamboo Specs v6.2 to get familiar with the code structure.

**Step 5: Commit and push code changes to Bitbucket Server**

1. Add created `bamboo-specs` directory to VCS and push changes to the server:

   ```
   git add bamboo-specs
   git commit -m "Initial commit of Bamboo Specs"
   git push
   ```

   As soon as you push your code changes to Bitbucket Server, Bamboo will get notified about a new commit available.

   Bamboo will checkout your project, compile it and execute Bamboo Specs in a sandbox environment.

   Execution of Bamboo Specs will create or update configuration of plans or deployment projects accordingly.

**Step 6: Check if plan was created**

1. Open your Bamboo instance.
2. From the header, select Build > All build plans.
3. Open the project and plan you've just created.

   All configuration options are disabled because entire plan configuration is now managed by Bamboo Specs from your Bitbucket repository.

4. Click Run plan to execute the build.
5. Find the "Hello World!" message in the logs.

**Next steps**

Here are some resources that can help you with writing your own Bamboo Specs:

- Create a Bamboo Specs project using Maven Archetype
- Exporting existing plans to Bamboo Specs
- Creating deployment projects in Bamboo Specs
- Bamboo Specs reference

**Bamboo YAML Specs**

As an alternative to using Bamboo Java Specs, Bamboo 6.3 allows you to create simple plans using Bamboo YAML Specs in no time. Just use one of the templates we provide and you're ready to start committing your files to a repository.

**How it works**

Bamboo YAML Specs is another Bamboo Specs format supported by Bamboo next to Bamboo Specs Java. Once you have defined your plan configuration in YAML, you need to allow your repository to scan for Bamboo Specs.

Bamboo always looks for YAML Specs first. If it doesn't find YAML Specs, Bamboo tries to find and process Java Specs.
In the repository you specified, Bamboo looks for `bamboo-specs/bamboo.yml` or `bamboo-specs/bamboo.yaml` files to fetch your configuration. Linked repository needs to have permissions to create plans within given project in order to process YAML definition and create a plan.

A new plan created using Bamboo YAML Specs does not have any explicit permissions granted - only administrators will have access to it. You can’t use YAML Specs to define plan-level permissions. We advise you to use project-level permissions. Contrary to Java Specs, YAML Specs can’t create projects.

In Bamboo YAML Specs, artifacts are shared by default. Artifacts are downloaded between stages, e.g. user Defines Stage 1 with Artifact A, Stage 2 with Artifact B and Stage 3. This means that Stage 2 will download Artifact A from Stage 1 and Stage 3 will download both Artifact A and B from previous stages.

**YAML Format**

Bamboo Specs YAML allows for a single plan definition in a single YAML file and accepts the following format:

```yaml
---
project:
  key: DRAGON
plan:
  key: SLAYER
  name: Dragon Slayer Quest
# List of plan's stages
stages:
  # List of stage's jobs
  jobs:
    # Scripts which are going to be executed within this job
    scripts:
      - echo 'Going to kill the red dragon, watch me'
      - sleep 1
      - echo 'Nailed it'
    # Job's requirements. Only matching type 'exists' is supported
    requirements:
      - isDragonLazy
    # Job's artifacts. All artifacts are shared ones.
    artifacts:
      - name: Red dragon's head
        path: dragon/red/head
    # Job's test parsers.
    testParsers:
      - type: mocha
        testResults: '**/mocha/*.json'
      - type: junit
        testResults: '**/junit/*.xml'
...
```

Bamboo YAML Specs allows for configuring test parsers with a simplified format. You can use one of the following configurations:

```yaml
testParsers:
  - mocha
  - junit
```
testParsers:
- type: mocha
testResults: '**/mocha/*.json'
- type: junit
testResults: '**/junit/*.xml'

Default settings

Here’s the default settings of plans created using YAML Specs. These settings cannot be changed.

- Bamboo YAML plan check-out starts with checking out a repository in which it’s defined
- notifications are sent to committers and watchers of the plan when plan fails
- artifacts sharing is turned on
- plan branches are created automatically with plan branch expiry set for 30 days
- YAML plans use Bitbucket Server triggers

.Bamboo YAML Specs v6.3

As an alternative to using Bamboo Java Specs, Bamboo 6.3 allows you to create simple plans using Bamboo YAML Specs in no time. Just use one of the templates we provide and you’re ready to start committing your files to a repository.

How it works

Bamboo YAML Specs is another Bamboo Specs format supported by Bamboo next to Bamboo Specs Java. Once you have defined your plan configuration in YAML, you need to allow your repository to scan for Bamboo Specs.

In the repository you specified, Bamboo looks for ${repo-home}/bamboo-specs/bamboo.yml or ${repo-home}/bamboo-specs/bamboo.yaml files to fetch your configuration. Linked repository needs to have permissions to create plans within given project in order to process YAML definition and create a plan.

A new plan created using Bamboo YAML Specs does not have any explicit permissions granted - only administrators will have access to it. You can’t use YAML Specs to define plan-level permissions. We advise you to use project-level permissions. Contrary to Java Specs, YAML Specs can’t create projects.

In Bamboo YAML Specs, artifacts are shared by default. Artifacts are downloaded between stages, e.g. user Defines Stage 1 with Artifact A, Stage 2 with Artifact B and Stage 3. This means that Stage 2 will download Artifact A from Stage 1 and Stage 3 will download both Artifact A and B from previous stages.
**YAML Format**

Bamboo Specs YAML allows for a single plan definition in a single YAML file and accepts the following format:

```yaml
---
project:
  key: DRAGON
plan:
  key: SLAYER
  name: Dragon Slayer Quest
# List of plan's stages
stages:
# List of stage's jobs
  jobs:
# Scripts which are going to be executed within this job
    scripts:
      - echo 'Going to kill the red dragon, watch me'
      - sleep 1
      - echo 'Nailed it'
# Job's requirements. Only matching type 'exists' is supported
    requirements:
      - isDragonLazy
# Job's artifacts. All artifacts are shared ones.
    artifacts:
      - name: Red dragon's head
        path: dragon/red/head
# Job's test parsers.
    testParsers:
      - type: mocha
        testResults: '**/mocha/*.json'
      - type: junit
        testResults: '**/junit/*.xml'
```

Bamboo YAML Specs allows for configuring test parsers with a simplified format. You can use one of the following configurations:

```yaml
testParsers:
  - mocha
  - junit
```

```yaml
testParsers:
  - type: mocha
    testResults: '**/mocha/*.json'
  - type: junit
    testResults: '**/junit/*.xml'
```

.Bamboo YAML Specs v6.4

As an alternative to using Bamboo Java Specs, Bamboo 6.3 allows you to create simple plans using Bamboo YAML Specs in no time. Just use one of the templates we provide and you’re ready to start committing your files to a repository.

How it works

Bamboo YAML Specs is another Bamboo Specs format supported by Bamboo next to Bamboo Specs Java. Once you have defined your plan configuration in YAML, you need to allow your repository to scan for Bamboo Specs.

Bamboo always looks for YAML Specs first. If it doesn’t find YAML Specs, Bamboo tries to find and process Java Specs.

In the repository you specified, Bamboo looks for `bamboo-specs/bamboo.yml` or `bamboo-specs/bamboo.yaml` files to fetch your configuration. Linked repository needs to have permissions to create plans within given project in order to process YAML definition and create a plan.

A new plan created using Bamboo YAML Specs does not have any explicit permissions granted - only administrators will have access to it. You can’t use YAML Specs to define plan-level permissions. We advise you to use project-level permissions. Contrary to Java Specs, YAML Specs can’t create projects.

In Bamboo YAML Specs, artifacts are shared by default. Artifacts are downloaded between stages, e.g. user Defines Stage 1 with Artifact A, Stage 2 with Artifact B and Stage 3. This means that Stage 2 will download Artifact A from Stage 1 and Stage 3 will download both Artifact A and B from previous stages.

YAML Format

Bamboo Specs YAML allows for a single plan definition in a single YAML file and accepts the following format:
---

project:
  key: DRAGON

plan:
  key: SLAYER
  name: Dragon Slayer Quest

# List of plan's stages
stages:
  # List of stage's jobs
  - jobs:
    # Scripts which are going to be executed within this job
    - scripts:
      - echo 'Going to kill the red dragon, watch me'
      - sleep 1
      - echo 'Nailed it'
    # Job's requirements. Only matching type 'exists' is supported
    requirements:
      - isDragonLazy
    # Job's artifacts. All artifacts are shared ones.
    artifacts:
      - name: Red dragon's head
        path: dragon/red/head
    # Job's test parsers.
    testParsers:
      - type: mocha
        testResults: '**/mocha/*.json'
      - type: junit
        testResults: '**/junit/*.xml'

...
testParsers:
- type: mocha
testResults:
  - xxx.json
- type: junit
testResults:
  - '**/test-reports/*.xml'
  - '**/custom-test-reports/*.xml'

Default settings

Here’s the default settings of plans created using YAML Specs. These settings cannot be changed.

- Bamboo YAML plan check-out starts with checking out a repository in which it's defined
- Notifications are sent to committers and watchers of the plan when plan fails
- Artifacts sharing is turned on
- Plan branches are created automatically with plan branch expiry set for 30 days

.Bamboo YAML Specs v6.5

As an alternative to using Bamboo Java Specs, Bamboo 6.3 allows you to create simple plans using Bamboo YAML Specs in no time. Just use one of the templates we provide and you’re ready to start committing your files to a repository.

How it works

Bamboo YAML Specs is another Bamboo Specs format supported by Bamboo next to Bamboo Specs Java. Once you have defined your plan configuration in YAML, you need to allow your repository to scan for Bamboo Specs.

In the repository you specified, Bamboo always looks for YAML Specs first. If it doesn’t find YAML Specs, Bamboo tries to find and process Java Specs.

In the repository you specified, Bamboo always looks for bamboo-specs/bamboo.yml or bamboo-specs/bamboo.yaml files to fetch your configuration. Linked repository needs to have permissions to create plans within given project in order to process YAML definition and create a plan.

A new plan created using Bamboo YAML Specs does not have any explicit permissions granted - only administrators will have access to it. You can't use YAML Specs to define plan-level permissions. We advise you to use project-level permissions. Contrary to Java Specs, YAML Specs can't create projects.

In Bamboo YAML Specs, artifacts are shared by default. Artifacts are downloaded between stages, e.g user Defines Stage 1 with Artifact A, Stage 2 with Artifact B and Stage 3. This means that Stage 2 will download Artifact A from Stage 1 and Stage 3 will download both Artifact A and B from previous stages.

YAML Format

Bamboo Specs YAML allows for a single plan definition in a single YAML file and accepts the following format:
---

project:
  key: DRAGON

plan:
  key: SLAYER
  name: Dragon Slayer Quest

# List of plan's stages
stages:
# List of stage's jobs
  jobs:
    # Scripts which are going to be executed within this job
    - scripts:
        - echo 'Going to kill the red dragon, watch me'
        - sleep 1
        - echo 'Nailed it'

    # Job's requirements. Only matching type 'exists' is supported
    requirements:
        - isDragonLazy

    # Job's artifacts. All artifacts are shared ones.
    artifacts:
        - name: Red dragon's head
          path: dragon/red/head

    # Job's test parsers.
    testParsers:
        - type: mocha
          testResults: '**/mocha/*.json'
        - type: junit
          testResults: '**/junit/*.xml'

...
**testParsers:**
- type: mocha
testResults:
  - xxx.json
- type: junit
testResults:
  - '**/test-reports/*.xml'
  - '**/custom-test-reports/*.xml'

**Default settings**

Here's the default settings of plans created using YAML Specs. These settings cannot be changed.

- Bamboo YAML plan check-out starts with checking out a repository in which it's defined
- notifications are sent to committers and watchers of the plan when plan fails
- artifacts sharing is turned on
- plan branches are created automatically with plan branch expiry set for 30 days
- YAML plans use Bitbucket Server triggers

**Bamboo YAML Specs v6.6**

As an alternative to using Bamboo Java Specs, Bamboo 6.3 allows you to create simple plans using Bamboo YAML Specs in no time. Just use one of the templates we provide and you're ready to start committing your files to a repository.

**How it works**

Bamboo YAML Specs is another Bamboo Specs format supported by Bamboo next to Bamboo Specs Java. Once you have defined your plan configuration in YAML, you need to allow your repository to scan for Bambook YAML Specs.

In the repository you specified, Bamboo looks for `bamboo-specs/bamboo.yml` or `bamboo-specs/bamboo.yaml` files to fetch your configuration. Linked repository needs to have permissions to create plans within given project in order to process YAML definition and create a plan.

A new plan created using Bamboo YAML Specs does not have any explicit permissions granted - only administrators will have access to it. You can't use YAML Specs to define plan-level permissions. We advise you to use project-level permissions. Contrary to Java Specs, YAML Specs can't create projects.

In Bamboo YAML Specs, artifacts are shared by default. Artifacts are downloaded between stages, e.g. user Defines Stage 1 with Artifact A, Stage 2 with Artifact B and Stage 3. This means that Stage 2 will download Artifact A from Stage 1 and Stage 3 will download both Artifact A and B from previous stages.

In Bamboo YAML Specs, artifacts are also required by default. This means that a build fails if the artifact can't be published.

**YAML Format**

Bamboo Specs YAML allows for a single plan definition in a single YAML file and accepts the following format:
---
project:
  key: DRAGON
plan:
  key: SLAYER
  name: Dragon Slayer Quest
# List of plan's stages
stages:
  # List of stage's jobs
  jobs:
    # Scripts which are going to be executed within this job
    scripts:
      - echo 'Going to kill the red dragon, watch me'
      - sleep 1
      - echo 'Nailed it'
    # Job's requirements. Only matching type 'exists' is supported
    requirements:
      - isDragonLazy
    # Job's artifacts. All artifacts are shared ones.
    artifacts:
      - name: Red dragon's head
        path: dragon/red/head
    # Job's test parsers.
    testParsers:
      - type: mocha
        testResults: '**/mocha/*.json'
      - type: junit
        testResults: '**/junit/*.xml'
...

Bamboo YAML Specs allows for configuring test parsers with a simplified format. You can use one of the following configurations:

```
testParsers:
  - mocha
  - junit
```

```
testParsers:
  - type: mocha
    testResults: '**/mocha/*.json'
  - type: junit
    testResults: '**/junit/*.xml'
```
testParsers:
  - type: mocha
testResults:
  - xxx.json
-testResults:
  - '**/test-reports/*.xml'
  - '**/custom-test-reports/*.xml'

Default settings

Here’s the default settings of plans crated using YAML Specs. These settings cannot be changed.

- Bamboo YAML plan check-out starts with checking out a repository in which it's defined
- notifications are sent to committers and watchers of the plan when plan fails
- artifacts sharing is turned on
- plan branches are created automatically with plan brach expiry set for 30 days
- YAML plans use Bitbucket Server triggers

.Bamboo YAML v6.2

As an alternative to using Bamboo Specs, Bamboo 6.2 allows you to create simple plans using YAML.

This feature is released as a preview only and its scope might undergo changes in the future. We’d appreciate any feedback regarding Bamboo YAML that you might have so that we can shape this functionality the way that will suit your work best.

Possibility of using YAML for creating plans in available by default in Bamboo 6.2. The format of Bamboo YAML follows the one of Bitbucket Pipelines, however, it might change in the future releases. Currently, we’re looking into expanding the syntax with concurrent tasks and artifact sharing.

Right now Bamboo allows you to create plans that have one stage and one job only using YAML. We currently do not provide support for branches and use the master only.

Using Bamboo YAML, you can create and update plans which will have the project key PIPELINE{number} where {number} is the unique ID of the repository.

When using repository-stored Bamboo Specs, Bamboo searches for the bamboo-specs directory and runs the Bamboo Specs from it. Bamboo YAML works in a similar manner but searches for a file named bitbucket-pipelines.yml in the root directory. If both repository-stored Bamboo Specs and Bamboo YAML directories exist in a project, Bamboo will use repository-stored Bamboo Specs as the approaches are mutual exclusive.

Your specs defined with Bamboo YAML run in a docker container, which you can define using the image attribute.

Example

Here’s an example of a simple Bamboo plan created with YAML:

A job is starting docker container from image. If there is no image defined, a default image is used: if no image is defined default at lassian/default-image:latest.

Once started, it will run script lines defined in step/script.
Bamboo Specs YAML

.Bamboo Specs YAML templates v6.3

Bamboo Specs YAML format

Bamboo Specs YAML allows for a single plan definition in a single YAML file and accepts the following format:

```yaml
pipelines:
  branches:
    master:
      - step:
          image: golang
          script:
            - source
              bitbucket-pipelines-go.sh
            - cd
              $(IMPORT_PATH)/stringutil
            - go get
            - go build
            - go test
            - cd
              $(IMPORT_PATH)/hello
            - go install
            - hello
```
---

project:
  key: DRAGON

plan:
  key: SLAYER
  name: Dragon Slayer Quest

# List of plan's stages

stages:
  # List of stage's jobs
  - jobs:
    # Scripts which are going to be executed within this job
    - scripts:
      - echo 'Going to kill the red dragon, watch me'
      - sleep 1
      - echo 'Nailed it'

# Job's requirements. Only matching type 'exists' is supported
requirements:
  - isDragonLazy

# Job's artifacts. All artifacts are shared ones.
artifacts:
  - name: Red dragon's head
    path: dragon/red/head

# Job's test parsers.

testParsers:
  - type: mocha
    testResults: '**/mocha/*.json'
  - type: junit
    testResults: '**/junit/*.xml'

...

Bamboo YAML Specs allows for configuring test parsers with a simplified format. You can use one of the following configurations:

```yaml
testParsers:
  - mocha
  - junit
```

```yaml
testParsers:
  - type: mocha
    testResults: '**/mocha/*.json'
  - type: junit
    testResults: '**/junit/*.xml'
```
Bamboo Specs YAML format v6.3

Bamboo Specs YAML allows for a single plan definition in a single YAML file and accepts the following format:

```yaml
---
project:
  key: DRAGON
plan:
  key: SLAYER
  name: Dragon Slayer Quest
# List of plan's stages
stages:
# List of stage's jobs
  - jobs:
    # Scripts which are going to be executed within this job
      - scripts:
        - echo 'Going to kill the red dragon, watch me'
        - sleep 1
        - echo 'Nailed it'
    # Job's requirements. Only matching type 'exists' is supported
    requirements:
      - isDragonLazy
    # Job's artifacts. All artifacts are shared ones.
    artifacts:
      - name: Red dragon's head
        path: dragon/red/head
    # Job's test parsers.
    testParsers:
      - type: mocha
      - type: junit
        testResults: '**/junit/*.xml'
```

Bamboo YAML Specs allows for configuring test parsers with a simplified format. You can use one of the following configurations:

```yaml
testParsers:
  - mocha
  - junit
```
testParsers:
- type: mocha
  testResults: '**/mocha/*.json'
- type: junit
  testResults: '**/junit/*.xml'

testParsers:
- type: mocha
  testResults:
  - xxx.json
- type: junit
  testResults:
  - '**/test-reports/*.xml'
  - '**/custom-test-reports/*.xml'

.Bamboo Specs YAML format v6.5

Bamboo Specs YAML allows for a single plan definition in a single YAML file and accepts the following format:

---
project:
  key: DRAGON
plan:
  key: SLAYER
  name: Dragon Slayer Quest
# List of plan's stages
stages:
  # List of stage's jobs
  - jobs:
    # Scripts which are going to be executed within this job
    - scripts:
      - echo 'Going to kill the red dragon, watch me'
      - sleep 1
      - echo 'Nailed it'
    # Job's requirements. Only matching type 'exists' is supported
    - isDragonLazy
    # Job's artifacts. All artifacts are shared ones.
    - name: Red dragon's head
      path: dragon/red/head
    # Job's test parsers.
    testParsers:
      - type: mocha
        testResults: '**/mocha/*.json'
      - type: junit
        testResults: '**/junit/*.xml'
...
Bamboo YAML Specs allows for configuring test parsers with a simplified format. You can use one of the following configurations:

```yaml
  testParsers:
    - mocha
    - junit

  testParsers:
    - type: mocha
      testResults: '**/mocha/*.json'
    - type: junit
      testResults: '**/junit/*.xml'

  testParsers:
    - type: mocha
      testResults:
        - xxx.json
    - type: junit
      testResults:
        - '**/test-reports/*.xml'
        - '**/custom-test-reports/*.xml'
```

**Tutorial: Bamboo Specs YAML stored in Bitbucket Server**

This guide will show you how you can store Bamboo Specs in a Git repository on Bitbucket Server. This approach allows to automatically build and execute Bamboo Specs on every push you make to a Git repository.

### Before you begin
- Step 1: Create a Git repository in Bitbucket Sever and clone it locally
- Step 2: Create a linked repository in Bamboo
- Step 3: Enable processing of Bamboo Specs in your repository
- Step 4: Create Bamboo Specs project using Maven
- Step 5: Commit and push code changes to Bitbucket Server
- Step 6: Check if plan was created

### Related links
- Link to Bamboo Specs YAML reference

### Step 1: Create a Git repository in Bitbucket Sever and clone it locally

1. In Bitbucket Server, open the Projects page.
2. Click Create project.
3. Select Bamboo for project name and key and click Create project. You see that the project has no repositories.
4. Click Create repository.
5. Give your new repository the name tutorial, and click Create repository.

You've just created a new empty repository. Use the `git clone` command to create a clone on your computer. For example:
Step 2: Create a linked repository in Bamboo

1. Open Bamboo and go to
   > Linked repositories.
2. Click Add repository.
3. Select a Bitbucket Server / Stash repository type.
4. Choose a name for your repository.
5. From the Server drop-down, select your Bitbucket Server.
6. In the Web repository section, select the Bamboo / tutorial repository from the Web repository drop-down.
7. Click Save repository.

Your new repository is created and you can start using it in Bamboo.

Step 3: Enable processing of Bamboo Specs in your repository

By default Bamboo will not look for Bamboo Specs in the Git repository until your explicitly tell it to do so. Let's do it now:

1. Go to
   > Linked repositories.
2. Select your repository.
3. In the Bamboo Specs tab, enable Scan for Bamboo Specs.

In this tutorial we simply grant access to all projects in the Bamboo instance. You can fine-tune project access, see Enabling repository-stored Bamboo Specs how to do this.

Now, the Bamboo is ready to execute Bamboo Specs if it will be committed to the repository. Let's prepare some code.

Step 4: Create Bamboo Specs project using Maven

1. Go to the empty Git repository you cloned in step 1:
   ```
   cd tutorial
   ```

2. Use any of the templates we’ve prepared for your in Bamboo YAML Specs Reference or write YAML definition on your own with Bamboo Specs YAML format.

   It’s important to save your Bamboo Specs YAML definition in the bamboo-specs/bamboo.yaml file, under the repository root.
Step 5: Commit and push code changes to Bitbucket Server
1. Add created `bamboo-specs` directory to VCS and push changes to the server:

```bash
git add bamboo-specs
git commit -m "Initial commit of Bamboo Specs"
git push
```

As soon as you push your code changes to Bitbucket Server, Bamboo will get notified about a new commit available. Bamboo will checkout your repository, process it and create plan.

Execution of Bamboo Specs will create or update configuration of plans accordingly.

Step 6: Check if plan was created
1. Open your Bamboo instance.
2. From the header, select **Build > All build plans**.
3. Open the project and plan you've just created.

   All configuration options are disabled because entire plan configuration is now managed by Bamboo Specs from your Bitbucket repository.

4. Click **Run plan** to execute the build.
5. Find the "Hello World!" message in the logs.

Next steps

Here are some resources that can help you with writing your own Bamboo YAML Specs:

- Bamboo YAML Specs Reference

Tutorial: Bamboo Specs YAML stored in Bitbucket Server v6.3

This guide will show you how you can store Bamboo Specs in a Git repository on Bitbucket Server. This approach allows to automatically build and execute Bamboo Specs on every push you make to a Git repository.

- **Related links**
  - Link to Bamboo Specs YAML reference
Before you begin

- Make sure you have the following software installed:
  - Bamboo 6.3 or later
  - Bitbucket Server 4.0 or later
- Set up an application link between Bamboo and Bitbucket Server. See Integrating Bamboo with Bitbucket Server.

Step 1: Create a Git repository in Bitbucket Server and clone it locally

1. In Bitbucket Server, open the Projects page.
2. Click Create project.
3. Select Bamboo for project name and key and click Create project.
4. You see that the project has no repositories.
5. Click Create repository.
6. Give your new repository the name tutorial, and click Create repository.

You've just created a new empty repository. Use the git clone command to create a clone on your computer. For example:

```bash
git clone http://admin@localhost:7990/scm/bamboo/tutorial.git
```

Step 2: Enable processing of Bamboo Specs in your repository

By default Bamboo will not look for Bamboo Specs in the Git repository until you explicitly tell it to do so. Let's do it now:

1. Go to
   - Linked repositories.
2. Select your repository.
3. In the Bamboo Specs tab, enable Scan for Bamboo Specs.

In this tutorial we simply grant access to all projects in the Bamboo instance. You can fine-tune project access, see Enabling repository-stored Bamboo Specs how to do this.

Now, the Bamboo is ready to execute Bamboo Specs if it will be committed to the repository. Let's prepare some code.

Step 3: Create Bamboo Specs project using Maven

1. Go to the empty Git repository you cloned in step 1:

   ```bash
cd tutorial
   ```

2. Use any of the templates we've prepared for your in Bamboo YAML Specs Reference or write YAML definition on your own with Bamboo Specs YAML format.

   It's important to save your Bamboo Specs YAML definition in the ${repo-home}/bamboo-specs/bamboo.yml or bamboo-o.yaml file under the repository root.
Step 4: Create a new Project in Bamboo

1. Open Bamboo and go to Create > Create Project.
2. Fill in Project name.
3. If not auto-generated, fill in the Project Key – eg: DRAGON – this will be referenced in the YAML file
4. Click Save.

Step 4: Create a linked repository in Bamboo

1. Open Bamboo and go to
   ![Linked repositories](create.png)
2. Click Add repository.
3. Select a Bitbucket Server / Stash repository type.
4. Choose a name for your repository.
5. From the Server drop-down, select your Bitbucket Server.
6. In the Web repository section, select the Bamboo / tutorial repository from the Web repository drop-down.
7. Click Save repository.

Your new repository is created and you can start using it in Bamboo.

Step 5: Commit and push code changes to Bitbucket Server

1. Add created bamboo-specs directory to VCS and push changes to the server:

```bash
    git add bamboo-specs
    git commit -m "Initial commit of Bamboo Specs"
    git push
```

As soon as you push your code changes to Bitbucket Server, Bamboo will get notified about a new commit available. Bamboo will checkout your repository, process it and create plan. Execution of Bamboo Specs will create or update configuration of plans accordingly.

Step 6: Check if plan was created

1. Open your Bamboo instance.
2. From the header, select Build > All build plans.
3. Open the project and plan you've just created.

All configuration options are disabled because entire plan configuration is now managed by Bamboo Specs from your Bitbucket repository.
4. Click Run plan to execute the build.
5. Find the “Hello World!” message in the logs.

Next steps

Here are some resources that can help you with writing your own Bamboo YAML Specs:

- Bamboo YAML Specs Reference
- Tutorial: Bamboo Specs YAML stored in Bitbucket Server v6.4

This guide will show you how you can store Bamboo Specs in a Git repository on Bitbucket Server. This approach allows to automatically build and execute Bamboo Specs on every push you make to a Git repository.

Before you begin

- Make sure you have the following software installed:
  - Bamboo 6.3 or later
  - Bitbucket Server 4.0 or later
- Set up an application link between Bamboo and Bitbucket Server. See Integrating Bamboo with Bitbucket Server.

Step 1: Create a Git repository in Bitbucket Server and clone it locally

1. In Bitbucket Server, open the Projects page.
2. Click Create project.
3. Select Bamboo for project name and key and click Create project. You see that the project has no repositories.
4. Click Create repository.
5. Give your new repository the name tutorial, and click Create repository.

You've just created a new empty repository. Use the `git clone` command to create a clone on your computer. For example:

```
git clone http://admin@localhost:7990/scm/bamboo/tutorial.git
```

Step 2: Enable processing of Bamboo Specs in your repository

By default Bamboo will not look for Bamboo Specs in the Git repository until your explicitly tell it to do so. Let's do it now:

1. Go to
   - Linked repositories.
2. Select your repository.
3. In the Bamboo Specs tab, enable Scan for Bamboo Specs.

In this tutorial we simply grant access to all projects in the Bamboo instance. You can fine-tune project access, see Enabling repository-stored Bamboo Specs how to do this.

Now, the Bamboo is ready to execute Bamboo Specs if it will be committed to the repository. Let's prepare some code.
Step 3: Create Bamboo Specs project using Maven

1. Go to the empty Git repository you cloned in step 1:

   ```bash
cd tutorial
   ```

2. Use any of the templates we've prepared for your in Bamboo YAML Specs Reference or write YAML definition on your own with Bamboo Specs YAML format.

   It's important to save your Bamboo Specs YAML definition in the `${repo-home}/bamboo-specs/bamboo.yml` or `bamboo.yaml` file under the repository root.

   ```yaml
   project:
     key: DRAGON
   plan:
     key: SLAYER
     name: Dragon Slayer Quest
   stages:
   - jobs:
     - scripts:
       - echo 'Going to slay the red dragon, watch me'
       - sleep 1
       - echo 'Nailed it'
   ```

Step 4: Create a new Project in Bamboo

1. Open Bamboo and go to Create > Create Project.
2. Fill in Project name.
3. If not auto-generated, fill in the Project Key – eg: DRAGON – this will be referenced in the YAML file.
4. Click Save.

Step 5: Create a linked repository in Bamboo

1. Open Bamboo and go to

   > Linked repositories.
2. Click Add repository.
3. Select a Bitbucket Server / Stash repository type.
4. Choose a name for your repository.
5. From the Server drop-down, select your Bitbucket Server.
6. In the Web repository section, select the Bamboo / tutorial repository from the Web repository drop-down.
7. Click Save repository.

   Your new repository is created and you can start using it in Bamboo.

Step 6: Commit and push code changes to Bitbucket Server

1. Add created `bamboo-specs` directory to VCS and push changes to the server:

   ```bash
git add bamboo-specs
   git commit -m "Initial commit of Bamboo Specs"
git push
   ```

   As soon as you push your code changes to Bitbucket Server, Bamboo will get notified about a new commit available.
Bamboo will checkout your repository, process it and create a plan.
Execution of Bamboo Specs will create or update configuration of plans accordingly.

---

**Step 7: Check if plan was created**

1. Open your Bamboo instance.
2. From the header, select **Build > All build plans**.
3. Open the project and plan you’ve just created.

   > All configuration options are disabled because entire plan configuration is now managed by Bamboo Specs from your Bitbucket repository.

4. Click **Run plan** to execute the build.
5. Find the "Hello World!" message in the logs.

Bamboo Specs troubleshooting

We've gathered answers to most common problems with Bamboo Specs.

I committed Bamboo Specs but nothing happens

Make sure you pushed your code to the Bitbucket Server

It's trivial but it really happens.

Make sure that Bitbucket Server and Bamboo are connected using application link

1. Go to Application links

Make sure that Bamboo Specs processing is enabled in Bamboo

1. Go to Security settings > Repository Stored Specs security settings > Enable Repository Stored Specs

Make sure that Bamboo Specs is enabled for a repository you pushed to

1. Go to Linked repositories > `<your repository>`
2. In the Bamboo Specs tab, enable Scan for Bamboo Specs.

Make sure that Bamboo Specs has access to projects or deployment projects you want to modify

1. Go to Administration > Linked repositories.
2. Select your Bitbucket Server repository.
3. Select Enable all projects access or make sure that your build or deployments projects are listed in that section. See Enabling repository-stored Bamboo Specs.

Bamboo Specs compilation fails

In case compilation fails during the first execution of Bamboo Specs, no plans or deployment projects are created or updated. As a consequence, Bamboo is unable to associate the Bamboo Specs with any plan, so you will not find an error log in any of the existing plans.

In case compilation fails not at first time, you can find "Specs execution error" on the build results page for the related plans.

Note that in both cases a committer of the change will receive an email with details of the error.
Compilation may fail due to two reasons:

- **errors in the source code**
  
  Check out the repository on your computer and build it yourself ("mvn compile" or import into IDE) to locate the error. These are usually code typos, wrong project dependencies or an outdated parent pom version.

- **pom.xml has been sanitized by Bamboo**

  By default Bamboo Specs are executed with a default **pom.xml** file, i.e. it will not use **pom.xml** from your **bamboo-specs** project. For that reason, even if your **bamboo-specs** project compiles and runs correctly on your computer, it may fail in Bamboo.

  Make sure that:
  - it's sufficient to compile your project using **maven-resources-plugin** and **maven-compiler-plugin** only instead of using for instance extra plugins for code generation; don't rely on executing tests
  - it's sufficient to compile your project with **bamboo-specs** and **bamboo-specs-api** dependencies only - don't add extra dependencies
  - your **pom.xml** inherits from **com.atlassian.bamboo:bamboo-specs-parent**

  **Bamboo Specs compilation succeeds but log shows that not everything was built**

  Repository-stored Bamboo Specs feature requires your project in the **/bamboo-specs** directory will consist of only one Maven module. We do not support multi-module builds. So in case you put some Bamboo Specs classes in sub-modules of **bamboo-specs**, they simply won't be built.

  **Bamboo Specs fails to import configuration**

  Committer of the change will receive an email with details of the error. You can also look up for "Specs execution error" on the build results page of the related plan(s). Most typical reasons are:

  - **Insufficient permissions**
    
    Make sure that Bamboo Specs has access to projects or deployment projects you want to modify. It applies also to dependent projects, for instance:
    - child plans triggered after a build - see plan's dependencies section,
    - artifacts downloaded from a plan from another project.

  - **Validation errors**
    
    Bamboo validates your plan configuration for correctness. It reports an error if any constraint is violated, such as: invalid project key, reference to non-existing repository or plan etc.

### .Bamboo Specs troubleshooting v6.2

We've gathered answers to most common problems with Bamboo Specs.

**I committed Bamboo Specs but nothing happens**

It's trivial but it really happens.

- **Make sure that Bitbucket Server and Bamboo are connected using application link**
  
  1. Go to
     > Application links

- **Make sure that Bamboo Specs processing is enabled in Bamboo**
  
  1. Go to
     > Security settings > Repository Stored Specs security settings > Enable Repository Stored Specs

- **Make sure that Bamboo Specs is enabled for a repository you pushed to**
  
  1. Go to
     > Linked repositories > `<your repository>`

  2. In the Bamboo Specs tab, enable **Scan for Bamboo Specs**.
Make sure that Bamboo Specs has access to projects or deployment projects you want to modify

1. Go to **Administration > Linked repositories.**
2. Select your Bitbucket Server repository.
3. Select Enable all projects access or make sure that your build or deployments projects are listed in that section. See Enabling repository-stored Bamboo Specs.

**Bamboo Specs compilation fails**

In case compilation fails during the first execution of Bamboo Specs, no plans or deployment projects are created or updated. As a consequence, Bamboo is unable to associate the Bamboo Specs with any plan, so you will not find an error log in any of the existing plans.

In case compilation fails not at first time, you can find "Specs execution error" on the build results page for the related plans.

Note that in both cases a committer of the change will receive an email with details of the error.

Compilation may fail due to two reasons:

- **errors in the source code**
  
  Check out the repository on your computer and build it yourself ("mvn compile" or import into IDE) to locate the error. These are usually code typos, wrong project dependencies or an outdated parent pom version.

- **pom.xml has been sanitized by Bamboo**
  
  By default Bamboo Specs are executed with a default pom.xml file, i.e. it will not use pom.xml from your bamboo-specs project. For that reason, even if your bamboo-specs project compiles and runs correctly on your computer, it may fail in Bamboo.

  Make sure that:
  - it's sufficient to compile your project using maven-resources-plugin and maven-compiler-plugin only instead of using for instance extra plugins for code generation; don't rely on executing tests
  - it's sufficient to compile your project with bamboo-specs and bamboo-specs-api dependencies only - don't add extra dependencies
  - your pom.xml inherits from com.atlassian.bamboo:bamboo-specs-parent

**Bamboo Specs compilation succeeds but log shows that not everything was built**

Repository-stored Bamboo Specs feature requires your project in the/bamboo-specs directory will consist of only one Maven module. We do not support multi-module builds. So in case you put some Bamboo Specs classes in sub-modules of bamboo-specs, they simply won't be built.

**Bamboo Specs fails to import configuration**

Committer of the change will receive an email with details of the error. You can also look up for "Specs execution error" on the build results page of the related plan(s). Most typical reasons are:

  - artifacts downloaded from a plan from another project.

- **Validation errors**
  
  Bamboo validates your plan configuration for correctness. It reports an error if any constraint is violated, such as: invalid project key, reference to non-existing repository or plan etc.

.Bamboo Specs troubleshooting v6.5

We've gathered answers to most common problems with Bamboo Specs.

- **I committed Bamboo Specs but nothing happens**
  
  Make sure you pushed your code to the Bitbucket Server

  It's trivial but it really happens.

  **Make sure that Bitbucket Server and Bamboo are connected using application link**

  1. Go to

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
Make sure that Bamboo Specs processing is enabled in Bamboo

1. Go to
   
   Security settings > Repository Stored Specs security settings > Enable Repository Stored Specs

Make sure that Bamboo Specs is enabled for a repository you pushed to

1. Go to
   
   Linked repositories > <your repository>
   
   In the Bamboo Specs tab, enable Scan for Bamboo Specs.

Make sure that Bamboo Specs has access to projects or deployment projects you want to modify

1. Go to
   
   Administration > Linked repositories.
   
   2. Select your Bitbucket Server repository.
   
   3. Select Enable all projects access or make sure that your build or deployments projects are listed in that section. See Enabling repository-stored Bamboo Specs.

Bamboo Specs compilation fails

In case compilation fails during the first execution of Bamboo Specs, no plans or deployment projects are created or updated. As a consequence, Bamboo is unable to associate the Bamboo Specs with any plan, so you will not find an error log in any of the existing plans.

In case compilation fails not at first time, you can find "Specs execution error" on the build results page for the related plans.

Note that in both cases a committer of the change will receive an email with details of the error.

Compilation may fail due to two reasons:

- **errors in the source code**
  
  Check out the repository on your computer and build it yourself ("mvn compile" or import into IDE) to locate the error. These are usually code typos, wrong project dependencies or an outdated parent pom version.

- **pom.xml has been sanitized by Bamboo**
  
  By default Bamboo Specs are executed with a default pom.xml film, i.e. it will not use pom.xml from your bamboo-specs project. For that reason, even if your bamboo-specs project compiles and runs correctly on your computer, it may fail in Bamboo.

  Make sure that:
  
  - it's sufficient to compile your project using maven-resources-plugin and maven-compiler-plugin only instead of using for instance extra plugins for code generation; don't rely on executing tests
  - it's sufficient to compile your project with bamboo-specs and bamboo-specs-api dependencies only - don't add extra dependencies
  - your pom.xml inherits from com.atlassian.bamboo:bamboo-specs-parent

Bamboo Specs compilation succeeds but log shows that not everything was built

Repository-stored Bamboo Specs feature requires your project in the/bamboo-specs directory will consist of only one Maven module. We do not support multi-module builds. So in case you put some Bamboo Specs classes in sub-modules of bamboo-specs, they simply won't be built.

Bamboo Specs fails to import configuration

Committer of the change will receive an email with details of the error. You can also look up for "Specs execution error" on the build results page of the related plan(s). Most typical reasons are:

**Insufficient permissions**

Make sure that Bamboo Specs has access to projects or deployment projects you want to modify. It applies also to dependent projects, for instance:

- child plans triggered after a build - see plan's dependencies section,
- artifacts downloaded from a plan from another project.

**Validation errors**
Bamboo validates your plan configuration for correctness. It reports an error if any constraint is violated, such as: invalid project key, reference to non-existing repository or plan etc.

The repository in which you defined a plan has no permissions to access a project
1. Go to <Coghweel> Linked repositories.
2. Select your repository.
3. Click on the Bamboo Specs tab.
4. Copy the webhook URL.
5. In therepositoryyou want to use for storing Bamboo Specs, go to your repository settings.
6. Find webhook-specific configuration.
7. Paste in the URL Bamboo provided you with.

A webhook that allows your repository to communicate with Bamboo is not set up
1. In the top navigation bar, click Projects.
2. Select your project.
3. Click Project settings > Bamboo Specs repositories.
4. Select your repository and click Add.
5. Go to settings the repository you want to use for storing Bamboo Specs.
6. Find webhook-specific configuration.
7. Paste in the URL Bamboo provided you with.

Bamboo Specs - supported scenarios

Bamboo Specs typical use case scenarios:
- Migration of existing plans that were created via the Bamboo UI
- New plan configurations created with Bamboo Specs directly and that contain little if any glue code.
- New plan configurations created with Bamboo Specs, or existing plans that are migrated to Specs, which contain a significant amount of glue code which is complex.

What Atlassian support can help you out with:
- Migration of existing plans that were created using the UI to Bamboo Specs with minimal glue code, preferably with minor or any) changes to the code that is provided by the View Plan as Specs feature
- New plan configurations that are created with Bamboo Specs which contain a minimal amount of glue code, similar to what is generated by View Plan as Specs.

Bamboo Specs projects that contain a large amount of complex glue code fall outside supported scenarios. For such cases, we recommend starting from simple Bamboo Specs, preferably produced by the View Plan as Specs with a minimal amount of glue code. Then gradually add the complex code and perform as many intermediary tests as possible to be able to detect errors sooner rather than later.

Below is a list of Atlassian validated Bamboo Specs code:
- code generated by View Plan as Bamboo Specs from within the Bamboo UI
- code from the official documented tutorials
- sample code snippets described in the latest Bamboo specs reference documentation, which show the use of the API.

Why configuration as code?

Configuration as code is now available in Bamboo! We called this feature Bamboo Specs. Learn more about this feature that lets you store build plans configuration as code,
- Why configuration as code?
- What’s in the package?
  - Bamboo goodies
  - High-level language for configuration
  -Configuration in a language of your choice
  - Docs and more docs
- OK, I’m sold. Where do I start?
Consider storing your build plan configuration as code for easier automation, change tracking, validation, and much more. You can read about the details in What is configuration as code?.

What's in the package?

✓ Bamboo goodies

- Bamboo Specs library with an API for writing configuration as code
- Bamboo Specs Runner Maven plugin for easier plan deployments

✓ High-level language for configuration

YAML can get the job done, but we know that enterprise users need something much more powerful. That's why we decided to use a simple Java-based plan description language:

- Enjoy highlighting, syntax checks, and code autocompletion.
- Validate when you compile and run offline tests.
- Use high-level language features like modularization or libraries.

If you're not familiar with Java, don't worry. Our onboarding process will bootstrap you directly into a working environment and we have made sure that the plan definitions will be familiar to users of other languages such as Python, C++ or C#. You can read about the details in Configuration as code in Bamboo.

✓ Configuration in a language of your choice

The Bamboo Specs library is written in Java. It means that you can write your code in any high-level JVM language that interoperates with Java, for example Groovy, Scala, or Kotlin.

✓ Docs and more docs

We're still working on our documentation, but progress is more important than perfection, so we're sharing the first versions with you.

- Bamboo Specs Reference
  Concepts explained with examples. We really like this one, check it out!

- Bamboo Specs API reference
  Our API. Documented

- Best practices
  Because we already have some recommendations!

OK, I'm sold. Where do I start?

Easy. We've prepared some short tutorials for you.

Start with Java  |  Start with YAML

.Bamboo Specs v6.4

Configuration as code is now available in Bamboo! We called this feature Bamboo Specs. Learn more about this feature that lets you store build plans configuration as code.

- Why configuration as code?
• What's in the package?
  • Bamboo goodies
  • High-level language for configuration
  • Configuration in a language of your choice
  • Docs and more docs
  • OK, I'm sold. Where do I start?

Why configuration as code?
Consider storing your build plan configuration as code for easier automation, change tracking, validation, and much more. You can read about the details in What is configuration as code?

What's in the package?

✔️ Bamboo goodies
  • Bamboo Specs library with an API for writing configuration as code
  • Bamboo Specs Runner Maven plugin for easier plan deployments

✔️ High-level language for configuration

YAML can get the job done, but we know that enterprise users need something much more powerful. That's why we decided to use a simple Java-based plan description language:

• Enjoy highlighting, syntax checks, and code autocompletion.
• Validate when you compile and run offline tests.
• Use high-level language features like modularization or libraries.

If you're not familiar with Java, don't worry. Our onboarding process will bootstrap you directly into a working environment and we have made sure that the plan definitions will be familiar to users of other languages such as Python, C++ or C#.

✔️ Configuration in a language of your choice

The Bamboo Specs library is written in Java. It means that you can write your code in any high-level JVM language that interoperates with Java, for example Groovy, Scala, or Kotlin.

✔️ Docs and more docs

We're still working on our documentation, but progress is more important than perfection, so we're sharing the first versions with you.

Bamboo Specs Reference
Concepts explained with examples. We really like this one, check it out!

Bamboo Specs API reference
Our API. Documented

😊 Best practices
Because we already have some recommendations!

Supported scenarios
Make the best use out of Bamboo Specs and our Support.

OK, I'm sold. Where do I start?

Easy. We've prepared some short tutorials for you.

Start with Java | Start with YAML

Quick links

• What is configuration as code?
Bamboo releases

The following pages can be found in the latest documentation for Bamboo:

- the Bamboo upgrade guide
- the Bamboo security advisories
- the End of support announcements for Bamboo
- the full release notes for every Bamboo release.

You can get automated notifications about major Bamboo releases by subscribing to the Atlassian blog.

The list below is a summary of the Bamboo releases. The changelogs included in the release notes (linked below) have details of the related bug-fix releases.

**Bamboo 6.7**

October 2018

- Parsing build warnings
- New VCS tasks
- Welcome IPv6
- Bamboo Docker images
- Deployment project configuration now in audit log

For more information, see [Bamboo 6.7 Release Notes](#).

**Bamboo 6.6**

June 2018

- Embedded Crowd

For more information, see [Bamboo 6.6 Release Notes](#).

**Bamboo 6.5**

24 April 2018

- Bamboo Specs run on new repos
- Bamboo gets a new logo

For more information, see [Bamboo 6.5 Release Notes](#).

**Bamboo 6.4**

21 February 2018

- Docker Runner
- Force-stop hanging builds

For more information, see [Bamboo 6.4 Release Notes](#).

**Bamboo 6.3**

20 December 2017

- Bamboo YAML Specs
- New repository-stored Bamboo Specs protection

For more information, see [Bamboo 6.3 Release Notes](#).
• Branching with multiple repositories
• Cleaning up permissions dependencies
• Nested variables

For more information, see Bamboo 6.3 Release Notes.

Bamboo 6.2

28 September 2017
• Changes to permissions
• Artifact handler
• Repository-stored Bamboo Specs
• Support for Bitbucket Server Smart Mirroring
• Bamboo YAML

For more information, see Bamboo 6.2 Release Notes.

Bamboo 6.1

20 July 2017
• Improvements to Bamboo Specs for plans
• Bamboo Specs for Deployments

For more information, see Bamboo 6.1 Release Notes.

Bamboo 6.0

26 April 2017
• Configuration as Code
• SQL Server JDBC driver update
• Pull request in the branch status page
• Fastlane and Xcode support

Fore more information, see Bamboo 6.0 Release Notes.

Bamboo 5.15

14 February 2017
• Git LFS support
• System-wide encryption
• Improvements to the Branch Status page
• Spring Scanner 2 support

For more information, see Bamboo 5.15 Release Notes.

Bamboo 5.14

27 October 2016
• Platform upgrades
• New Branch status page
• Build plans and deployment projects in YAML (beta)
• Override of repository settings for plan branches
• Enhancements for Subversion repository configuration
• New API for VCS repositories
• Bug fixes

For more information, see Bamboo 5.14 Release Notes.

Bamboo 5.13

24 August 2016
• Platform upgrades
• Deployment requirements
• SSH support for Bitbucket Cloud
• Improvements for the script task
• Absolute paths for artifacts
• Bug fixes
• API changes

For more information, see Bamboo 5.13 Release Notes.

Bamboo 5.12
24 May 2016
• Platform upgrades
• Quick Filters
• User deactivation directly from Bamboo
• Bug fixes

For more information, see Bamboo 5.12 Release Notes.

Bamboo 5.11
26 April 2016
• Platform upgrades
• Application Links upgrade to version 5.0.7
• Bamboo Instance Health check
• New Create repository permission
• REST API deployment triggers

For more information, see Bamboo 5.11 Release Notes.

Bamboo 5.10
19 January 2016
• Platform upgrades
• Bamboo build status for Bitbucket

For more information, see Bamboo 5.10 Release Notes.

Bamboo 5.9
11 June 2015
• Improved automatic branch management
• Improved Docker task customization
• AWS Code Deploy task for Bamboo
• Easier shared credentials management
• Future changes to on-disk directory layout: plan directory information REST API
• Bamboo Clover Plugin improvements

Read more in Bamboo 5.9 Release Notes.

For more information, see Bamboo upgrade guide.

Bamboo 5.8
17 March 2015
• Docker task for builds and deployments
• Improved integration with AWS
• Bamboo analytics added
• Support for Java 8
• Support for Java 7 is deprecated
• Support for Microsoft SQL Server 2005 and 2008 is deprecated
• Support for MySQL 5.1 is deprecated
• Support for PostgreSQL 8 is deprecated

Read more in the Bamboo 5.8 Release Notes.

See the Bamboo upgrade guide.

Bamboo 5.7
11 November 2014
• Control storage demands of deployment artifacts
• Take charge of build and release variables
• Manage remote Bamboo agents with Docker
• Use Bamboo with Node.js projects
• New Bamboo search tool for projects and plans
• Bamboo now supports Microsoft SQL Server 2012
• Support for Java 6 is deprecated
• Legacy Stash integration features removed

Read more in the Bamboo 5.7 Release Notes.

See the Bamboo upgrade guide.

Bamboo 5.6
29 July 2014

• Improved Stash integration:
  • Bamboo builds are triggered by Stash repo events
  • Bamboo plan branches update when branches are created or deleted in Stash
  • Bamboo build status is notified automatically to Stash
• Dedicated agents
• Clone deployment projects
• Deployments now appear in the activity streams for agents and builds
• Build queue improvements
• Project name is now editable
• The legacy Stash notifications and web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7.

Read more in the Bamboo 5.6 Release Notes.

See the Bamboo upgrade guide.

Bamboo 5.5
28 April 2014

• Improved Stash integration
• Share repositories renamed to 'linked' repositories
• Stash legacy web repositories deprecated
• Bamboo menu layout change
• Subversion 1.8 is now supported
• Tomcat 5.5 and 6.0 are no longer supported.
• Internet Explorer 8 is no longer supported.

Read more in the Bamboo 5.5 release notes.

See the Bamboo upgrade guide.

Bamboo 5.4
11 February 2014

• Administration access navigation change
• Deployment workflow
• Deployment dashboard
• Reliability and stability
• Tomcat 5.5 and 6.0 deprecated.

Read more in the Bamboo 5.4 release notes.

See the Bamboo upgrade guide.

Bamboo 5.3
11 December 2013

• XSRF protection
• Deployment preview

Read more in the Bamboo 5.3 release notes.

See the Bamboo upgrade guide.

Bamboo 5.2
15 October 2013
- Branch deployments
- Advanced Gravatar support
- Branch checking interval editing

Read more in the Bamboo 5.2 release notes.
See the Bamboo upgrade guide.

Bamboo 5.1
13 September 2013
- Jira issue deployment reporting

Read more in the Bamboo 5.1 release notes.
See the Bamboo upgrade guide.

Bamboo 5.0
28 August 2013
- Deployment projects and environments
- Release versioning

Read more in the Bamboo 5.0 release notes.
See the Bamboo upgrade guide.

Bamboo 4.4
29 January 2013
- Jenkins importer
- Enhanced performance
- TestNG reports parser
- Selective task running
- Quick build number copying
- Server pausing

Read more in the Bamboo 4.4 release notes.
See the Bamboo upgrade guide.

Bamboo 4.3
30 October 2012
- Simple deployments to Tomcat
- Deploy to the Cloud with Heroku
- Upload files using SCP
- Build from any revision
- Runtime variables for Manual Stages
- Rebuild with one click
- Multiple build Triggers
- Build dependencies after all Stages
- Automatic dependencies for Maven 3
- Dashboard filtering
- Amazon Virtual Private Cloud for Elastic Bamboo
- Wallboard for Branches

Read more in the Bamboo 4.3 release notes.
See the Bamboo upgrade guide.

Bamboo 4.2
21 August 2012
- Notifications, build strategies and dependencies for plan branches
- Automatic linking of Jira issues to feature branches
- Bamboo build artifacts are linked from Jira issues
- Git support in the Bamboo Bitbucket connector
- Subversion 1.7 support
- UX improvements
- Mercurial commit isolation

Read more in the Bamboo 4.2 release notes.

See the Bamboo upgrade guide.

**Bamboo 4.1**

29 May 2012

- Get builds fixed faster with responsibilities
- Take action with Jira issue creation
- Get your team communicating with Hipchat notifications
- Welcome to the family, Stash!

Read more in the Bamboo 4.1 release notes.

See the Bamboo upgrade guide.

**Bamboo 4.0**

27 March 2012

- Automatically Build Branches
- Automatically Merge Branches using Gatekeeper and Branch Updater
- Manage Build Failures by Quarantining Intermittent Tests
- Fresh New User Experience

Read more in the Bamboo 4.0 release notes.

See the Bamboo upgrade guide.

**Bamboo 3.4**

14 December 2011

- Git Submodule Support
- Shared Repositories
- Agent Security Improvements
- New Email Templates
- Elastic Bamboo support for Microsoft Windows®

Read more in the Bamboo 3.4 release notes.

See the Bamboo upgrade guide.

**Bamboo 3.3**

11 October 2011

- Multiple Source Repositories
- Reload-able Plugins
- Source Repository User Aliases
- Automatic Agent Upgrades
- Fast, history-friendly tabbed navigation
- Commit Centric View

Read more in the Bamboo 3.3 release notes.

See the Bamboo upgrade guide.

**Bamboo 3.2**

26 July 2011

- Release Management
- Manual Stages
- Rerunning a Failed Stage
- Plan Filters on the Dashboard and Wallboard
- User Management via Jira
- Improved Application Linking
Bamboo 3.1
10 May 2011

- Tasks
- Parameterized Builds
- .Net Support
- Bitbucket Support
- GitHub Support
- New Plugin Manager
- Support for Amazon EC2 Spot Instances
- Gravatar Support
- Improved Windows process handling

Read more in the Bamboo 3.1 release notes.

See the Bamboo upgrade guide.

Bamboo 3.0
16 February 2011

- Artifact Sharing
- Git Support
- User Interface Overhaul — Redesigned Plan Summary, Job Summary and Build Results. New look and feel.
- Scheduled Repository Polling
- Configuration Changes Captured in Audit Logs

Read more in the Bamboo 3.0 release notes.

See the Bamboo upgrade guide.

Bamboo 2.7
9 Nov 2010

- Build Stages — Map Your Build Process, Parallel Builds, Enhanced Plan Structure
- Simplified Plan Creation
- Concurrent Builds
- Mercurial Support
- Improved Wallboards
- New Plan and Job Configuration Summaries
- Recent History on Plan and Job Summaries
- Other User Interface Enhancements — New Breadcrumb Trail, Build Histories, Improved Build Result Summary Tabs

Read more in the Bamboo 2.7 release notes.

See the Bamboo upgrade guide.

Bamboo 2.6
1 June 2010

- Support for up to 100 Remote Agents
- Revamped Dashboard Pages and Other Usability Enhancements
- Performance and Security Improvements
- Automatically Managed Elastic Instances
- Grails Integration

Read more in the Bamboo 2.6 release notes.

See the Bamboo upgrade guide.

Bamboo 2.5
4 January 2010

- Maven Dependency Management
- Plan Import from a pom.xml
- Additional Bulk Actions
• Streamlined Plan Creation
• Express Setup Wizard

Read more in the Bamboo 2.5 release notes.
See the Bamboo upgrade guide.

Bamboo 2.4
6 October 2009
• Bamboo Gadgets in Jira
• Clover Enhancements
• REST Improvements
• Runtime Log4j Configuration

Read more in the Bamboo 2.4 release notes.
See the Bamboo upgrade guide.

Bamboo 2.3
6 August 2009
• Dependency Blocking Strategies
• New Build Notifications and Queue Reordering
• Bulk Actions
• Multiple Elastic Images
• Elastic Instance Scheduling
• PHPUnit Builder
• Bamboo REST APIs
• Plugins Changes

Read more in the Bamboo 2.3 release notes.
See the Bamboo upgrade guide.

Bamboo 2.2
9 March 2009
• Elastic Bamboo
• Customizable Email Templates
• Build Comment Notification Event
• Hanging Build Detection Event
• Faster Artifact Transfer
• Dependent Builds
• Agent Improvements

Read more in the Bamboo 2.2 release notes.
See the Bamboo upgrade guide.

Bamboo 2.1
5 August 2008
• Link Issues and Builds
• Specify the Issues that are Fixed by a Build
• Track the Builds for your Projects and Versions
• View Issues under Development
• Post Change Detection Plugin Point

Read more in the Bamboo 2.1 release notes.
See the Bamboo upgrade guide.

Bamboo 2.0
14 April 2008
• Distributed builds
• Capability matching
• Memory usage improvements
• Parallel VCS updates and checkouts
• Ability to force a ‘clean build’
• Quiet Period functionality supported for Subversion & Perforce
• Bamboo Plugin for Confluence
• Support for Oracle and MS SQL Server databases
• Status Summary screens

Read more in the Bamboo 2.0 release notes.

See the Bamboo upgrade guide.

Bamboo 1.2

09 July 2007

• Permissions (global and plan-based)
• External database support
• Perforce triggering support
• Scheduled backups
• New Bundled NAnt plugin

Read more in the Bamboo 1.2 release notes.

See the Bamboo upgrade guide.

Bamboo 1.1

07 May 2007

• Advanced notifications - rules, triggers, preferences, dynamic recipients
• Build Metadata - pass them to your build, global variables, view them
• File Trigger Inclusions/Exclusions
• More pluggability
• Improved Maven 2 error log parsing
• LDAP and external user management support
• Dashboard loading has been improved

Read more in the Bamboo 1.1 release notes.

See the Bamboo upgrade guide.

Bamboo 1.0

20 February 2007

• All Plans tab

Read more in the Bamboo 1.0 release notes.

See the Bamboo upgrade guide.

Bamboo security advisories

As a distributed application, Bamboo’s application-level security is important. This document contains links to version-specific security advisories and related documents for the Bamboo application.

This document is intended to provide information to system administrators about the security of the Bamboo application. It does not describe Bamboo’s internal security model – user management and permissions – except as it relates to the overall application security.

Finding and reporting a security vulnerability

Atlassian’s channel for reporting security issues is detailed in How to Report a Security Issue.

Publication of Bamboo security advisories

Atlassian’s approach to publishing security advisories is detailed in Security Advisory Publishing Policy.

You can subscribe to email alerts or modify the settings according to the guidelines in Subscribing to security advisories below.
Severity levels

Atlassian’s scale for measuring security issues is detailed in Severity Levels for Security Issues.

Our patch policy

Atlassian’s approach to releasing patches is detailed in our Security Patch Policy.

Subscribing to security advisories

You can configure Atlassian email notifications in your MyAtlassian account. We especially recommend subscribing to email alerts if you're the primary contact for a product.

1. Go to MyAtlassian account. Sign in to your account or create a new one, it's super quick.
2. Once you signed in, click Email preferences in the menu at the very top of the page.
3. In Email preferences, scroll down to Alerts.
4. Select products for which you would like to receive alerts about security advisories, maintenance notifications, and pricing updates.
5. Select the format in which we'll send you the emails. You can choose between HTML and text.
6. Click Update my email preferences to save the new configuration.

Security advisories

Bamboo releases v6.2

The following pages can be found in the latest documentation for Bamboo:

- the Bamboo upgrade guide
- the Bamboo security advisories
- the End of support announcements for Bamboo
- the full release notes for every Bamboo release.

You can get automated notifications about major Bamboo releases by subscribing to the Atlassian blog.

The list below is a summary of the Bamboo releases. The changelogs included in the release notes (linked below) have details of the related bug-fix releases.

Bamboo 6.7

October 2018

- Parsing build warnings
- New VCS tasks
- Welcome IPv6
- Bamboo Docker images
- Deployment project configuration now in audit log

For more information, see Bamboo 6.7 Release Notes

Bamboo 6.6

June 2018

- Embedded Crowd

For more information, see Bamboo 6.6 Release Notes.

Bamboo 6.5

24 April 2018

- Bamboo Specs run on new repos
- Bamboo gets a new logo

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
For more information, see Bamboo 6.5 Release Notes.

**Bamboo 6.4**

21 February 2018

- Docker Runner
- Force-stop hanging builds

For more information, see Bamboo 6.4 Release Notes.

**Bamboo 6.3**

20 December 2017

- Bamboo YAML Specs
- New repository-stored Bamboo Specs protection
- Branching with multiple repositories
- Cleaning up permissions dependencies
- Nested variables

For more information, see Bamboo 6.3 Release Notes.

**Bamboo 6.2**

28 September 2017

- Changes to permissions
- Artifact handler
- Repository-stored Bamboo Specs
- Support for Bitbucket Server Smart Mirroring
- Bamboo YAML

For more information, see Bamboo 6.2 Release Notes.

**Bamboo 6.1**

20 July 2017

- Improvements to Bamboo Specs for plans
- Bamboo Specs for Deployments

For more information, see Bamboo 6.1 Release Notes.

**Bamboo 6.0**

26 April 2017

- Configuration as Code
- SQL Server JDBC driver update
- Pull request in the branch status page
- Fastlane and Xcode support

For more information, see Bamboo 6.0 Release Notes.

**Bamboo 5.15**

14 February 2017

- Git LFS support
- System-wide encryption
- Improvements to the Branch Status page
- Spring Scanner 2 support

For more information, see Bamboo 5.15 Release Notes.

**Bamboo 5.14**
27 October 2016

- Platform upgrades
- New Branch status page
- Build plans and deployment projects in YAML (beta)
- Override of repository settings for plan branches
- Enhancements for Subversion repository configuration
- New API for VCS repositories
- Bug fixes

For more information, see Bamboo 5.14 Release Notes.

Bamboo 5.13

24 August 2016

- Platform upgrades
- Deployment requirements
- SSH support for Bitbucket Cloud
- Improvements for the script task
- Absolute paths for artifacts
- Bug fixes
- API changes

For more information, see Bamboo 5.13 Release Notes.

Bamboo 5.12

24 May 2016

- Platform upgrades
- Quick Filters
- User deactivation directly from Bamboo
- Bug fixes

For more information, see Bamboo 5.12 Release Notes.

Bamboo 5.11

26 April 2016

- Platform upgrades
- Application Links upgrade to version 5.0.7
- Bamboo Instance Health check
- New Create repository permission
- REST API deployment triggers

For more information, see Bamboo 5.11 Release Notes.

Bamboo 5.10

19 January 2016

- Platform upgrades
- Bamboo build status for Bitbucket

For more information, see Bamboo 5.10 Release Notes.

Bamboo 5.9

11 June 2015

- Improved automatic branch management
- Improved Docker task customization
- AWS Code Deploy task for Bamboo
- Easier shared credentials management
- Future changes to on-disk directory layout: plan directory information REST API
- Bamboo Clover Plugin improvements

Read more in Bamboo 5.9 Release Notes.
For more information, see Bamboo upgrade guide.

**Bamboo 5.8**

17 March 2015

- Docker task for builds and deployments
- Improved integration with AWS
- Bamboo analytics added
- Support for Java 8
- Support for Java 7 is deprecated
- Support for Microsoft SQL Server 2005 and 2008 is deprecated
- Support for MySQL 5.1 is deprecated
- Support for PostgreSQL 8 is deprecated

Read more in the Bamboo 5.8 Release Notes.

See the Bamboo upgrade guide.

**Bamboo 5.7**

11 November 2014

- Control storage demands of deployment artifacts
- Take charge of build and release variables
- Manage remote Bamboo agents with Docker
- Use Bamboo with Node.js projects
- New Bamboo search tool for projects and plans
- Bamboo now supports Microsoft SQL Server 2012
- Support for Java 6 is deprecated
- Legacy Stash integration features removed

Read more in the Bamboo 5.7 Release Notes.

See the Bamboo upgrade guide.

**Bamboo 5.6**

29 July 2014

- Improved Stash integration:
  - Bamboo builds are triggered by Stash repo events
  - Bamboo plan branches update when branches are created or deleted in Stash
  - Bamboo build status is notified automatically to Stash
- Dedicated agents
- Clone deployment projects
- Deployments now appear in the activity streams for agents and builds
- Build queue improvements
- Project name is now editable
- The legacy Stash notifications and web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7.

Read more in the Bamboo 5.6 Release Notes.

See the Bamboo upgrade guide.

**Bamboo 5.5**

28 April 2014

- Improved Stash integration
- Share repositories renamed to 'linked' repositories
- Stash legacy web repositories deprecated
- Bamboo menu layout change
- Subversion 1.8 is now supported
- Tomcat 5.5 and 6.0 are no longer supported.
- Internet Explorer 8 is no longer supported.

Read more in the Bamboo 5.5 release notes.

See the Bamboo upgrade guide.

**Bamboo 5.4**
11 February 2014

- Administration access navigation change
- Deployment workflow
- Deployment dashboard
- Reliability and stability
- Tomcat 5.5 and 6.0 deprecated.

Read more in the Bamboo 5.4 release notes.

See the Bamboo upgrade guide.

Bamboo 5.3

11 December 2013

- XSRF protection
- Deployment preview

Read more in the Bamboo 5.3 release notes.

See the Bamboo upgrade guide.

Bamboo 5.2

15 October 2013

- Branch deployments
- Advanced Gravatar support
- Branch checking interval editing

Read more in the Bamboo 5.2 release notes.

See the Bamboo upgrade guide.

Bamboo 5.1

13 September 2013

- Jira issue deployment reporting

Read more in the Bamboo 5.1 release notes.

See the Bamboo upgrade guide.

Bamboo 5.0

28 August 2013

- Deployment projects and environments
- Release versioning

Read more in the Bamboo 5.0 release notes.

See the Bamboo upgrade guide.

Bamboo 4.4

29 January 2013

- Jenkins importer
- Enhanced performance
- TestNG reports parser
- Selective task running
- Quick build number copying
- Server pausing

Read more in the Bamboo 4.4 release notes.

See the Bamboo upgrade guide.

Bamboo 4.3
30 October 2012

- Simple deployments to Tomcat
- Deploy to the Cloud with Heroku
- Upload files using SCP
- Build from any revision
- Runtime variables for Manual Stages
- Rebuild with one click
- Multiple build Triggers
- Build dependencies after all Stages
- Automatic dependencies for Maven 3
- Dashboard filtering
- Amazon Virtual Private Cloud for Elastic Bamboo
- Wallboard for Branches

Read more in the Bamboo 4.3 release notes.
See the Bamboo upgrade guide.

Bamboo 4.2

21 August 2012

- Notifications, build strategies and dependencies for plan branches
- Automatic linking of Jira issues to feature branches
- Bamboo build artifacts are linked from Jira issues
- Git support in the Bamboo Bitbucket connector
- Subversion 1.7 support
- UX improvements
- Mercurial commit isolation

Read more in the Bamboo 4.2 release notes.
See the Bamboo upgrade guide.

Bamboo 4.1

29 May 2012

- Get builds fixed faster with responsibilities
- Take action with Jira issue creation
- Get your team communicating with Hipchat notifications
- Welcome to the family, Stash!

Read more in the Bamboo 4.1 release notes.
See the Bamboo upgrade guide.

Bamboo 4.0

27 March 2012

- Automatically Build Branches
- Automatically Merge Branches using Gatekeeper and Branch Updater
- Manage Build Failures by Quarantining Intermittent Tests
- Fresh New User Experience

Read more in the Bamboo 4.0 release notes.
See the Bamboo upgrade guide.

Bamboo 3.4

14 December 2011

- Git Submodule Support
- Shared Repositories
- Agent Security Improvements
- New Email Templates
- Elastic Bamboo support for Microsoft Windows®

Read more in the Bamboo 3.4 release notes.
See the Bamboo upgrade guide.
Bamboo 3.3

11 October 2011

- Multiple Source Repositories
- Reload-able Plugins
- Source Repository User Aliases
- Automatic Agent Upgrades
- Fast, history-friendly tabbed navigation
- Commit Centric View

Read more in the Bamboo 3.3 release notes.

See the Bamboo upgrade guide.

Bamboo 3.2

26 July 2011

- Release Management
- Manual Stages
- Rerunning a Failed Stage
- Plan Filters on the Dashboard and Wallboard
- User Management via Jira
- Improved Application Linking

Read more in the Bamboo 3.2 release notes.

See the Bamboo upgrade guide.

Bamboo 3.1

10 May 2011

- Tasks
- Parameterized Builds
- .Net Support
- Bitbucket Support
- GitHub Support
- New Plugin Manager
- Support for Amazon EC2 Spot Instances
- Gravatar Support
- Improved Windows process handling

Read more in the Bamboo 3.1 release notes.

See the Bamboo upgrade guide.

Bamboo 3.0

16 February 2011

- Artifact Sharing
- Git Support
- User Interface Overhaul — Redesigned Plan Summary, Job Summary and Build Results. New look and feel.
- Scheduled Repository Polling
- Configuration Changes Captured in Audit Logs

Read more in the Bamboo 3.0 release notes.

See the Bamboo upgrade guide.

Bamboo 2.7

9 Nov 2010

- Build Stages — Map Your Build Process, Parallel Builds, Enhanced Plan Structure
- Simplified Plan Creation
- Concurrent Builds
- Mercurial Support
- Improved Wallboards
- New Plan and Job Configuration Summaries
Recent History on Plan and Job Summaries
Other User Interface Enhancements — New Breadcrumb Trail, Build Histories, Improved Build Result Summary Tabs

Read more in the Bamboo 2.7 release notes.
See the Bamboo upgrade guide.

Bamboo 2.6
1 June 2010
- Support for up to 100 Remote Agents
- Revamped Dashboard Pages and Other Usability Enhancements
- Performance and Security Improvements
- Automatically Managed Elastic Instances
- Grails Integration

Read more in the Bamboo 2.6 release notes.
See the Bamboo upgrade guide.

Bamboo 2.5
4 January 2010
- Maven Dependency Management
- Plan Import from a pom.xml
- Additional Bulk Actions
- Streamlined Plan Creation
- Express Setup Wizard

Read more in the Bamboo 2.5 release notes.
See the Bamboo upgrade guide.

Bamboo 2.4
6 October 2009
- Bamboo Gadgets in Jira
- Clover Enhancements
- REST Improvements
- Runtime Log4j Configuration

Read more in the Bamboo 2.4 release notes.
See the Bamboo upgrade guide.

Bamboo 2.3
6 August 2009
- Dependency Blocking Strategies
- New Build Notifications and Queue Reordering
- Bulk Actions
- Multiple Elastic Images
- Elastic Instance Scheduling
- PHPUnit Builder
- Bamboo REST APIs
- Plugins Changes

Read more in the Bamboo 2.3 release notes.
See the Bamboo upgrade guide.

Bamboo 2.2
9 March 2009
- Elastic Bamboo
- Customizable Email Templates
- Build Comment Notification Event
- Hanging Build Detection Event

Created by Atlassian in 2018. Licensed under a Creative Commons Attribution 2.5 Australia License.
• Faster Artifact Transfer
• Dependent Builds
• Agent Improvements

Read more in the Bamboo 2.2 release notes.

See the Bamboo upgrade guide.

Bamboo 2.1

5 August 2008

• Link Issues and Builds
• Specify the Issues that are Fixed by a Build
• Track the Builds for your Projects and Versions
• View Issues under Development
• Post Change Detection Plugin Point

Read more in the Bamboo 2.1 release notes.

See the Bamboo upgrade guide.

Bamboo 2.0

14 April 2008

• Distributed builds
• Capability matching
• Memory usage improvements
• Parallel VCS updates and checkouts
• Ability to force a ‘clean build’
• Quiet Period functionality supported for Subversion & Perforce
• Bamboo Plugin for Confluence
• Support for Oracle and MS SQL Server databases
• Status Summary screens

Read more in the Bamboo 2.0 release notes.

See the Bamboo upgrade guide.

Bamboo 1.2

09 July 2007

• Permissions (global and plan-based)
• External database support
• Perforce triggering support
• Scheduled backups
• New Bundled NAnt plugin

Read more in the Bamboo 1.2 release notes.

See the Bamboo upgrade guide.

Bamboo 1.1

07 May 2007

• Advanced notifications - rules, triggers, preferences, dynamic recipients
• Build Metadata - pass them to your build, global variables, view them
• File Trigger Inclusions/Exclusions
• More pluggability
• Improved Maven 2 error log parsing
• LDAP and external user management support
• Dashboard loading has been improved

Read more in the Bamboo 1.1 release notes.

See the Bamboo upgrade guide.

Bamboo 1.0

20 February 2007
Bamboo releases v6.0

The following pages can be found in the latest documentation for Bamboo:

- the Bamboo upgrade guide
- the Bamboo security advisories
- the End of support announcements for Bamboo
- the full release notes for every Bamboo release.

You can get automated notifications about major Bamboo releases by subscribing to the Atlassian blog.

The list below is a summary of the Bamboo releases. The changelogs included in the release notes (linked below) have details of the related bug-fix releases.

**Bamboo 6.7**

October 2018

- Parsing build warnings
- New VCS tasks
- Welcome IPv6
- Bamboo Docker images

- Deployment project configuration now in audit log

For more information, see Bamboo 6.7 Release Notes

**Bamboo 6.6**

June 2018

- Embedded Crowd

For more information, see Bamboo 6.6 Release Notes.

**Bamboo 6.5**

24 April 2018

- Bamboo Specs run on new repos
- Bamboo gets a new logo

For more information, see Bamboo 6.5 Release Notes.

**Bamboo 6.4**

21 February 2018

- Docker Runner
- Force-stop hanging builds

For more information, see Bamboo 6.4 Release Notes.

**Bamboo 6.3**

20 December 2017

- Bamboo YAML Specs
- New repository-stored Bamboo Specs protection
• Branching with multiple repositories
• Cleaning up permissions dependencies
• Nested variables

For more information, see Bamboo 6.3 Release Notes.

Bamboo 6.2
28 September 2017
• Changes to permissions
• Artifact handler
• Repository-stored Bamboo Specs
• Support for Bitbucket Server Smart Mirroring
• Bamboo YAML

For more information, see Bamboo 6.2 Release Notes.

Bamboo 6.1
20 July 2017
• Improvements to Bamboo Specs for plans
• Bamboo Specs for Deployments

For more information, see Bamboo 6.1 Release Notes.

Bamboo 6.0
26 April 2017
• Configuration as Code
• SQL Server JDBC driver update
• Pull request in the branch status page
• Fastlane and Xcode support

For more information, see Bamboo 6.0 Release Notes.

Bamboo 5.15
14 February 2017
• Git LFS support
• System-wide encryption
• Improvements to the Branch Status page
• Spring Scanner 2 support

For more information, see Bamboo 5.15 Release Notes.

Bamboo 5.14
27 October 2016
• Platform upgrades
• New Branch status page
• Build plans and deployment projects in YAML (beta)
• Override of repository settings for plan branches
• Enhancements for Subversion repository configuration
• New API for VCS repositories
• Bug fixes

For more information, see Bamboo 5.14 Release Notes.

Bamboo 5.13
24 August 2016
• Platform upgrades
• Deployment requirements
• SSH support for Bitbucket Cloud
• Improvements for the script task
• Absolute paths for artifacts
• Bug fixes
• API changes

For more information, see Bamboo 5.13 Release Notes.

Bamboo 5.12

24 May 2016

• Platform upgrades
• Quick Filters
• User deactivation directly from Bamboo
• Bug fixes

For more information, see Bamboo 5.12 Release Notes.

Bamboo 5.11

26 April 2016

• Platform upgrades
• Application Links upgrade to version 5.0.7
• Bamboo Instance Health check
• New Create repository permission
• REST API deployment triggers

For more information, see Bamboo 5.11 Release Notes.

Bamboo 5.10

19 January 2016

• Platform upgrades
• Bamboo build status for Bitbucket

For more information, see Bamboo 5.10 Release Notes.

Bamboo 5.9

11 June 2015

• Improved automatic branch management
• Improved Docker task customization
• AWS Code Deploy task for Bamboo
• Easier shared credentials management
• Future changes to on-disk directory layout: plan directory information REST API
• Bamboo Clover Plugin improvements

Read more in Bamboo 5.9 Release Notes.

For more information, see Bamboo upgrade guide.

Bamboo 5.8

17 March 2015

• Docker task for builds and deployments
• Improved integration with AWS
• Bamboo analytics added
• Support for Java 8
• Support for Java 7 is deprecated
• Support for Microsoft SQL Server 2005 and 2008 is deprecated
• Support for MySQL 5.1 is deprecated
• Support for PostgreSQL 8 is deprecated

Read more in the Bamboo 5.8 Release Notes.

See the Bamboo upgrade guide.
Bamboo 5.7

11 November 2014

- Control storage demands of deployment artifacts
- Take charge of build and release variables
- Manage remote Bamboo agents with Docker
- Use Bamboo with Node.js projects
- New Bamboo search tool for projects and plans
- Bamboo now supports Microsoft SQL Server 2012
- Support for Java 6 is deprecated
- Legacy Stash integration features removed

Read more in the Bamboo 5.7 Release Notes.

See the Bamboo upgrade guide.

Bamboo 5.6

29 July 2014

- Improved Stash integration:
  - Bamboo builds are triggered by Stash repo events
  - Bamboo plan branches update when branches are created or deleted in Stash
  - Bamboo build status is notified automatically to Stash
- Dedicated agents
- Clone deployment projects
- Deployments now appear in the activity streams for agents and builds
- Build queue improvements
- Project name is now editable
  - The legacy Stash notifications and web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7.

Read more in the Bamboo 5.6 Release Notes.

See the Bamboo upgrade guide.

Bamboo 5.5

28 April 2014

- Improved Stash integration
- Share repositories renamed to 'linked' repositories
- Stash legacy web repositories deprecated
- Bamboo menu layout change
- Subversion 1.8 is now supported
- Tomcat 5.5 and 6.0 are no longer supported.
- Internet Explorer 8 is no longer supported.

Read more in the Bamboo 5.5 release notes.

See the Bamboo upgrade guide.

Bamboo 5.4

11 February 2014

- Administration access navigation change
- Deployment workflow
- Deployment dashboard
- Reliability and stability
- Tomcat 5.5 and 6.0 deprecated.

Read more in the Bamboo 5.4 release notes.

See the Bamboo upgrade guide.

Bamboo 5.3

11 December 2013

- XSRF protection
- Deployment preview

Read more in the Bamboo 5.3 release notes.
See the Bamboo upgrade guide.

**Bamboo 5.2**
15 October 2013
- Branch deployments
- Advanced Gravatar support
- Branch checking interval editing

Read more in the [Bamboo 5.2 release notes](#).

See the [Bamboo upgrade guide](#).

**Bamboo 5.1**
13 September 2013
- Jira issue deployment reporting

Read more in the [Bamboo 5.1 release notes](#).

See the [Bamboo upgrade guide](#).

**Bamboo 5.0**
28 August 2013
- Deployment projects and environments
- Release versioning

Read more in the [Bamboo 5.0 release notes](#).

See the [Bamboo upgrade guide](#).

**Bamboo 4.4**
29 January 2013
- Jenkins importer
- Enhanced performance
- TestNG reports parser
- Selective task running
- Quick build number copying
- Server pausing

Read more in the [Bamboo 4.4 release notes](#).

See the [Bamboo upgrade guide](#).

**Bamboo 4.3**
30 October 2012
- Simple deployments to Tomcat
- Deploy to the Cloud with Heroku
- Upload files using SCP
- Build from any revision
- Runtime variables for Manual Stages
- Rebuild with one click
- Multiple build Triggers
- Build dependencies after all Stages
- Automatic dependencies for Maven 3
- Dashboard filtering
- Amazon Virtual Private Cloud for Elastic Bamboo
- Wallboard for Branches

Read more in the [Bamboo 4.3 release notes](#).

See the [Bamboo upgrade guide](#).
Bamboo 4.2
21 August 2012

- Notifications, build strategies and dependencies for plan branches
- Automatic linking of Jira issues to feature branches
- Bamboo build artifacts are linked from Jira issues
- Git support in the Bamboo Bitbucket connector
- Subversion 1.7 support
- UX improvements
- Mercurial commit isolation

Read more in the Bamboo 4.2 release notes.
See the Bamboo upgrade guide.

Bamboo 4.1
29 May 2012

- Get builds fixed faster with responsibilities
- Take action with Jira issue creation
- Get your team communicating with Hipchat notifications
- Welcome to the family, Stash!

Read more in the Bamboo 4.1 release notes.
See the Bamboo upgrade guide.

Bamboo 4.0
27 March 2012

- Automatically Build Branches
- Automatically Merge Branches using Gatekeeper and Branch Updater
- Manage Build Failures by Quarantining Intermittent Tests
- Fresh New User Experience

Read more in the Bamboo 4.0 release notes.
See the Bamboo upgrade guide.

Bamboo 3.4
14 December 2011

- Git Submodule Support
- Shared Repositories
- Agent Security Improvements
- New Email Templates
- Elastic Bamboo support for Microsoft Windows®

Read more in the Bamboo 3.4 release notes.
See the Bamboo upgrade guide.

Bamboo 3.3
11 October 2011

- Multiple Source Repositories
- Reload-able Plugins
- Source Repository User Aliases
- Automatic Agent Upgrades
- Fast, history-friendly tabbed navigation
- Commit Centric View

Read more in the Bamboo 3.3 release notes.
See the Bamboo upgrade guide.

Bamboo 3.2
26 July 2011

- Release Management
- Manual Stages
- Rerunning a Failed Stage
- Plan Filters on the Dashboard and Wallboard
- User Management via Jira
- Improved Application Linking

Read more in the Bamboo 3.2 release notes.

See the Bamboo upgrade guide.

Bamboo 3.1

10 May 2011

- Tasks
- Parameterized Builds
- .Net Support
- Bitbucket Support
- GitHub Support
- New Plugin Manager
- Support for Amazon EC2 Spot Instances
- Gravatar Support
- Improved Windows process handling

Read more in the Bamboo 3.1 release notes.

See the Bamboo upgrade guide.

Bamboo 3.0

16 February 2011

- Artifact Sharing
- Git Support
- User Interface Overhaul — Redesigned Plan Summary, Job Summary and Build Results. New look and feel.
- Scheduled Repository Polling
- Configuration Changes Captured in Audit Logs

Read more in the Bamboo 3.0 release notes.

See the Bamboo upgrade guide.

Bamboo 2.7

9 Nov 2010

- Build Stages — Map Your Build Process, Parallel Builds, Enhanced Plan Structure
- Simplified Plan Creation
- Concurrent Builds
- Mercurial Support
- Improved Wallboards
- New Plan and Job Configuration Summaries
- Recent History on Plan and Job Summaries
- Other User Interface Enhancements — New Breadcrumb Trail, Build Histories, Improved Build Result Summary Tabs

Read more in the Bamboo 2.7 release notes.

See the Bamboo upgrade guide.

Bamboo 2.6

1 June 2010

- Support for up to 100 Remote Agents
- Revamped Dashboard Pages and Other Usability Enhancements
- Performance and Security Improvements
- Automatically Managed Elastic Instances
- Grails Integration

Read more in the Bamboo 2.6 release notes.
See the Bamboo upgrade guide.

Bamboo 2.5

4 January 2010

- Maven Dependency Management
- Plan Import from a pom.xml
- Additional Bulk Actions
- Streamlined Plan Creation
- Express Setup Wizard

Read more in the Bamboo 2.5 release notes.

See the Bamboo upgrade guide.

Bamboo 2.4

6 October 2009

- Bamboo Gadgets in Jira
- Clover Enhancements
- REST Improvements
- Runtime Log4j Configuration

Read more in the Bamboo 2.4 release notes.

See the Bamboo upgrade guide.

Bamboo 2.3

6 August 2009

- Dependency Blocking Strategies
- New Build Notifications and Queue Reordering
- Bulk Actions
- Multiple Elastic Images
- Elastic Instance Scheduling
- PHPUnit Builder
- Bamboo REST APIs
- Plugins Changes

Read more in the Bamboo 2.3 release notes.

See the Bamboo upgrade guide.

Bamboo 2.2

9 March 2009

- Elastic Bamboo
- Customizable Email Templates
- Build Comment Notification Event
- Hanging Build Detection Event
- Faster Artifact Transfer
- Dependent Builds
- Agent Improvements

Read more in the Bamboo 2.2 release notes.

See the Bamboo upgrade guide.

Bamboo 2.1

5 August 2008

- Link Issues and Builds
- Specify the Issues that are Fixed by a Build
- Track the Builds for your Projects and Versions
- View Issues under Development
- Post Change Detection Plugin Point

Read more in the Bamboo 2.1 release notes.
See the Bamboo upgrade guide.

Bamboo 2.0

14 April 2008

- Distributed builds
- Capability matching
- Memory usage improvements
- Parallel VCS updates and checkouts
- Ability to force a 'clean build'
- Quiet Period functionality supported for Subversion & Perforce
- Bamboo Plugin for Confluence
- Support for Oracle and MS SQL Server databases
- Status Summary screens

Read more in the Bamboo 2.0 release notes.

See the Bamboo upgrade guide.

Bamboo 1.2

09 July 2007

- Permissions (global and plan-based)
- External database support
- Perforce triggering support
- Scheduled backups
- New Bundled NAnt plugin

Read more in the Bamboo 1.2 release notes.

See the Bamboo upgrade guide.

Bamboo 1.1

07 May 2007

- Advanced notifications - rules, triggers, preferences, dynamic recipients
- Build Metadata - pass them to your build, global variables, view them
- File Trigger Inclusions/Exclusions
- More pluggability
- Improved Maven 2 error log parsing
- LDAP and external user management support
- Dashboard loading has been improved

Read more in the Bamboo 1.1 release notes.

See the Bamboo upgrade guide.

Bamboo 1.0

20 February 2007

- All Plans tab

Read more in the Bamboo 1.0 release notes.

See the Bamboo upgrade guide.

Bamboo 6.2 Release Notes

September 2017

The Atlassian Bamboo team is proud to release Bamboo 6.2. If you're upgrading, read the Bamboo upgrade guide.
Changes to permissions

Bamboo 6.2 introduces multiple changes to permissions to make permissions management more transparent. Here's a summary of these changes:

Project admin

We've created a new permission called Project admin which allows Bamboo administrators to hand down some of their responsibilities for more effective management of the project. For instance, if Bamboo is used by 10 development teams, a global administrator can create 10 projects, one for each team, and delegate permissions management to team leaders by giving them the Project admin permissions. Users with the Project admin permissions can:

- manage permissions for the project
- manage permissions for all plans in a project
- change project settings

Create plan permission

The former Create plan global permission, now called Create, allows you to also create empty projects. Additionally, having the Create plan permission on a project-level already allows you to create new plans for that project even if you don't have the the global Create permission.

The already existing plan-level permissions (View, Edit, Build, Close, Admin) can now also be set on a project-level, which means that you will have them in all plans in your project. You can still set these permissions on the plan-level only just like before.

Permissions become additive

Once you're assigned permissions on any level, you'll automatically have permissions on lower levels. You can't override or remove permissions on lower levels. For example, if you have Create permission of a global level, you can create plans on all levels. Another example, if you have Build permission assigned to you on a project level and none assigned on the plan level explicitly, you will still have build permissions for that plan anyhow.

Projects menu

The new Projects menu lists all available projects together with their project codes, names and descriptions.

The project list, together with projects details, is available to everyone, who has access to this Bamboo instance including anonymous users when the anonymous access is enabled.

Artifact handler

With Bamboo 6.2 artifact handlers Bamboo administrators can control where artifacts produced by plans are stored. For instance, you can now tell Bamboo to store your artifacts in Amazon S3. Using artifact handlers can help you optimize the utilization of network bandwidth and filesystem space. You can activate each handler for shared and non-shared artifacts separately. The default artifact handler selection is configured by Bamboo administrator but can be overridden in a plan's configuration by users that have administration permission on the plan.
For more information on different types of artifact handlers in Bamboo, see Artifact handlers.

---

**Repository-stored Bamboo Specs**

6.2 release of Bamboo brings you possibility of storing your build plan configuration (Bamboo Specs) in your Bitbucket repository. Storing Bamboo Specs in a repository gives you access to history of plan specification, and makes it easy to revert to a particular moment in time. Additionally, by storing plans in repository users have not only information what changes were applied in the past, but also why they have been implemented this way giving them more context about the changes.

To allow Bamboo to scan a repository for Bamboo Specs, go to Administration > Linked repositories. In the Bamboo Specs tab, toggle Scan for Bamboo Specs.

**Linked repositories**

Repositories defined here are available to every plan. You can select these repositories in plans configuration. Changes to them will be applied to every plan that uses them.

![Linked repositories](image)

We’ve also added a new icon to the build history to help you identify the Bamboo Specs errors.

Read more about the repository-stored Specs here.

Although using Repository Stored Specs to manage deployment projects is possible with this release of Bamboo, the related error handling is going to be improved in the coming releases. This does not apply to IDE-driven Specs.

---

**Support for Bitbucket Server Smart Mirroring**

Bamboo introduces support for the Bitbucket Server Smart Mirroring capability. Smart Mirroring allows you to use mirror locations for storing your repository data instead of using remote location. This way you can clone and fetch repositories from the mirror and get identical content, only faster. If you want to give it a try, see Smart Mirroring.

Read more about all benefits of using Smart Mirroring in the Bitbucket Server documentation.

---

**Bamboo YAML**

This feature is released as a preview only and its scope might undergo changes in the future.

In version 6.2, Bamboo allows you to create simple plans using YAML as an alternative to using Bamboo Specs. If you have any suggestions or feedback related to Bamboo YAML, make sure to reach out to us. Read more about Bamboo YAML.
Proxy support for agent dependency caching

Startup time of agents can now be decreased by enabling content caching on your reverse proxy. Once you enable it on the proxy side, Bamboo will display the confirmation information in the agent log file.

Performance improvements

Plan deletion performance improvements

We've fixed the performance issue related to Bamboo plan deletion / expiry.

Bitbucket Server integration performance improvements

Significant performance improvements will be visible on instances with high total number of plan branches.

Bug fixes and improvement

You can view the detailed list of other fixed bugs at the bottom of this page.

The Atlassian Bamboo team is proud to release Bamboo 6.2. If you're upgrading, read the Bamboo upgrade guide.

Changes to permissions

Bamboo 6.2 introduces multiple changes to permissions to make permissions management more transparent. Here's a summary of these changes:

Project admin

We've created a new permission called **Project admin** which allows Bamboo administrators to hand down some of their responsibilities for more effective management of the project. For instance, if Bamboo is used by 10 development teams, a global administrator can create 10 projects, one for each team, and delegate permissions management to team leaders by giving them the **Project admin** permissions. Users with the **Project admin** permissions can:

- manage permissions for the project
- manage permissions for all plans in a project
- change project settings

Create plan permission

The former **Create plan** global permission, now called **Create**, allows you to also create empty projects. Additionally, having the **Create plan** permission on a project-level already allows you to create new plans for that project even if you don't have the the global **Create** permission.

The already existing plan-level permissions (**View**, **Edit**, **Build**, **Close**, **Admin**) can now also be set on a project-level, which means that you will have them in all plans in your project. You can still set these permissions on the plan-level only just like before.

Permissions become additive

Once you're assigned permissions on any level, you'll automatically have permissions on lower levels. You can't override or remove permissions on lower levels. For example, if you have **Create** permission of a global level, you can create plans on all levels. Another example, if you have **Build** permission assigned to you on a project level and none assigned on the plan level explicitly, you will still have build permissions for that plan anyhow.

Projects menu

The new **Projects** menu lists all available projects together with their project codes, names and descriptions.

The project list, together with projects details, is available to everyone, who has access to this Bamboo instance including anonymous users when the anonymous access is enabled.
Artifact handler

With Bamboo 6.2 artifact handlers Bamboo administrators can control where artifacts produced by plans are stored. For instance, you can now tell Bamboo to store your artifacts in Amazon S3. Using artifact handlers can help you optimize the utilization of network bandwidth and filesystem space. You can activate each handler for shared and non-shared artifacts separately. The default artifact handler selection is configured by Bamboo administrator but can be overridden in a plan’s configuration by users that have administration permission on the plan.

For more information on different types of artifact handlers in Bamboo, see Artifact handlers.

Repository-stored Bamboo Specs

6.2 release of Bamboo brings you possibility of storing your build plan configuration (Bamboo Specs) in your Bitbucket repository. Storing Bamboo Specs in a repository gives you access to history of plan specification, and makes it easy to revert to a particular moment in time. Additionally, by storing plans in repository users have not only information what changes were applied in the past, but also why they have been implemented this way giving them more context about the changes.

To allow Bamboo to scan a repository for Bamboo Specs, go to Administration > Linked repositories. In the Bamboo Specs tab, toggle Scan for Bamboo Specs.

Linked repositories

Repositories defined here are available to every plan. You can select these repositories in plans configuration. Changes to them will be applied to every plan that uses them.

We’ve also added a new icon to the build history to help you identify the Bamboo Specs errors.

Read more about the repository-stored Specs here.

Although using Repository Stored Specs to manage deployment projects is possible with this release of Bamboo, the related error handling is going to be improved in the coming releases. This does not apply to IDE-driven Specs.

Support for Bitbucket Server Smart Mirroring

Bamboo introduces support for the Bitbucket Server Smart Mirroring capability. Smart Mirroring allows you to use mirror locations for storing your repository data instead of using remote location. This way you can clone and fetch repositories from the mirror and get identical content, only faster. If you want to give it a try, see Smart Mirroring.

Read more about all benefits of using Smart Mirroring in the Bitbucket Server documentation.

Bamboo YAML
In version 6.2, Bamboo allows you to create simple plans using YAML as an alternative to using Bamboo Specs. If you have any suggestions or feedback related to Bamboo YAML, make sure to reach out to us. Read more about Bamboo YAML.

**Proxy support for agent dependency caching**

Startup time of agents can now be decreased by enabling content caching on your reverse proxy. Once you enable it on the proxy side, Bamboo will display the confirmation information in the agent log file.

**Performance improvements**

- **Plan deletion performance improvements**
  
  We’ve fixed the performance issue related to Bamboo plan deletion / expiry.

- **Bitbucket Server integration performance improvements**
  
  Significant performance improvements will be visible on instances with high total number of plan branches.

**Bug fixes and improvement**

You can view the detailed list of other fixed bugs at the bottom of this page.

### Bamboo 6.2 Release Notes v6.3

**September 2017**

The Atlassian Bamboo team is proud to release Bamboo 6.2. If you’re upgrading, read the Bamboo upgrade guide.

---

## Changes to permissions

Bamboo 6.2 introduces multiple changes to permissions to make permissions management more transparent. Here’s a summary of these changes:

### Project admin

We’ve created a new permission called **Project admin** which allows Bamboo administrators to hand down some of their responsibilities for more effective management of the project. For instance, if Bamboo is used by 10 development teams, a global administrator can create 10 projects, one for each team, and delegate permissions management to team leaders by giving them the **Project admin** permissions. Users with the **Project admin** permissions can:

- manage permissions for the project
- manage permissions for all plans in a project
- change project settings

### Create plan permission

The former **Create plan** global permission, now called **Create**, allows you to also create empty projects. Additionally, having the **Create plan** permission on a project-level already allows you to create new plans for that project even if you don’t have the the global **Create** permission.

The already existing plan-level permissions (**View**, **Edit**, **Build**, **Close**, **Admin**) can now also be set on a project-level, which means that you will have them in all plans in your project. You can still set these permissions on the plan-level only just like before.

### Permissions become additive

Once you’re assigned permissions on any level, you’ll automatically have permissions on lower levels. You can’t override or remove permissions on lower levels. For example, if you have **Create** permission of a global level, you can create plans on all levels. Another example, if you have **Build** permission assigned to you on a project level and none assigned on the plan level explicitly, you will still have build permissions for that plan anyhow.

### Projects menu

The new **Projects** menu lists all available projects together with their project codes, names and descriptions.

The project list, together with projects details, is available to everyone, who has access to this Bamboo instance including anonymous users when the anonymous access is enabled.

BAM-18630  XSS in release name
BAM-19662  XSS in the viewDeploymentVersionJiraissuesDialog resource through the name of a release - CVE-2017-18041
BAM-19661  XSS in the viewDeploymentVersionCommits resource through the name of a release - CVE-2017-18040
BAM-16989  Docker Task configuration doesn't expand environment variables
BAM-15484  If artifact downloader task is misconfigured, deployment is stuck in queued state

Showing 10 out of 59 issues
Artifact handler

With Bamboo 6.2 artifact handlers Bamboo administrators can control where artifacts produced by plans are stored. For instance, you can now tell Bamboo to store your artifacts in Amazon S3. Using artifact handlers can help you optimize the utilization of network bandwidth and filesystem space. You can activate each handler for shared and non-shared artifacts separately. The default artifact handler selection is configured by Bamboo administrator but can be overridden in a plan’s configuration by users that have administration permission on the plan.

For more information on different types of artifact handlers in Bamboo, see Artifact handlers.

Repository-stored Bamboo Specs

6.2 release of Bamboo brings you possibility of storing your build plan configuration (Bamboo Specs) in your Bitbucket repository. Storing Bamboo Specs in a repository gives you access to history of plan specification, and makes it easy to revert to a particular moment in time. Additionally, by storing plans in repository users have not only information what changes were applied in the past, but also why they have been implemented this way giving them more context about the changes.

To allow Bamboo to scan a repository for Bamboo Specs, go to Administration > Linked repositories. In the Bamboo Specs tab, toggle Scan for Bamboo Specs.

We’ve also added a new icon to the build history to help you identify the Bamboo Specs errors.

Read more about the repository-stored Specs here.

Although using Repository Stored Specs to manage deployment projects is possible with this release of Bamboo, the related error handling is going to be improved in the coming releases. This does not apply to IDE-driven Specs.
Support for Bitbucket Server Smart Mirroring

Bamboo introduces support for the Bitbucket Server Smart Mirroring capability. Smart Mirroring allows you to use mirror locations for storing your repository data instead of using remote location. This way you can clone and fetch repositories from the mirror and get identical content, only faster. If you want to give it a try, see Smart Mirroring.

Read more about all benefits of using Smart Mirroring in the Bitbucket Server documentation.

Bamboo YAML

This feature is released as a preview only and its scope might undergo changes in the future.

In version 6.2, Bamboo allows you to create simple plans using YAML as an alternative to using Bamboo Specs. If you have any suggestions or feedback related to Bamboo YAML, make sure to reach out to us. Read more about Bamboo YAML.

Proxy support for agent dependency caching

Startup time of agents can now be decreased by enabling content caching on your reverse proxy. Once you enable it on the proxy side, Bamboo will display the confirmation information in the agent log file.

Performance improvements

Plan deletion performance improvements

We’ve fixed the performance issue related to Bamboo plan deletion / expiry.

Bitbucket Server integration performance improvements

Significant performance improvements will be visible on instances with high total number of plan branches.

Bug fixes and improvement

You can view the detailed list of other fixed bugs at the bottom of this page.

Bamboo 6.2 Release Notes v6.5

September 2017

The Atlassian Bamboo team is proud to release Bamboo 6.2. If you're upgrading, read the Bamboo upgrade guide.

Changes to permissions

Bamboo 6.2 introduces multiple changes to permissions to make permissions management more transparent. Here's a summary of these changes:

Project admin

We’ve created a new permission called Project admin which allows Bamboo administrators to hand down some of their responsibilities for more effective management of the project. For instance, if Bamboo is used by 10 development teams, a global administrator can create 10 projects, one for each team, and delegate permissions management to team leaders by giving them the Project admin permissions. Users with the Project admin permissions can:

• manage permissions for the project
• manage permissions for all plans in a project
• change project settings

Create plan permission

The former Create plan global permission, now called Create, allows you to also create empty projects. Additionally, having the Create plan permission on a project-level already allows you to create new plans for that project even if you don’t have the the global Create permission.

The already existing plan-level permissions (View, Edit, Build, Close, Admin) can now also be set on a project-level, which means that you will have them in all plans in your project. You can still set these permissions on the plan-level only just like before.

Permissions become additive

Once you’re assigned permissions on any level, you'll automatically have permissions on lower levels. You can’t override or remove permissions on lower levels. For example, if you have Create permission of a global level, you can create plans on all levels. Another example, if you have Build permission assigned to you on a project level and none assigned on the plan level explicitly, you will still have build permissions for that plan anyhow.

Projects menu

The new Projects menu lists all available projects together with their project codes, names and descriptions.

The project list, together with projects details, is available to everyone, who has access to this Bamboo instance including anonymous users when the anonymous access is enabled.
Artifact handler

With Bamboo 6.2 artifact handlers Bamboo administrators can control where artifacts produced by plans are stored. For instance, you can now tell Bamboo to store your artifacts in Amazon S3. Using artifact handlers can help you optimize the utilization of network bandwidth and filesystem space. You can activate each handler for shared and non-shared artifacts separately. The default artifact handler selection is configured by Bamboo administrator but can be overridden in a plan's configuration by users that have administration permission on the plan.

For more information on different types of artifact handlers in Bamboo, see Artifact handlers.

Repository-stored Bamboo Specs

6.2 release of Bamboo brings you possibility of storing your build plan configuration (Bamboo Specs) in your Bitbucket repository. Storing Bamboo Specs in a repository gives you access to history of plan specification, and makes it easy to revert to a particular moment in time. Additionally, by storing plans in repository users have not only information what changes were applied in the past, but also why they have been implemented this way giving them more context about the changes.

To allow Bamboo to scan a repository for Bamboo Specs, go to Administration > Linked repositories. In the Bamboo Specs tab, toggle Scan for Bamboo Specs.

We've also added a new icon to the build history to help you identify the Bamboo Specs errors.

Read more about the repository-stored Specs [here](#).
Support for Bitbucket Server Smart Mirroring

Bamboo introduces support for the Bitbucket Server Smart Mirroring capability. Smart Mirroring allows you to use mirror locations for storing your repository data instead of using remote location. This way you can clone and fetch repositories from the mirror and get identical content, only faster. If you want to give it a try, see Smart Mirroring.

Read more about all benefits of using Smart Mirroring in the Bitbucket Server documentation.

Bamboo YAML

This feature is released as a preview only and its scope might undergo changes in the future.

In version 6.2, Bamboo allows you to create simple plans using YAML as an alternative to using Bamboo Specs. If you have any suggestions or feedback related to Bamboo YAML, make sure to reach out to us. Read more about Bamboo YAML.

Proxy support for agent dependency caching

Startup time of agents can now be decreased by enabling content caching on your reverse proxy. Once you enable it on the proxy side, Bamboo will display the confirmation information in the agent log file.

Performance improvements

Plan deletion performance improvements

We've fixed the performance issue related to Bamboo plan deletion / expiry.

Bitbucket Server integration performance improvements

Significant performance improvements will be visible on instances with high total number of plan branches.

Bug fixes and improvement

You can view the detailed list of other fixed bugs at the bottom of this page.

Bamboo 5.15 Release Notes

February 2017

The Atlassian Bamboo team are excited to release Bamboo 5.15. If you're upgrading, read the Bamboo upgrade guide.

Git LFS support

For Git, Bitbucket Cloud Git, and Bitbucket Server repositories, Bamboo 5.15 is introducing Git LFS support.

Git LFS allows you to save time and space by replacing large files such with pointers inside Git, while storing the actual content of your files on a remote server.

Just select the Enable Git LFS support checkbox in the advanced options of your repository to enable this feature. When this option is selected, Bamboo will fetch Git LFS content as part of the checkout task and Git repository cache preparation.

System-wide encryption

Now, more than ever, you can be sure that sensitive data that you store in Bamboo is well protected with the central encryption service.

For details on how Bamboo protects your data, see System-wide encryption.

Improvements to the Branch Status page
In Bamboo 5.15, we have fixed a number of small issues in the Branch Status page to make your user experience even better.

- Introducing plan sorting by plan name, build status (default), and completion date. Your choice is saved and kept for all repositories and branches even after refreshing the page or logging out.

- The new favicon with the status of a branch which allows you to monitor the condition of your branch at a quick glance.

- When opening a dropdown to select a repository or branch, the most recently visited items are now displayed first.
- New animations were added to help you distinguish better newly added or deleted plans.
- In the Add plans picker, projects names are now displayed next to plan names to help you differentiate between plans quickly.

Spring Scanner 2 support

Bamboo 5.15 provides support for Spring Scanner 2 library set. Read more about Spring Scanner.

Bug fixes and improvements

You can view the detailed list of fixed bugs at the bottom of this page.

**Git LFS support**

For Git, Bitbucket Cloud Git, and Bitbucket Server repositories, Bamboo 5.15 is introducing Git LFS support.

Git LFS allows you to save time and space by replacing large files such with pointers inside Git, while storing the actual content of your files on a remote server.

Just select the Enable Git LFS support checkbox in the advanced options of your repository to enable this feature. When this option is selected, Bamboo will fetch Git LFS content as part of the checkout task and Git repository cache preparation.

**System-wide encryption**

Now, more than ever, you can be sure that sensitive data that you store in Bamboo is well protected with the central encryption service. For details on how Bamboo protects your data, see System-wide encryption.

**Improvements to the Branch Status page**

In Bamboo 5.15, we have fixed a number of small issues in the Branch Status page to make your user experience even better.

- Introducing plan sorting by plan name, build status (default), and completion date. Your choice is saved and kept for all repositories and branches even after refreshing the page or logging out.

- The new favicon with the status of a branch which allows you to monitor the condition of your branch at a quick glance.

- When opening a dropdown to select a repository or branch, the most recently visited items are now displayed first.
- New animations were added to help you distinguish better newly added or deleted plans.
- In the Add plans picker, projects names are now displayed next to plan names to help you differentiate between plans quickly.

.Bamboo releases v5.14

The following pages can be found in the latest documentation for Bamboo:

- the Bamboo upgrade guide
- the Bamboo security advisories
- the End of support announcements for Bamboo
- the full release notes for every Bamboo release.

You can get automated notifications about major Bamboo releases by subscribing to the Atlassian blog.

The list below is a summary of the Bamboo releases. The changelogs included in the release notes (linked below) have details of the related bug-fix releases.

**Bamboo 6.7**

October 2018

- Parsing build warnings
- New VCS tasks
- Welcome IPv6
- Bamboo Docker images

- Deployment project configuration now in audit log

For more information, see Bamboo 6.7 Release Notes

**Bamboo 6.6**

June 2018

- Embedded Crowd

For more information, see Bamboo 6.6 Release Notes.

**Bamboo 6.5**

24 April 2018

- Bamboo Specs run on new repos
- Bamboo gets a new logo
For more information, see Bamboo 6.5 Release Notes.

**Bamboo 6.4**

21 February 2018

- Docker Runner
- Force-stop hanging builds

For more information, see Bamboo 6.4 Release Notes.

**Bamboo 6.3**

20 December 2017

- Bamboo YAML Specs
- New repository-stored Bamboo Specs protection
- Branching with multiple repositories
- Cleaning up permissions dependencies
- Nested variables

For more information, see Bamboo 6.3 Release Notes.

**Bamboo 6.2**

28 September 2017

- Changes to permissions
- Artifact handler
- Repository-stored Bamboo Specs
- Support for Bitbucket Server Smart Mirroring
- Bamboo YAML

For more information, see Bamboo 6.2 Release Notes.

**Bamboo 6.1**

20 July 2017

- Improvements to Bamboo Specs for plans
- Bamboo Specs for Deployments

For more information, see Bamboo 6.1 Release Notes.

**Bamboo 6.0**

26 April 2017

- Configuration as Code
- SQL Server JDBC driver update
- Pull request in the branch status page
- Fastlane and Xcode support

For more information, see Bamboo 6.0 Release Notes.

**Bamboo 5.15**

14 February 2017

- Git LFS support
- System-wide encryption
- Improvements to the Branch Status page
- Spring Scanner 2 support

For more information, see Bamboo 5.15 Release Notes.
Bamboo 5.14

27 October 2016

- Platform upgrades
- New Branch status page
- Build plans and deployment projects in YAML (beta)
- Override of repository settings for plan branches
- Enhancements for Subversion repository configuration
- New API for VCS repositories
- Bug fixes

For more information, see Bamboo 5.14 Release Notes.

Bamboo 5.13

24 August 2016

- Platform upgrades
- Deployment requirements
- SSH support for Bitbucket Cloud
- Improvements for the script task
- Absolute paths for artifacts
- Bug fixes
- API changes

For more information, see Bamboo 5.13 Release Notes.

Bamboo 5.12

24 May 2016

- Platform upgrades
- Quick Filters
- User deactivation directly from Bamboo
- Bug fixes

For more information, see Bamboo 5.12 Release Notes.

Bamboo 5.11

26 April 2016

- Platform upgrades
- Application Links upgrade to version 5.0.7
- Bamboo Instance Health check
- New Create repository permission
- REST API deployment triggers

For more information, see Bamboo 5.11 Release Notes.

Bamboo 5.10

19 January 2016

- Platform upgrades
- Bamboo build status for Bitbucket

For more information, see Bamboo 5.10 Release Notes.

Bamboo 5.9

11 June 2015

- Improved automatic branch management
- Improved Docker task customization
- AWS Code Deploy task for Bamboo
- Easier shared credentials management
- Future changes to on-disk directory layout: plan directory information REST API
- Bamboo Clover Plugin improvements

For more information, see Bamboo 5.9 Release Notes.
Read more in Bamboo 5.9 Release Notes.
For more information, see Bamboo upgrade guide.

Bamboo 5.8

17 March 2015

- Docker task for builds and deployments
- Improved integration with AWS
- Bamboo analytics added
- Support for Java 8
- Support for Java 7 is deprecated
- Support for Microsoft SQL Server 2005 and 2008 is deprecated
- Support for MySQL 5.1 is deprecated
- Support for PostgreSQL 8 is deprecated

Read more in the Bamboo 5.8 Release Notes.
See the Bamboo upgrade guide.

Bamboo 5.7

11 November 2014

- Control storage demands of deployment artifacts
- Take charge of build and release variables
- Manage remote Bamboo agents with Docker
- Use Bamboo with Node.js projects
- New Bamboo search tool for projects and plans
- Bamboo now supports Microsoft SQL Server 2012
- Support for Java 6 is deprecated
- Legacy Stash integration features removed

Read more in the Bamboo 5.7 Release Notes.
See the Bamboo upgrade guide.

Bamboo 5.6

29 July 2014

- Improved Stash integration:
  - Bamboo builds are triggered by Stash repo events
  - Bamboo plan branches update when branches are created or deleted in Stash
  - Bamboo build status is notified automatically to Stash
- Dedicated agents
- Clone deployment projects
- Deployments now appear in the activity streams for agents and builds
- Build queue improvements
- Project name is now editable
- The legacy Stash notifications and web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7.

Read more in the Bamboo 5.6 Release Notes.
See the Bamboo upgrade guide.

Bamboo 5.5

28 April 2014

- Improved Stash integration
- Share repositories renamed to 'linked' repositories
- Stash legacy web repositories deprecated
- Bamboo menu layout change
- Subversion 1.8 is now supported
- Tomcat 5.5 and 6.0 are no longer supported.
- Internet Explorer 8 is no longer supported.

Read more in the Bamboo 5.5 release notes.
See the Bamboo upgrade guide.
Bamboo 5.4
11 February 2014
- Administration access navigation change
- Deployment workflow
- Deployment dashboard
- Reliability and stability
- Tomcat 5.5 and 6.0 deprecated.

Read more in the Bamboo 5.4 release notes.
See the Bamboo upgrade guide.

Bamboo 5.3
11 December 2013
- XSRF protection
- Deployment preview

Read more in the Bamboo 5.3 release notes.
See the Bamboo upgrade guide.

Bamboo 5.2
15 October 2013
- Branch deployments
- Advanced Gravatar support
- Branch checking interval editing

Read more in the Bamboo 5.2 release notes.
See the Bamboo upgrade guide.

Bamboo 5.1
13 September 2013
- Jira issue deployment reporting

Read more in the Bamboo 5.1 release notes.
See the Bamboo upgrade guide.

Bamboo 5.0
28 August 2013
- Deployment projects and environments
- Release versioning

Read more in the Bamboo 5.0 release notes.
See the Bamboo upgrade guide.

Bamboo 4.4
29 January 2013
- Jenkins importer
- Enhanced performance
- TestNG reports parser
- Selective task running
- Quick build number copying
- Server pausing

Read more in the Bamboo 4.4 release notes.
See the Bamboo upgrade guide.
Bamboo 4.3
30 October 2012

- Simple deployments to Tomcat
- Deploy to the Cloud with Heroku
- Upload files using SCP
- Build from any revision
- Runtime variables for Manual Stages
- Rebuild with one click
- Multiple build Triggers
- Build dependencies after all Stages
- Automatic dependencies for Maven 3
- Dashboard filtering
- Amazon Virtual Private Cloud for Elastic Bamboo
- Wallboard for Branches

Read more in the Bamboo 4.3 release notes.
See the Bamboo upgrade guide.

Bamboo 4.2
21 August 2012

- Notifications, build strategies and dependencies for plan branches
- Automatic linking of Jira issues to feature branches
- Bamboo build artifacts are linked from Jira issues
- Git support in the Bamboo Bitbucket connector
- Subversion 1.7 support
- UX improvements
- Mercurial commit isolation

Read more in the Bamboo 4.2 release notes.
See the Bamboo upgrade guide.

Bamboo 4.1
29 May 2012

- Get builds fixed faster with responsibilities
- Take action with Jira issue creation
- Get your team communicating with Hipchat notifications
- Welcome to the family, Stash!

Read more in the Bamboo 4.1 release notes.
See the Bamboo upgrade guide.

Bamboo 4.0
27 March 2012

- Automatically Build Branches
- Automatically Merge Branches using Gatekeeper and Branch Updater
- Manage Build Failures by Quarantining Intermittent Tests
- Fresh New User Experience

Read more in the Bamboo 4.0 release notes.
See the Bamboo upgrade guide.

Bamboo 3.4
14 December 2011

- Git Submodule Support
- Shared Repositories
- Agent Security Improvements
- New Email Templates
- Elastic Bamboo support for Microsoft Windows®
Read more in the Bamboo 3.4 release notes.
See the Bamboo upgrade guide.

Bamboo 3.3
11 October 2011

- Multiple Source Repositories
- Reload-able Plugins
- Source Repository User Aliases
- Automatic Agent Upgrades
- Fast, history-friendly tabbed navigation
- Commit Centric View

Read more in the Bamboo 3.3 release notes.
See the Bamboo upgrade guide.

Bamboo 3.2
26 July 2011

- Release Management
- Manual Stages
- Rerunning a Failed Stage
- Plan Filters on the Dashboard and Wallboard
- User Management via Jira
- Improved Application Linking

Read more in the Bamboo 3.2 release notes.
See the Bamboo upgrade guide.

Bamboo 3.1
10 May 2011

- Tasks
- Parameterized Builds
- .Net Support
- Bitbucket Support
- GitHub Support
- New Plugin Manager
- Support for Amazon EC2 Spot Instances
- Gravatar Support
- Improved Windows process handling

Read more in the Bamboo 3.1 release notes.
See the Bamboo upgrade guide.

Bamboo 3.0
16 February 2011

- Artifact Sharing
- Git Support
- User Interface Overhaul — Redesigned Plan Summary, Job Summary and Build Results. New look and feel.
- Scheduled Repository Polling
- Configuration Changes Captured in Audit Logs

Read more in the Bamboo 3.0 release notes.
See the Bamboo upgrade guide.

Bamboo 2.7
9 Nov 2010

- Build Stages — Map Your Build Process, Parallel Builds, Enhanced Plan Structure
- Simplified Plan Creation
- Concurrent Builds
• Mercurial Support
• Improved Wallboards
• New Plan and Job Configuration Summaries
• Recent History on Plan and Job Summaries
• Other User Interface Enhancements — New Breadcrumb Trail, Build Histories, Improved Build Result Summary Tabs

Read more in the Bamboo 2.7 release notes.

See the Bamboo upgrade guide.

Bamboo 2.6
1 June 2010
• Support for up to 100 Remote Agents
• Revamped Dashboard Pages and Other Usability Enhancements
• Performance and Security Improvements
• Automatically Managed Elastic Instances
• Grails Integration

Read more in the Bamboo 2.6 release notes.

See the Bamboo upgrade guide.

Bamboo 2.5
4 January 2010
• Maven Dependency Management
• Plan Import from a pom.xml
• Additional Bulk Actions
• Streamlined Plan Creation
• Express Setup Wizard

Read more in the Bamboo 2.5 release notes.

See the Bamboo upgrade guide.

Bamboo 2.4
6 October 2009
• Bamboo Gadgets in Jira
• Clover Enhancements
• REST Improvements
• Runtime Log4j Configuration

Read more in the Bamboo 2.4 release notes.

See the Bamboo upgrade guide.

Bamboo 2.3
6 August 2009
• Dependency Blocking Strategies
• New Build Notifications and Queue Reordering
• Bulk Actions
• Multiple Elastic Images
• Elastic Instance Scheduling
• PHPUnit Builder
• Bamboo REST APIs
• Plugins Changes

Read more in the Bamboo 2.3 release notes.

See the Bamboo upgrade guide.

Bamboo 2.2
9 March 2009
• Elastic Bamboo
• Customizable Email Templates
• Build Comment Notification Event
• Hanging Build Detection Event
• Faster Artifact Transfer
• Dependent Builds
• Agent Improvements

Read more in the Bamboo 2.2 release notes.
See the Bamboo upgrade guide.

Bamboo 2.1
5 August 2008
• Link Issues and Builds
• Specify the Issues that are Fixed by a Build
• Track the Builds for your Projects and Versions
• View Issues under Development
• Post Change Detection Plugin Point

Read more in the Bamboo 2.1 release notes.
See the Bamboo upgrade guide.

Bamboo 2.0
14 April 2008
• Distributed builds
• Capability matching
• Memory usage improvements
• Parallel VCS updates and checkouts
• Ability to force a 'clean build'
• Quiet Period functionality supported for Subversion & Perforce
• Bamboo Plugin for Confluence
• Support for Oracle and MS SQL Server databases
• Status Summary screens

Read more in the Bamboo 2.0 release notes.
See the Bamboo upgrade guide.

Bamboo 1.2
09 July 2007
• Permissions (global and plan-based)
• External database support
• Perforce triggering support
• Scheduled backups
• New Bundled NAnt plugin

Read more in the Bamboo 1.2 release notes.
See the Bamboo upgrade guide.

Bamboo 1.1
07 May 2007
• Advanced notifications - rules, triggers, preferences, dynamic recipients
• Build Metadata - pass them to your build, global variables, view them
• File Trigger Inclusions/Exclusions
• More pluggability
• Improved Maven 2 error log parsing
• LDAP and external user management support
• Dashboard loading has been improved

Read more in the Bamboo 1.1 release notes.
See the Bamboo upgrade guide.
Bamboo 6.0 Release Notes

April 2017

The Atlassian Bamboo team are excited to release Bamboo 6.0. If you're upgrading, read the Bamboo upgrade guide.

Configuration as code

Configuration as code is now available in Bamboo! You can start storing your build plan configuration as code for easier automation, change tracking, validation, and much more. Read all about other benefits of using configuration as code in Bamboo Specs. We've also prepared a tutorial that will help you create a simple plan in no time. For behind-the-scenes information about the Bamboo Specs library, see our detailed reference documentation.

Support for pull requests

Starting from version 6.0, Bamboo can create plan branches whenever a pull request is created. Create plan branch when ready to share your work with teammates and the CI system. Bamboo will detect new pull requests and create a plan branch.

Pull requests join the branch status page

In Bamboo 6.0, the branch status page gives you even more insight into your environment with a new section showing pull requests for the selected VCS branch. To learn more, see Using the branch status page.
Fastlane and Xcode support

Bamboo 6.0 introduces support for Fastlane allowing you to run Fastlane processes and discover Fastlane capabilities in Bamboo agents. Additionally, the XCode plugin is officially supported by Atlassian and from now on is going to be bundled with Bamboo.

SQL Server JDBC driver update

As of version 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver. To learn more about this change, see here. Also check our upgrade guide to make sure that your upgrade goes smoothly after this change.

Bug fixes and improvements

- A long standing bug where remote events/triggers from Bitbucket Server to Bamboo stop working after restart was identified and has been fixed in Bitbucket Server. The fix requires you to upgrade to Bitbucket Server 4.14.3+ or apply the workaround in the bug report.
  - BSERV-9710 - Remote events between Bitbucket Server and Bamboo/JIRA/FishEye don't work immediately after restart [CLOSED]

- Bamboo 6.0 provides you with security bug fix for
  - BAM-18242 - Apache Struts 2 Remote Code Execution (CVE-2017-5638) [RESOLVED]

You can view the detailed list of other fixed bugs at the bottom of this page.

Changelog

10 October 2017 - Bamboo 6.0.5

This is a security fix release. We've fixed the following issues:

.Bamboo 6.0 Release Notes v6.3

April 2017

The Atlassian Bamboo team are excited to release Bamboo 6.0. If you’re upgrading, read the Bamboo upgrade guide.

Configuration as code

Configuration as code is now available in Bamboo! You can start storing your build plan configuration as code for easier automation, change tracking, validation, and much more. Read all about other benefits of using configuration as code in Bamboo Specs. We've also prepared a tutorial that will help you create a simple plan in no time. For behind-the-scenes information about the Bamboo Specs library, see our detailed reference documentation.

Support for pull requests

Starting from version 6.0, Bamboo can create plan branches whenever a pull request is created. Create plan branch when ready to share your work with teammates and the CI system. Bamboo will detect new pull requests and create a plan branch.
Pull requests join the branch status page

In Bamboo 6.0, the branch status page gives you even more insight into your environment with a new section showing pull requests for the selected VCS branch. To learn more, see Using the branch status page.

Fastlane and Xcode support

Bamboo 6.0 introduces support for Fastlane allowing you to run Fastlane processes and discover Fastlane capabilities in Bamboo agents. Additionally, the XCode plugin is officially supported by Atlassian and from now on is going to be bundled with Bamboo.

SQL Server JDBC driver update

As of version 6.0, SQL Server jTDS driver is replaced with the official Microsoft JDBC driver. To learn more about this change, see here. Also check our upgrade guide to make sure that your upgrade goes smoothly after this change.

Bug fixes and improvements

- A long standing bug where remote events/triggers from Bitbucket Server to Bamboo stop working after restart was identified and has been fixed in Bitbucket Server. The fix requires you to upgrade to Bitbucket Server 4.14.3+ or apply the workaround in the...
bug report.

- **BSERV-9710** - Remote events between Bitbucket Server and Bamboo/JIRA/FishEye don't work immediately after restart [CLOSED]
- Bamboo 6.0 provides you with security bug fix for

  - **BAM-18242** - Apache Struts 2 Remote Code Execution (CVE-2017-5638) [RESOLVED]

You can view the detailed list of other fixed bugs at the bottom of this page.

Bamboo 6.1 Release Notes

July 2017

The Atlassian Bamboo team is excited to release Bamboo 6.1. If you're upgrading, read the Bamboo upgrade guide.
Improvements to Bamboo Specs for plans

We bring you a number of improvements to Bamboo Specs to make configuration as code even easier. With Bamboo Specs, in version 6.1 you can:

- Manage plan permissions to control which users have access to various functions of the build plan.
- Set up notifications about build results so that you can find out immediately about the success or failure of your builds.
- Configure Miscellaneous plugins used for various additional functionalities for plans and jobs like Build expiry.
- Define dependencies between various plans.

Make sure to check out our Bamboo Specs reference documentation for detailed description of these improvements along with code samples and upgrade today for more complete experience of using Bamboo Specs.

Bamboo Specs for Deployments

A deployment project in Bamboo is a container for holding the software project you are deploying: releases that have been built and tested, and the environments to which releases are deployed. Starting with Bamboo 6.1, you can configure deployment projects and their automatic triggering using Bamboo Specs.

Visit our Bamboo Specs reference documentation, to learn how to do it.

Bug fixes and improvements

- **BAM-14355** - Change default (from bamboo deployments) of "Releases from branches will default to using the branch name suffixed with the build number of the build result"  [RESOLVED]
- **BAM-14422** - How to change default (from bamboo deployments) of "Releases from branches will default to using the branch name suffixed with the build number of the build result"  [RESOLVED]
- **BAM-17197** - Extend the Web Repository Viewer Module so it can also render GitHub commits  [RESOLVED]
- **BAM-18083** - Cannot select a variable for version auto-increment without admin access in Bamboo  [RESOLVED]
- **BAM-18427** - Allow deployment using CodeDeploy tasks to China (Beijing) region  [RESOLVED]

You can view the detailed list of other fixed bugs at the bottom of this page.

Changelog

10 October 2017 - Bamboo 6.1.4

This is a security fix release. We've fixed the following issues in it:

.Bamboo releases v6.1

The following pages can be found in the latest documentation for Bamboo:

- the Bamboo upgrade guide
- the Bamboo security advisories
- the End of support announcements for Bamboo
- the full release notes for every Bamboo release.

You can get automated notifications about major Bamboo releases by subscribing to the Atlassian blog.

The list below is a summary of the Bamboo releases. The changelogs included in the release notes (linked below) have details of the related bug-fix releases.

Bamboo 6.7

October 2018

- Parsing build warnings
- New VCS tasks
- Welcome IPv6
- Bamboo Docker images

- Deployment project configuration now in audit log
Bamboo 6.7

For more information, see Bamboo 6.7 Release Notes

Bamboo 6.6

June 2018

- Embedded Crowd

For more information, see Bamboo 6.6 Release Notes.

Bamboo 6.5

24 April 2018

- Bamboo Specs run on new repos
- Bamboo gets a new logo

For more information, see Bamboo 6.5 Release Notes.

Bamboo 6.4

21 February 2018

- Docker Runner
- Force-stop hanging builds

For more information, see Bamboo 6.4 Release Notes.

Bamboo 6.3

20 December 2017

- Bamboo YAML Specs
- New repository-stored Bamboo Specs protection
- Branching with multiple repositories
- Cleaning up permissions dependencies
- Nested variables

For more information, see Bamboo 6.3 Release Notes.

Bamboo 6.2

28 September 2017

- Changes to permissions
- Artifact handler
- Repository-stored Bamboo Specs
- Support for Bitbucket Server Smart Mirroring
- Bamboo YAML

For more information, see Bamboo 6.2 Release Notes.

Bamboo 6.1

20 July 2017

- Improvements to Bamboo Specs for plans
- Bamboo Specs for Deployments

For more information, see Bamboo 6.1 Release Notes.

Bamboo 6.0

26 April 2017
• Configuration as Code
• SQL Server JDBC driver update
• Pull request in the branch status page
• Fastlane and Xcode support

For more information, see Bamboo 6.0 Release Notes.

Bamboo 5.15
14 February 2017
• Git LFS support
• System-wide encryption
• Improvements to the Branch Status page
• Spring Scanner 2 support

For more information, see Bamboo 5.15 Release Notes.

Bamboo 5.14
27 October 2016
• Platform upgrades
• New Branch status page
• Build plans and deployment projects in YAML (beta)
• Override of repository settings for plan branches
• Enhancements for Subversion repository configuration
• New API for VCS repositories
• Bug fixes

For more information, see Bamboo 5.14 Release Notes.

Bamboo 5.13
24 August 2016
• Platform upgrades
• Deployment requirements
• SSH support for Bitbucket Cloud
• Improvements for the script task
• Absolute paths for artifacts
• Bug fixes
• API changes

For more information, see Bamboo 5.13 Release Notes.

Bamboo 5.12
24 May 2016
• Platform upgrades
• Quick Filters
• User deactivation directly from Bamboo
• Bug fixes

For more information, see Bamboo 5.12 Release Notes.

Bamboo 5.11
26 April 2016
• Platform upgrades
• Application Links upgrade to version 5.0.7
• Bamboo Instance Health check
• New Create repository permission
• REST API deployment triggers

For more information, see Bamboo 5.11 Release Notes.
Bamboo 5.10
19 January 2016
• Platform upgrades
• Bamboo build status for Bitbucket

For more information, see Bamboo 5.10 Release Notes.

Bamboo 5.9
11 June 2015
• Improved automatic branch management
• Improved Docker task customization
• AWS Code Deploy task for Bamboo
• Easier shared credentials management
• Future changes to on-disk directory layout: plan directory information REST API
• Bamboo Clover Plugin improvements

Read more in Bamboo 5.9 Release Notes.

For more information, see Bamboo upgrade guide.

Bamboo 5.8
17 March 2015
• Docker task for builds and deployments
• Improved integration with AWS
• Bamboo analytics added
• Support for Java 8
• Support for Java 7 is deprecated
• Support for Microsoft SQL Server 2005 and 2008 is deprecated
• Support for MySQL 5.1 is deprecated
• Support for PostgreSQL 8 is deprecated

Read more in the Bamboo 5.8 Release Notes.

See the Bamboo upgrade guide.

Bamboo 5.7
11 November 2014
• Control storage demands of deployment artifacts
• Take charge of build and release variables
• Manage remote Bamboo agents with Docker
• Use Bamboo with Node.js projects
• New Bamboo search tool for projects and plans
• Bamboo now supports Microsoft SQL Server 2012
• Support for Java 6 is deprecated
• Legacy Stash integration features removed

Read more in the Bamboo 5.7 Release Notes.

See the Bamboo upgrade guide.

Bamboo 5.6
29 July 2014
• Improved Stash integration:
  • Bamboo builds are triggered by Stash repo events
  • Bamboo plan branches update when branches are created or deleted in Stash
  • Bamboo build status is notified automatically to Stash
• Dedicated agents
• Clone deployment projects
• Deployments now appear in the activity streams for agents and builds
• Build queue improvements
• Project name is now editable
• The legacy Stash notifications and web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7.
Bamboo 5.5
28 April 2014
- Improved Stash integration
- Share repositories renamed to 'linked' repositories
- Stash legacy web repositories deprecated
- Bamboo menu layout change
- Subversion 1.8 is now supported
- Tomcat 5.5 and 6.0 are no longer supported.
- Internet Explorer 8 is no longer supported.

Read more in the Bamboo 5.5 release notes.
See the Bamboo upgrade guide.

Bamboo 5.4
11 February 2014
- Administration access navigation change
- Deployment workflow
- Deployment dashboard
- Reliability and stability
- Tomcat 5.5 and 6.0 deprecated.

Read more in the Bamboo 5.4 release notes.
See the Bamboo upgrade guide.

Bamboo 5.3
11 December 2013
- XSRF protection
- Deployment preview

Read more in the Bamboo 5.3 release notes.
See the Bamboo upgrade guide.

Bamboo 5.2
15 October 2013
- Branch deployments
- Advanced Gravatar support
- Branch checking interval editing

Read more in the Bamboo 5.2 release notes.
See the Bamboo upgrade guide.

Bamboo 5.1
13 September 2013
- Jira issue deployment reporting

Read more in the Bamboo 5.1 release notes.
See the Bamboo upgrade guide.

Bamboo 5.0
28 August 2013
- Deployment projects and environments
- Release versioning

Read more in the Bamboo 5.0 release notes.

See the Bamboo upgrade guide.

Bamboo 4.4

29 January 2013

- Jenkins importer
- Enhanced performance
- TestNG reports parser
- Selective task running
- Quick build number copying
- Server pausing

Read more in the Bamboo 4.4 release notes.

See the Bamboo upgrade guide.

Bamboo 4.3

30 October 2012

- Simple deployments to Tomcat
- Deploy to the Cloud with Heroku
- Upload files using SCP
- Build from any revision
- Runtime variables for Manual Stages
- Rebuild with one click
- Multiple build Triggers
- Build dependencies after all Stages
- Automatic dependencies for Maven 3
- Dashboard filtering
- Amazon Virtual Private Cloud for Elastic Bamboo
- Wallboard for Branches

Read more in the Bamboo 4.3 release notes.

See the Bamboo upgrade guide.

Bamboo 4.2

21 August 2012

- Notifications, build strategies and dependencies for plan branches
- Automatic linking of Jira issues to feature branches
- Bamboo build artifacts are linked from Jira issues
- Git support in the Bamboo Bitbucket connector
- Subversion 1.7 support
- UX improvements
- Mercurial commit isolation

Read more in the Bamboo 4.2 release notes.

See the Bamboo upgrade guide.

Bamboo 4.1

29 May 2012

- Get builds fixed faster with responsibilities
- Take action with Jira issue creation
- Get your team communicating with Hipchat notifications
- Welcome to the family, Stash!

Read more in the Bamboo 4.1 release notes.

See the Bamboo upgrade guide.
27 March 2012

- Automatically Build Branches
- Automatically Merge Branches using Gatekeeper and Branch Updater
- Manage Build Failures by Quarantining Intermittent Tests
- Fresh New User Experience

Read more in the Bamboo 4.0 release notes.
See the Bamboo upgrade guide.

Bamboo 3.4

14 December 2011

- Git Submodule Support
- Shared Repositories
- Agent Security Improvements
- New Email Templates
- Elastic Bamboo support for Microsoft Windows®

Read more in the Bamboo 3.4 release notes.
See the Bamboo upgrade guide.

Bamboo 3.3

11 October 2011

- Multiple Source Repositories
- Reload-able Plugins
- Source Repository User Aliases
- Automatic Agent Upgrades
- Fast, history-friendly tabbed navigation
- Commit Centric View

Read more in the Bamboo 3.3 release notes.
See the Bamboo upgrade guide.

Bamboo 3.2

26 July 2011

- Release Management
- Manual Stages
- Rerunning a Failed Stage
- Plan Filters on the Dashboard and Wallboard
- User Management via Jira
- Improved Application Linking

Read more in the Bamboo 3.2 release notes.
See the Bamboo upgrade guide.

Bamboo 3.1

10 May 2011

- Tasks
- Parameterized Builds
- .Net Support
- Bitbucket Support
- GitHub Support
- New Plugin Manager
- Support for Amazon EC2 Spot Instances
- Gravatar Support
- Improved Windows process handling

Read more in the Bamboo 3.1 release notes.
See the Bamboo upgrade guide.
Bamboo 3.0
16 February 2011

- Artifact Sharing
- Git Support
- User Interface Overhaul — Redesigned Plan Summary, Job Summary and Build Results. New look and feel.
- Scheduled Repository Polling
- Configuration Changes Captured in Audit Logs

Read more in the Bamboo 3.0 release notes.
See the Bamboo upgrade guide.

Bamboo 2.7
9 Nov 2010

- Build Stages — Map Your Build Process, Parallel Builds, Enhanced Plan Structure
- Simplified Plan Creation
- Concurrent Builds
- Mercurial Support
- Improved Wallboards
- New Plan and Job Configuration Summaries
- Recent History on Plan and Job Summaries
- Other User Interface Enhancements — New Breadcrumb Trail, Build Histories, Improved Build Result Summary Tabs

Read more in the Bamboo 2.7 release notes.
See the Bamboo upgrade guide.

Bamboo 2.6
1 June 2010

- Support for up to 100 Remote Agents
- Revamped Dashboard Pages and Other Usability Enhancements
- Performance and Security Improvements
- Automatically Managed Elastic Instances
- Grails Integration

Read more in the Bamboo 2.6 release notes.
See the Bamboo upgrade guide.

Bamboo 2.5
4 January 2010

- Maven Dependency Management
- Plan Import from a pom.xml
- Additional Bulk Actions
- Streamlined Plan Creation
- Express Setup Wizard

Read more in the Bamboo 2.5 release notes.
See the Bamboo upgrade guide.

Bamboo 2.4
6 October 2009

- Bamboo Gadgets in Jira
- Clover Enhancements
- REST Improvements
- Runtime Log4j Configuration

Read more in the Bamboo 2.4 release notes.
See the Bamboo upgrade guide.
Bamboo 2.3
6 August 2009
- Dependency Blocking Strategies
- New Build Notifications and Queue Reordering
- Bulk Actions
- Multiple Elastic Images
- Elastic Instance Scheduling
- PHPUnit Builder
- Bamboo REST APIs
- Plugins Changes

Read more in the Bamboo 2.3 release notes.
See the Bamboo upgrade guide.

Bamboo 2.2
9 March 2009
- Elastic Bamboo
- Customizable Email Templates
- Build Comment Notification Event
- Hanging Build Detection Event
- Faster Artifact Transfer
- Dependent Builds
- Agent Improvements

Read more in the Bamboo 2.2 release notes.
See the Bamboo upgrade guide.

Bamboo 2.1
5 August 2008
- Link Issues and Builds
- Specify the Issues that are Fixed by a Build
- Track the Builds for your Projects and Versions
- View Issues under Development
- Post Change Detection Plugin Point

Read more in the Bamboo 2.1 release notes.
See the Bamboo upgrade guide.

Bamboo 2.0
14 April 2008
- Distributed builds
- Capability matching
- Memory usage improvements
- Parallel VCS updates and checkouts
- Ability to force a ‘clean build’
- Quiet Period functionality supported for Subversion & Perforce
- Bamboo Plugin for Confluence
- Support for Oracle and MS SQL Server databases
- Status Summary screens

Read more in the Bamboo 2.0 release notes.
See the Bamboo upgrade guide.

Bamboo 1.2
09 July 2007
- Permissions (global and plan-based)
- External database support
- Perforce triggering support
- Scheduled backups
Changes to permissions

Bamboo 6.2 introduces multiple changes to permissions to make permissions management more transparent. Here’s a summary of these changes:

Project admin

We’ve created a new permission called Project admin allows Bamboo administrators to hand down some of their responsibilities for more effective management of the project. For instance, if Bamboo is used by 10 development teams, a global administrator can create 10 projects, one for each team, and delegate permissions management to team leaders by giving them the Project admin permissions. Users with the Project admin permissions can:
• manage permissions for the project
• manage permissions for all plans in a project
• change project settings

Create plan permission

The former "Create plan" global permission, now called Create, allows you to also create empty projects. Additionally, having the Create plan permission on a project-level already allows you to create new plans for that project even if you don't have the the global Create permission.

The already existing plan-level permissions (View, Edit, Build, Close, Admin) can now also be set on a project-level, which means that you will have them in all plans in your project. You can still set these permissions on the plan-level only just like before.

Permissions become additive

Once you're assigned permissions on any level, you'll automatically have permissions on lower levels. You can't override or remove permissions on lower levels. For example, if you have Create permission of a global level, you can create plans on all levels. Another example, if you have Build permission assigned to you on a project level and none assigned on the plan level explicitly, you will still have build permissions for that plan anyhow.

Projects menu

The new Projects menu lists all available projects together with their project codes, names and descriptions.

The project list, together with projects details, is available to everyone, who has access to this Bamboo instance including anonymous users when the anonymous access is enabled.

Artifact handlers

With Bamboo 6.2 artifact handlers Bamboo administrators can control where artifacts produced by plans are stored. This can help to optimize the utilization of network bandwidth and filesystem space. You can activate each handler for shared and non-shared artifacts separately. The default artifact handler selection is configured by Bamboo administrator but can be overridden in a plan's configuration by users that have administration permission on the plan.

To configure artifact handlers, go to Administration > Artifact handlers.

Types of handlers used by Bamboo:

AGENT-LOCAL ARTIFACT HANDLER

This handler stores the artifact on Bamboo's remote agent's filesystem. This handler does not publish artifacts to server (in other words, the artifacts will not be downloadable from result pages if remote or s3 handlers are not enabled). It can be used to save bandwidth when exchanging artifacts between builds & deployments running on the same agent or running on different agents that share common filesystem. In the configuration you need to define the root directory in which all the artifacts will be saved.

BAMBOO REMOTE HANDLER

This handler makes artifacts accessible on Bamboo remote and elastic agents. It also allows remote agents to publish artifacts they produce when running builds.

AMAZON S3
Artifacts are stored at Amazon S3 and are downloadable from there. Amazon S3 that offers unlimited flexible storage capacity. For more information about S3, see the Amazon S3 page. You can use the AWS credentials provided in the Elastic Bamboo configuration or you can configure separate account. In either case, you need to provide a bucket name. You can also (optionally) provide a root path for all the artifacts, which can come in handy if you use the same S3 bucket for other purposes. Lastly, you can define a maximum number of files per artifact; if this threshold is exceeded the artifact is automatically zipped into a single file, which reduces the number of requests to S3 when uploading and downloading the artifacts and improves the efficiency of the whole process.

**SERVER-LOCAL ARTIFACT HANDLER**

This handler stores the artifacts directly on Bamboo server's filesystem. It is used by Bamboo server itself and by local agents.

**Repository-stored Bamboo Specs**

6.2 release of Bamboo brings you possibility of storing your build plan configuration (Bamboo Specs) in your Bitbucket repository. Storing Bamboo Specs in a repository gives you access to history of plan specification, and makes it easy to revert to a particular moment in time. Additionally, by storing plans in repository users have not only information what changes were applied in the past, but also why they have been implemented this way giving them more context about the changes.

To allow Bamboo to scan a repository for Bamboo Specs, go to Administration > Linked repositories. In the Bamboo Specs tab, toggle Scan for Bamboo Specs.

**Support for Bitbucket Server Smart Mirroring**

Bamboo introduces support for the Bitbucket Server Smart Mirroring capability. Smart Mirroring allows you to use mirror locations for storing your repository data instead of using remote location. This way you can clone and fetch repositories from the mirror and get identical content, only faster.

Read more about all benefits of using Smart Mirroring in the Bitbucket Server documentation.

On Bamboo side, repository can be cloned from a selected mirror. Bamboo can also use mirrors for triggering builds. Whenever a mirror is synchronized with new changes, it sends an event to Bamboo and activates triggers on the affected repository.

**Requirements:**

- Bitbucket Server 5.0.0 or later
- Bitbucket Server Data Center license to support mirrors
- Routing from Bamboo to Stash and a selected mirror enabled.
- Routing between agent and mirror enabled.

Downgrading from Bitbucket Server Data Center license to a regular license may cause problems. In the unlikely event of such a downgrade, we recommend to switch all repositories to primary before switching versions.

Downgrading from Bitbucket Server Data Center from version 5+ to version 4 may cause problems. In the unlikely event of such a downgrade, we recommend to switch all repositories to primary before switching versions.
**Bamboo 6.2 EAP Release Notes v6.1**

We are proud to present **Bamboo 6.2 EAP**. This release is part of our Early Access Program (EAP) leading up to the official **Bamboo 6.2** release. We are making these EAP milestones publicly available so that developers can start assessing the impact of the changes that we are making.

**Important**

Development releases are snapshots of the ongoing Bamboo development process. For that reason:

- While we try to keep these releases stable, they have not undergone the same degree of testing as a full release.
- Features in development releases may be incomplete, or may change or be removed before the next full release.

Much as you are able to upgrade previous versions of Bamboo to the 6.2 EAP version, and smoothly upgrade from the 6.2 EAP to the final version, once it's released, we don't recommend installing the EAP release on your current production environment. For information about the supported upgrade paths, see **Bamboo upgrade guide**.

**Atlassian does not provide support for development releases.**

---

**Changes in permissions**

Bamboo 6.2 introduces multiple changes to permissions to make permissions management more transparent. Here's a summary of these changes:

**Permissions become additive**

Once you're assigned permissions on any level, you'll automatically have permissions on lower levels. You can’t override or remove permissions on lower levels. For example, if you have Create permission of a global level, you can create plans on all levels. Another example, if you have Build permission assigned to you on a project level and none assigned on the plan level explicitly, you will still have build permissions for that plan anyhow.

**Project admin**

We’ve created a new permission called **Project admin**, which allows Bamboo administrators to hand down some of their responsibilities for more effective management of the project. For instance, if Bamboo is used by 10 development teams, a global administrator can create 10 projects, one for each team, and delegate permissions management to team leaders by giving them the **Project admin** permissions. Users with the **Project admin** permissions can:

- manage permissions for the project
- manage permissions for all plans in a project
- change project settings

**Create plan permission**

The former ”Create plan” global permission, now called **Create**, allows you to also create empty projects. Additionally, having the **Create plan** permission on a project-level already allows you to create new plans for that project even if you don't have the global **Create** permission.

The already existing plan-level permissions (View, Edit, Build, Close, Admin) can now also be set on a project-level, which means that you will have them in all plans in your project. You can still set these permissions on the plan-level only just like before.

**Projects menu**

The new **Projects** menu lists all available projects together with their project codes, names and descriptions.

The project list, together with projects details, is available to everyone who has access to this Bamboo instance including anonymous users when the anonymous access is enabled.
Artifact handlers allow Bamboo administrators to control where artifacts produced by plans are stored. This can help to optimize the utilization of network bandwidth and filesystem space. You can activate each handler for shared and non-shared artifacts separately. The default artifact handler selection is configured by Bamboo administrator but can be overridden in a plan's configuration by users that have administration permission on the plan.

To configure artifact handlers, go to Administration > Artifact handlers.

Types of handlers used by Bamboo:

**Agent-local artifact handler**
This handler stores the artifact on Bamboo's remote agent's filesystem. This handler does not publish artifacts to server (in other words, the artifacts will not be downloadable from result pages if remote or s3 handlers are not enabled). It can be used to save bandwidth when exchanging artifacts between builds & deployments running on the same agent or running on different agents that share a common filesystem. In the configuration you need to define the root directory in which all the artifacts will be saved.

**Bamboo remote handler**
This handler makes artifacts accessible on Bamboo remote and elastic agents. It also allows remote agents to publish artifacts they produce when running builds.

**Amazon S3**
Artifacts are stored at Amazon S3 and are downloadable from there. Amazon S3 that offers unlimited flexible storage capacity. For more information about S3, see the Amazon S3 page. You can use the AWS credentials provided in the Elastic Bamboo configuration or you can configure a separate account. In either case, you need to provide a bucket name. You can also (optionally) provide a root path for all the artifacts, which can come in handy if you use the same S3 bucket for other purposes. Lastly, you can define a maximum number of files per artifact; if this threshold is exceeded the artifact is automatically zipped into a single file, which reduces the number of requests to S3 when uploading and downloading the artifacts and improves the efficiency of the whole process.

**Server-local artifact handler**
This handler stores the artifacts directly on Bamboo server's filesystem. It is used by Bamboo server itself and by local agents.

**Repository-stored Bamboo Specs**

6.2 release of Bamboo brings you possibility of storing your build plan configuration (Bamboo Specs) in your Bitbucket repository. Storing Bamboo Specs in a repository gives you access to history of plan specification, and makes it easy to revert to a particular moment in time. Additionally, by storing plans in repository users have not only information what changes were applied in the past, but also why they have been implemented this way giving them more context about the changes.

To allow Bamboo to scan a repository for Bamboo Specs, go to Administration > Linked repositories. In the Bamboo Specs tab, toggle Scan for Bamboo Specs.
We've also added a new icon to the build history to help you identify the Bamboo Specs errors.

**Performance and scalability improvements**

**Changes to permissions**

Bamboo 6.2 introduces multiple changes to permissions to make permissions management more transparent. Here's a summary of these changes:

**Project admin**

We've created a new permission called Project admin allows Bamboo administrators to hand down some of their responsibilities for more effective management of the project. For instance, if Bamboo is used by 10 development teams, a global administrator can create 10 projects, one for each team, and delegate permissions management to team leaders by giving them the Project admin permissions. Users with the Project admin permissions can:

- manage permissions for the project
- manage permissions for all plans in a project
• change project settings

Create plan permission

The former "Create plan" global permission, now called Create, allows you to also create empty projects. Additionally, having the Create plan permission on a project-level already allows you to create new plans for that project even if you don't have the the global Create permission.

The already existing plan-level permissions (View, Edit, Build, Close, Admin) can now also be set on a project-level, which means that you will have them in all plans in your project. You can still set these permissions on the plan-level only just like before.

Permissions become additive

Once you’re assigned permissions on any level, you’ll automatically have permissions on lower levels. You can’t override or remove permissions on lower levels. For example, if you have Create permission of a global level, you can create plans on all levels. Another example, if you have Build permission assigned to you on a project level and none assigned on the plan level explicitly, you will still have build permissions for that plan anyhow.

Projects menu

The new Projects menu lists all available projects together with their project codes, names and descriptions.

The project list, together with projects details, is available to everyone, who has access to this Bamboo instance including anonymous users when the anonymous access is enabled.

Artifact handlers

With Bamboo 6.2 artifact handlers Bamboo administrators can control where artifacts produced by plans are stored. This can help to optimize the utilization of network bandwith and filesystem space. You can activate each handler for shared and non-shared artifacts separately. The default artifact handler selection is configured by Bamboo administrator but can be overridden in a plan’s configuration by users that have administration permission on the plan.

To configure artifact handlers, go to Administration > Artifact handlers.

Types of handlers used by Bamboo:

AGENT-LOCAL ARTIFACT HANDLER

This handlers stores the artifact on Bamboo's remote agent's filesystem. This handler does not publish artifacts to server (in other words, the artifacts will not be downloadable from result pages if remote or s3 handlers are not enabled). It can be used to save bandwidth when exchanging artifacts between builds & deployments running on the same agent or running on different agents that share common filesystem. In the configuration you need to define the root directory in which all the artifacts will be saved.

BAMBOO REMOTE HANDLER

This handler makes artifacts accessible on Bamboo remote and elastic agents. It also allows remote agents to publish artifacts they produce when running builds.

AMAZON S3

Artifacts are stored at Amazon S3 and are downloadable from there. Amazon S3 that offers unlimited flexible storage capacity. For more information about S3, see the Amazon S3 page. You can use the AWS credentials provided in the Elastic Bamboo configuration or you can configure separate account. In either case, you need to provide a bucket name. You can also (optionally) provide a root path for all the artifacts, which can come in handy if you use the same S3 bucket for other purposes. Lastly, you can define a maximum number of files per artifact; if this threshold is exceeded the artifact is automatically zipped into a single file, which reduces the number of requests to S3 when uploading and downloading the artifacts and improves the efficiency of the whole process.
SERVER-LOCAL ARTIFACT HANDLER
This handler stores the artifacts directly on Bamboo server's filesystem. It is used by Bamboo server itself and by local agents.

Repository-stored Bamboo Specs
6.2 release of Bamboo brings you possibility of storing your build plan configuration (Bamboo Specs) in your Bitbucket repository. Storing Bamboo Specs in a repository gives you access to history of plan specification, and makes it easy to revert to a particular moment in time. Additionally, by storing plans in repository users have not only information what changes were applied in the past, but also why they have been implemented this way giving them more context about the changes.

To allow Bamboo to scan a repository for Bamboo Specs, go to Administration > Linked repositories. In the Bamboo Specs tab, toggle Scan for Bamboo Specs.

Linked repositories
Repositories defined here are available to every plan. You can select these repositories in plans configuration. Changes to them will be applied to every plan that uses them.

We've also added a new icon to the build history to help you identify the Bamboo Specs errors.

Support for Bitbucket Server Smart Mirroring
Bamboo introduces support for the Bitbucket Server Smart Mirroring capability. Smart Mirroring allows you to use mirror locations for storing your repository data instead of using remote location. This way you can clone and fetch repositories from the mirror and get identical content, only faster.

Read more about all benefits of using Smart Mirroring in the Bitbucket Server documentation.

On Bamboo side, repository can be cloned from a selected mirror. Bamboo can also use mirrors for triggering builds. Whenever a mirror is synchronized with new changes, it sends an event to Bamboo and activates triggers on the affected repository.

Requirements:
- Bitbucket Server 5.0.0 or later
- Bitbucket Server Data Center license to support mirrors
- Routing from Bamboo to Stash and a selected mirror enabled.
- Routing between agent and mirror enabled.

Downgrading from Bitbucket Server Data Center license to a regular license may cause problems. In the unlikely event of such a downgrade, we recommend to switch all repositories to primary before switching versions.

Downgrading from Bitbucket Server Data Center from version 5+ to version 4 may cause problems. In the unlikely event of such a downgrade, we recommend to switch all repositories to primary before switching versions.

.Bamboo 6.2 EAP Release Notes v6.3
We are proud to present Bamboo 6.2 EAP. This release is part of our Early Access Program (EAP) leading up to the official Bamboo 6.2 release. We are making these EAP milestones publicly available so that developers can start assessing the impact of the changes that we are making.

**Changes to permissions**

Bamboo 6.2 introduces multiple changes to permissions to make permissions management more transparent. Here's a summary of these changes:

**Project admin**

We've created a new permission called **Project admin** allows Bamboo administrators to hand down some of their responsibilities for more effective management of the project. For instance, if Bamboo is used by 10 development teams, a global administrator can create 10 projects, one for each team, and delegate permissions management to team leaders by giving them the **Project admin** permissions. Users with the **Project admin** permissions can:

- manage permissions for the project
- manage permissions for all plans in a project
- change project settings

**Create plan permission**

The former "Create plan" global permission, now called **Create**, allows you to also create empty projects. Additionally, having the **Create** permission on a project-level already allows you to create new plans for that project even if you don't have the global **Create** permission.

The already existing plan-level permissions (**View**, **Edit**, **Build**, **Close**, **Admin**) can now also be set on a project-level, which means that you will have them in all plans in your project. You can still set these permissions on the plan-level only just like before.

**Permissions become additive**

Once you're assigned permissions on any level, you'll automatically have permissions on lower levels. You can't override or remove permissions on lower levels. For example, if you have **Create** permission of a global level, you can create plans on all levels. Another example, if you have **Build** permission assigned to you on a project level and none assigned on the plan level explicitly, you will still have build permissions for that plan anyhow.

**Projects menu**

The new **Projects** menu lists all available projects together with their project codes, names and descriptions.

The project list, together with projects details, is available to everyone, who has access to this Bamboo instance including anonymous users when the anonymous access is enabled.
Artifact handlers

With Bamboo 6.2 artifact handlers Bamboo administrators can control where artifacts produced by plans are stored. This can help to optimize the utilization of network bandwidth and filesystem space. You can activate each handler for shared and non-shared artifacts separately. The default artifact handler selection is configured by Bamboo administrator but can be overridden in a plan’s configuration by users that have administration permission on the plan.

To configure artifact handlers, go to [Administration > Artifact handlers](Administration-Artifact-handlers).

Types of handlers used by Bamboo:

**AGENT-LOCAL ARTIFACT HANDLER**

This handler stores the artifact on Bamboo's remote agent's filesystem. This handler does not publish artifacts to server (in other words, the artifacts will not be downloadable from result pages if remote or s3 handlers are not enabled). It can be used to save bandwidth when exchanging artifacts between builds & deployments running on the same agent or running on different agents that share common filesystem. In the configuration you need to define the root directory in which all the artifacts will be saved.

**BAMBOO REMOTE HANDLER**

This handler makes artifacts accessible on Bamboo remote and elastic agents. It also allows remote agents to publish artifacts they produce when running builds.

**AMAZON S3**

Artifacts are stored at Amazon S3 and are downloadable from there. Amazon S3 that offers unlimited flexible storage capacity. For more information about S3, see the Amazon S3 page. You can use the AWS credentials provided in the Elastic Bamboo configuration or you can configure separate account. In either case, you need to provide a bucket name. You can also (optionally) provide a root path for all the artifacts, which can come in handy if you use the same S3 bucket for other purposes. Lastly, you can define a maximum number of files per artifact; if this threshold is exceeded the artifact is automatically zipped into a single file, which reduces the number of requests to S3 when uploading and downloading the artifacts and improves the efficiency of the whole process.

**SERVER-LOCAL ARTIFACT HANDLER**

This handler stores the artifacts directly on Bamboo server's filesystem. It is used by Bamboo server itself and by local agents.

Repository-stored Bamboo Specs

6.2 release of Bamboo brings you possibility of storing your build plan configuration (Bamboo Specs) in your Bitbucket repository. Storing Bamboo Specs in a repository gives you access to history of plan specification, and makes it easy to revert to a particular moment in time. Additionally, by storing plans in repository users have not only information what changes were applied in the past, but also why they have been implemented this way giving them more context about the changes.

To allow Bamboo to scan a repository for Bamboo Specs, go to [Administration > Linked repositories](Administration-Linked-repositories). In the Bamboo Specs tab, toggle [Scan for Bamboo Specs](Scan-for-Bamboo-Specs).
We've also added a new icon to the build history to help you identify the Bamboo Specs errors.

**Support for Bitbucket Server Smart Mirroring**

Bamboo introduces support for the Bitbucket Server Smart Mirroring capability. Smart Mirroring allows you to use mirror locations for storing your repository data instead of using remote location. This way you can clone and fetch repositories from the mirror and get identical content, only faster.

Read more about all benefits of using Smart Mirroring in the Bitbucket Server documentation.

On Bamboo side, repository can be cloned from a selected mirror. Bamboo can also use mirrors for triggering builds. Whenever a mirror is synchronized with new changes, it sends an event to Bamboo and activates triggers on the affected repository.

**Requirements:**

- Bitbucket Server 5.0.0 or later
- Bitbucket Server Data Center license to support mirrors
- Routing from Bamboo to Stash and a selected mirror enabled.
- Routing between agent and mirror enabled.

Downgrading from Bitbucket Server Data Center license to a regular license may cause problems. In the unlikely event of such a downgrade, we recommend to switch all repositories to primary before switching versions.

Downgrading from Bitbucket Server Data Center from version 5+ to version 4 may cause problems. In the unlikely event of such a downgrade, we recommend to switch all repositories to primary before switching versions.

**Bamboo 6.3 Release Notes**

**December 2017**

The Atlassian Bamboo team is proud to release Bamboo 6.3. If you're upgrading, read the Bamboo upgrade guide.

Get the latest version
Bamboo YAML Specs

Create simple plans using Bamboo YAML Specs in no time.

As an alternative to using Bamboo Java Specs, Bamboo 6.3 allows you to create simple plans using Bamboo YAML Specs in no time. Just use one of the templates we provide and you’re ready to start committing your files to a repository.

To learn more about this feature, see Bamboo YAML documentation. We’ve also prepared a number of templates that you can use in our Bamboo YAML reference.
New repository-stored Bamboo Specs protection

You can now process repository-stored Bamboo Specs in a Docker container for extra security. Docker gives you an opportunity of running builds in an isolated environment available only for the duration of the build. Bamboo 6.3 is shipped with a Docker image that contains all required dependencies.

Bamboo 6.3 adds new permission controls for linked repositories. User is now able to choose what RSS repository can use a given repository or grant all repositories access for RSS repository.

In case build plan or deployment project try to use repository which was not granted these permissions, a build will fail and user will get information in RSS logs that repository usage is not allowed.

Branching with multiple repositories

This highly-anticipated feature allows you to change individual branches for all repositories in your plan, regardless whether the branch was created manually or automatically. In Bamboo 6.3 you will also be able to override any repository settings such as repository location, which might come in handy in case your development workflow uses forks rather than branches. To learn more, check out Using plan branches.

To make your life easier, we’ve also added a quick overview of repositories and branches used in the plan - the ‘Repository branches’ on the ‘Branch details’ tab.

Cleaning up permission dependencies

To ensure the consistency of Bamboo permissions, starting with Bamboo 6.3, we provide an update mechanism which will fix all inconsistencies for all permissions in your Bamboo environment. We have also modified all the pages where you can edit permissions in a way that won’t allow granting inconsistent or clashing permissions in the future.

From now on, if you want to revoke a lower-level permission for a user, you must revoke the higher-level permissions first. Also, when granting a higher-level permission to a user, all relevant lower-level permissions will be granted automatically to that user.

Nested variables

Starting from version 6.3, Bamboo is able to pick up your variables from all fields of a task or deployment. You can find everything you want to know about variables in Bamboo in our documentation.

Git authentication more secure

For any Git operation that require authentication, Bamboo 6.3 introduced new way of storing your credentials. Your user name and password are now kept in a temporary file created by Bamboo. Once authenticated, Bamboo deletes the file with your credentials.

Bug fixes and improvement

You can view the detailed list of other fixed bugs at the bottom of this page.

Known issues

Here’s a list of known issues in this release that might affect you, depending on your environment. Every deployment is unique, so we are listing the issues here to help you make an informed decision about upgrading.
We continue to work on resolving these issues. ETA for some of these fixes can be seen in the “Fix version” column.

**Bamboo 6.3 Release Notes v6.3**

December 2017

The Atlassian Bamboo team is proud to release Bamboo 6.3. If you’re upgrading, read the Bamboo upgrade guide.

Get the latest version

---

**Bamboo YAML Specs**
Bamboo YAML Specs
Create simple plans using Bamboo YAML Specs in no time.

As an alternative to using Bamboo Java Specs, Bamboo 6.3 allows you to create simple plans using Bamboo YAML Specs in no time. Just use one of the templates we provide and you’re ready to start committing your files to a repository.

To learn more about this feature, see Bamboo YAML documentation. We’ve also prepared a number of templates that you can use in our Bamboo YAML reference.

New repository-stored Bamboo Specs protection

You can now process repository-stored Bamboo Specs in a Docker container for extra security. Docker gives you an opportunity of running builds in an isolated environment available only for the duration of the build. Bamboo 6.3 is shipped with a Docker image that contains all required dependencies.

Bamboo 6.3 adds new permission controls for linked repositories. User is now able to choose what RSS repository can use a given repository or grant all repositories access for RSS repository.

In case build plan or deployment project try to use repository which was not granted these permissions, a build will fail and user will get information in RSS logs that repository usage is not allowed.

Branching with multiple repositories

This highly-anticipated feature allows you to change individual branches for all repositories in your plan, regardless whether the branch was created manually or automatically. In Bamboo 6.3 you will also be able to override any repository settings such as repository location, which might come in handy in case your development workflow uses forks rather than branches. To learn more, check out Using plan branches.
To make your life easier, we’ve also added a quick overview of repositories and branches used in the plan - the ‘Repository branches’ on the ‘Branch details’ tab.

Cleaning up permission dependencies

To ensure the consistency of Bamboo permissions, starting with Bamboo 6.3, we provide an update mechanism which will fix all inconsistencies for all permissions in your Bamboo environment. We have also modified all the pages where you can edit permissions in a way that won’t allow granting inconsistent or clashing permissions in the future.

From now on, if you want to revoke a lower-level permission for a user, you must revoke the higher-level permissions first. Also, when granting a higher-level permission to a user, all relevant lower-level permissions will be granted automatically to that user.

Nested variables

Starting from version 6.3, Bamboo is able to pick up your variables from all fields of a task or deployment. You can find everything you want to know about variables in Bamboo in our documentation.

Git authentication more secure

For any Git operation that require authentication, Bamboo 6.3 introduced new way of storing your credentials. Your user name and password are now kept in a temporary file created by Bamboo. Once authenticated, Bamboo deletes the file with your credentials.

Bug fixes and improvement

You can view the detailed list of other fixed bugs at the bottom of this page.

Known Issues

Here’s a list of known issues in this release that might affect you, depending on your environment. Every deployment is unique, so we are listing the issues here to help you make an informed decision about upgrading.

We continue to work on resolving these issues. ETA for some of these fixes can be seen in the “Fix version” column.

Bamboo 6.3 EAP Release Notes

We are proud to present Bamboo 6.3 EAP. This release is part of our Early Access Program (EAP) leading up to the official Bamboo 6.3 release. We are making these EAP milestones publicly available so that developers can start assessing the impact of the changes that we are making.
Important

Development releases are snapshots of the ongoing Bamboo development process. For that reason:

- While we try to keep these releases stable, they have not undergone the same degree of testing as a full release.
- Features in development releases may be incomplete, or may change or be removed before the next full release.

Much as you are able to upgrade previous versions of Bamboo to the 6.3 EAP version, and smoothly upgrade from the 6.3 EAP to the final version, once it’s released, we don’t recommend installing the EAP release on your current production environment. For information about the supported upgrade paths, see Bamboo upgrade guide.

Atlassian does not provide support for development releases.

Bamboo YAML Specs

Bamboo YAML Specs
Create simple plans using Bamboo YAML Specs in no time.
As an alternative to using Bamboo Java Specs, Bamboo 6.3 allows you to create simple plans using Bamboo YAML Specs in no time. Just use one of the templates we provide and you’re ready to start committing your files to a repository.

To learn more about this feature, see Bamboo YAML Specs. We’ve also prepared a number of templates that you can use in our Bamboo YAML reference.

Branching with multiple repositories

This highly-anticipated feature allows you to change individual branches for all repositories in your plan, regardless whether the branch was created manually or automatically. In Bamboo 6.3 you will also be able to override any repository settings such as repository location, which might come in handy in case your development workflow uses forks rather than branches.

To make your life easier, we’ve also added a quick overview of repositories and branches used in the plan - the ‘Repository branches’ on the ‘Branch details’ tab:

Cleaning up permission dependencies

To ensure the consistency of Bamboo permissions, starting with Bamboo 6.3, we provide an update mechanism which will fix all inconsistencies for all permissions in your Bamboo environment. We have also modified all the pages where you can edit permissions in a way that won’t allow granting inconsistent or clashing permissions in the future.

From now on, if you want to revoke a lower-level permission for a user, you must revoke the higher-level permissions first. Also, when granting a higher-level permission to a user, all relevant lower-level permissions will be granted automatically to that user.

.Bamboo 6.3 EAP Release Notes v6.3

We are proud to present Bamboo 6.3 EAP. This release is part of our Early Access Program (EAP) leading up to the official Bamboo 6.3 release. We are making these EAP milestones publicly available so that developers can start assessing the impact of the changes that we are making.

**Docker Runner**

A complaint we often heard from teams using Bamboo was that there's limited self service in agent capability management: in order to install new tooling, one needed administrative privileges on the agent or the agent had to be to run with administrator rights (to install dependencies during build). Neither option was ideal: the former incurred administrative overhead, the latter was risky and would likely cause problems for subsequent builds running on the same agent.

With Bamboo 6.4, you can decide to run the build (or deployment) in a Docker container. This allows you to isolate the build process from the environment it runs in. There are several benefits to doing that:

- Increased security: you have strict control over resources the continuous integration (CI) process has access to,
- Improved CI reliability through isolation: the environment used to run the build/deployment is recreated and destroyed each time you run your builds - there are no stale files or processes left behind once the build is finished,
- Self service: additional dependencies can be installed during the build with no impact on subsequent builds.

If you want to learn more about Docker Runner, see our documentation.

---

**Force-stop your hanging builds**

Build monitoring mechanism of the Hung Build Killer plugin becomes native in Bamboo 6.4. This mechanism allows you to automatically stop any builds which, based on the criteria you set, are considered hanging.

Force-stop builds configuration applies globally. To overwrite its functionalities on lower levels, you can do it from the plan-level
To disable or change default Bamboo build monitoring settings, just go to

> Overview > Build Monitoring.

Build monitoring

Based on your settings Bamboo can define if build is hanging or timed out. You can override these settings for individual plans in the executable configuration of each plan.

- Allow Bamboo to detect hanging builds.

**Default settings**

Bamboo marks a build as hanging when both the expected build time and log quiet time values are exceeded. It can also flag your build as being too long if the build queue timeout value is exceeded.

<table>
<thead>
<tr>
<th>Build time multiplier</th>
<th>2.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log quiet time</td>
<td>20</td>
</tr>
<tr>
<td>Build queue timeout</td>
<td>45</td>
</tr>
</tbody>
</table>

- Force stop hanging builds and clean up sub-processes

**Bug fixes and improvement**

You can view the detailed list of other fixed bugs at the bottom of this page.

.Bamboo 6.4 Release Notes v6.5
February 2018

The Atlassian Bamboo team is proud to release Bamboo 6.4. If you're upgrading, read the Bamboo upgrade guide.

Get the latest version

---

**Docker Runner**

With Bamboo 6.4, you can decide to run the build (or deployment) in a Docker container. This allows you to isolate the build process from the environment it runs in. There are several benefits to doing that:

- **Increased security:** you have strict control over resources the continuous integration (CI) process has access to,
- **Improved CI reliability through isolation:** the environment used to run the build/deployment is recreated and destroyed each time you run your builds - there are no stale files or processes left behind once the build is finished,

Created by Atlassian in 2018. Licensed under a [Creative Commons Attribution 2.5 Australia License](https://creativecommons.org/licenses/by/2.5/au/).
Self service: additional dependencies can be installed during the build with no impact on subsequent builds.

If you want to learn more about Docker Runner, see our documentation.

---

**Force-stop your hanging builds**

Build monitoring mechanism of the Hung Build Killer plugin becomes native in Bamboo 6.4. This mechanism allows you to automatically stop any builds which, based on the criteria you set, are considered hanging.

Force-stop builds configuration applies globally. To overwrite its functionalities on lower levels, you can do it from the plan-level configuration.

To disable or change default Bamboo build monitoring settings, just go to

> Overview > Build Monitoring.

---

**Bug fixes and improvement**

You can view the detailed list of other fixed bugs at the bottom of this page.

Changelog

20 February 2017 - Bamboo 6.4
Bamboo releases v6.4

The following pages can be found in the latest documentation for Bamboo:

- the Bamboo upgrade guide
- the Bamboo security advisories
- the End of support announcements for Bamboo
- the full release notes for every Bamboo release.

You can get automated notifications about major Bamboo releases by subscribing to the Atlassian blog.

The list below is a summary of the Bamboo releases. The changelogs included in the release notes (linked below) have details of the related bug-fix releases.

**Bamboo 6.7**

October 2018

- Parsing build warnings
- New VCS tasks
- Welcome IPv6
- Bamboo Docker images

- Deployment project configuration now in audit log

For more information, see Bamboo 6.7 Release Notes

**Bamboo 6.6**

June 2018

- Embedded Crowd

For more information, see Bamboo 6.6 Release Notes.

**Bamboo 6.5**

24 April 2018

- Bamboo Specs run on new repos
- Bamboo gets a new logo
For more information, see Bamboo 6.5 Release Notes.

**Bamboo 6.4**

21 February 2018

- Docker Runner
- Force-stop hanging builds

For more information, see Bamboo 6.4 Release Notes.

**Bamboo 6.3**

20 December 2017

- Bamboo YAML Specs
- New repository-stored Bamboo Specs protection
- Branching with multiple repositories
- Cleaning up permissions dependencies
- Nested variables

For more information, see Bamboo 6.3 Release Notes.

**Bamboo 6.2**

28 September 2017

- Changes to permissions
- Artifact handler
- Repository-stored Bamboo Specs
- Support for Bitbucket Server Smart Mirroring
- Bamboo YAML

For more information, see Bamboo 6.2 Release Notes.

**Bamboo 6.1**

20 July 2017

- Improvements to Bamboo Specs for plans
- Bamboo Specs for Deployments

For more information, see Bamboo 6.1 Release Notes.

**Bamboo 6.0**

26 April 2017

- Configuration as Code
- SQL Server JDBC driver update
- Pull request in the branch status page
- Fastlane and Xcode support

For more information, see Bamboo 6.0 Release Notes.

**Bamboo 5.15**

14 February 2017

- Git LFS support
- System-wide encryption
- Improvements to the Branch Status page
- Spring Scanner 2 support

For more information, see Bamboo 5.15 Release Notes.
Bamboo 5.14

27 October 2016

- Platform upgrades
- New Branch status page
- Build plans and deployment projects in YAML (beta)
- Override of repository settings for plan branches
- Enhancements for Subversion repository configuration
- New API for VCS repositories
- Bug fixes

For more information, see Bamboo 5.14 Release Notes.

Bamboo 5.13

24 August 2016

- Platform upgrades
- Deployment requirements
- SSH support for Bitbucket Cloud
- Improvements for the script task
- Absolute paths for artifacts
- Bug fixes
- API changes

For more information, see Bamboo 5.13 Release Notes.

Bamboo 5.12

24 May 2016

- Platform upgrades
- Quick Filters
- User deactivation directly from Bamboo
- Bug fixes

For more information, see Bamboo 5.12 Release Notes.

Bamboo 5.11

26 April 2016

- Platform upgrades
- Application Links upgrade to version 5.0.7
- Bamboo Instance Health check
- New Create repository permission
- REST API deployment triggers

For more information, see Bamboo 5.11 Release Notes.

Bamboo 5.10

19 January 2016

- Platform upgrades
- Bamboo build status for Bitbucket

For more information, see Bamboo 5.10 Release Notes.

Bamboo 5.9

11 June 2015

- Improved automatic branch management
- Improved Docker task customization
- AWS Code Deploy task for Bamboo
- Easier shared credentials management
- Future changes to on-disk directory layout: plan directory information REST API
- Bamboo Clover Plugin improvements
Read more in Bamboo 5.9 Release Notes.

For more information, see Bamboo upgrade guide.

**Bamboo 5.8**

17 March 2015

- Docker task for builds and deployments
- Improved integration with AWS
- Bamboo analytics added
- Support for Java 8
- Support for Java 7 is deprecated
- Support for Microsoft SQL Server 2005 and 2008 is deprecated
- Support for MySQL 5.1 is deprecated
- Support for PostgreSQL 8 is deprecated

Read more in the Bamboo 5.8 Release Notes.

See the Bamboo upgrade guide.

**Bamboo 5.7**

11 November 2014

- Control storage demands of deployment artifacts
- Take charge of build and release variables
- Manage remote Bamboo agents with Docker
- Use Bamboo with Node.js projects
- New Bamboo search tool for projects and plans
- Bamboo now supports Microsoft SQL Server 2012
- Support for Java 6 is deprecated
- Legacy Stash integration features removed

Read more in the Bamboo 5.7 Release Notes.

See the Bamboo upgrade guide.

**Bamboo 5.6**

29 July 2014

- Improved Stash integration:
  - Bamboo builds are triggered by Stash repo events
  - Bamboo plan branches update when branches are created or deleted in Stash
  - Bamboo build status is notified automatically to Stash
- Dedicated agents
- Clone deployment projects
- Deployments now appear in the activity streams for agents and builds
- Build queue improvements
- Project name is now editable
- The legacy Stash notifications and web repository type are deprecated in Bamboo 5.6, and will be removed in Bamboo 5.7.

Read more in the Bamboo 5.6 Release Notes.

See the Bamboo upgrade guide.

**Bamboo 5.5**

28 April 2014

- Improved Stash integration
- Share repositories renamed to 'linked' repositories
- Stash legacy web repositories deprecated
- Bamboo menu layout change
- Subversion 1.8 is now supported
- Tomcat 5.5 and 6.0 are no longer supported.
- Internet Explorer 8 is no longer supported.

Read more in the Bamboo 5.5 release notes.

See the Bamboo upgrade guide.
Bamboo 5.4

11 February 2014

- Administration access navigation change
- Deployment workflow
- Deployment dashboard
- Reliability and stability
- Tomcat 5.5 and 6.0 deprecated.

Read more in the Bamboo 5.4 release notes.

See the Bamboo upgrade guide.

Bamboo 5.3

11 December 2013

- XSRF protection
- Deployment preview

Read more in the Bamboo 5.3 release notes.

See the Bamboo upgrade guide.

Bamboo 5.2

15 October 2013

- Branch deployments
- Advanced Gravatar support
- Branch checking interval editing

Read more in the Bamboo 5.2 release notes.

See the Bamboo upgrade guide.

Bamboo 5.1

13 September 2013

- Jira issue deployment reporting

Read more in the Bamboo 5.1 release notes.

See the Bamboo upgrade guide.

Bamboo 5.0

28 August 2013

- Deployment projects and environments
- Release versioning

Read more in the Bamboo 5.0 release notes.

See the Bamboo upgrade guide.

Bamboo 4.4

29 January 2013

- Jenkins importer
- Enhanced performance
- TestNG reports parser
- Selective task running
- Quick build number copying
- Server pausing

Read more in the Bamboo 4.4 release notes.

See the Bamboo upgrade guide.
Bamboo 4.3
30 October 2012

- Simple deployments to Tomcat
- Deploy to the Cloud with Heroku
- Upload files using SCP
- Build from any revision
- Runtime variables for Manual Stages
- Rebuild with one click
- Multiple build Triggers
- Build dependencies after all Stages
- Automatic dependencies for Maven 3
- Dashboard filtering
- Amazon Virtual Private Cloud for Elastic Bamboo
- Wallboard for Branches

Read more in the Bamboo 4.3 release notes.

See the Bamboo upgrade guide.

Bamboo 4.2
21 August 2012

- Notifications, build strategies and dependencies for plan branches
- Automatic linking of Jira issues to feature branches
- Bamboo build artifacts are linked from Jira issues
- Git support in the Bamboo Bitbucket connector
- Subversion 1.7 support
- UX improvements
- Mercurial commit isolation

Read more in the Bamboo 4.2 release notes.

See the Bamboo upgrade guide.

Bamboo 4.1
29 May 2012

- Get builds fixed faster with responsibilities
- Take action with Jira issue creation
- Get your team communicating with Hipchat notifications
- Welcome to the family, Stash!

Read more in the Bamboo 4.1 release notes.

See the Bamboo upgrade guide.

Bamboo 4.0
27 March 2012

- Automatically Build Branches
- Automatically Merge Branches using Gatekeeper and Branch Updater
- Manage Build Failures by Quarantining Intermittent Tests
- Fresh New User Experience

Read more in the Bamboo 4.0 release notes.

See the Bamboo upgrade guide.

Bamboo 3.4
14 December 2011

- Git Submodule Support
- Shared Repositories
- Agent Security Improvements
- New Email Templates
- Elastic Bamboo support for Microsoft Windows®
Bamboo 3.3

11 October 2011

- Multiple Source Repositories
- Reload-able Plugins
- Source Repository User Aliases
- Automatic Agent Upgrades
- Fast, history-friendly tabbed navigation
- Commit Centric View

Read more in the Bamboo 3.3 release notes.
See the Bamboo upgrade guide.

Bamboo 3.2

26 July 2011

- Release Management
- Manual Stages
- Rerunning a Failed Stage
- Plan Filters on the Dashboard and Wallboard
- User Management via Jira
- Improved Application Linking

Read more in the Bamboo 3.2 release notes.
See the Bamboo upgrade guide.

Bamboo 3.1

10 May 2011

- Tasks
- Parameterized Builds
- .Net Support
- Bitbucket Support
- GitHub Support
- New Plugin Manager
- Support for Amazon EC2 Spot Instances
- Gravatar Support
- Improved Windows process handling

Read more in the Bamboo 3.1 release notes.
See the Bamboo upgrade guide.

Bamboo 3.0

16 February 2011

- Artifact Sharing
- Git Support
- User Interface Overhaul — Redesigned Plan Summary, Job Summary and Build Results. New look and feel.
- Scheduled Repository Polling
- Configuration Changes Captured in Audit Logs

Read more in the Bamboo 3.0 release notes.
See the Bamboo upgrade guide.

Bamboo 2.7

9 Nov 2010

- Build Stages — Map Your Build Process, Parallel Builds, Enhanced Plan Structure
- Simplified Plan Creation
- Concurrent Builds
- Mercurial Support
- Improved Wallboards
- New Plan and Job Configuration Summaries
- Recent History on Plan and Job Summaries
- Other User Interface Enhancements — New Breadcrumb Trail, Build Histories, Improved Build Result Summary Tabs

Read more in the Bamboo 2.7 release notes.

See the Bamboo upgrade guide.

Bamboo 2.6

1 June 2010
- Support for up to 100 Remote Agents
- Revamped Dashboard Pages and Other Usability Enhancements
- Performance and Security Improvements
- Automatically Managed Elastic Instances
- Grails Integration

Read more in the Bamboo 2.6 release notes.

See the Bamboo upgrade guide.

Bamboo 2.5

4 January 2010
- Maven Dependency Management
- Plan Import from a pom.xml
- Additional Bulk Actions
- Streamlined Plan Creation
- Express Setup Wizard

Read more in the Bamboo 2.5 release notes.

See the Bamboo upgrade guide.

Bamboo 2.4

6 October 2009
- Bamboo Gadgets in Jira
- Clover Enhancements
- REST Improvements
- Runtime Log4j Configuration

Read more in the Bamboo 2.4 release notes.

See the Bamboo upgrade guide.

Bamboo 2.3

6 August 2009
- Dependency Blocking Strategies
- New Build Notifications and Queue Reordering
- Bulk Actions
- Multiple Elastic Images
- Elastic Instance Scheduling
- PHPUnit Builder
- Bamboo REST APIs
- Plugins Changes

Read more in the Bamboo 2.3 release notes.

See the Bamboo upgrade guide.

Bamboo 2.2

9 March 2009
- Elastic Bamboo
- Customizable Email Templates
- Build Comment Notification Event
- Hanging Build Detection Event
- Faster Artifact Transfer
- Dependent Builds
- Agent Improvements

Read more in the Bamboo 2.2 release notes.

See the Bamboo upgrade guide.

Bamboo 2.1
5 August 2008
- Link Issues and Builds
- Specify the Issues that are Fixed by a Build
- Track the Builds for your Projects and Versions
- View Issues under Development
- Post Change Detection Plugin Point

Read more in the Bamboo 2.1 release notes.

See the Bamboo upgrade guide.

Bamboo 2.0
14 April 2008
- Distributed builds
- Capability matching
- Memory usage improvements
- Parallel VCS updates and checkouts
- Ability to force a 'clean build'
- Quiet Period functionality supported for Subversion & Perforce
- Bamboo Plugin for Confluence
- Support for Oracle and MS SQL Server databases
- Status Summary screens

Read more in the Bamboo 2.0 release notes.

See the Bamboo upgrade guide.

Bamboo 1.2
09 July 2007
- Permissions (global and plan-based)
- External database support
- Perforce triggering support
- Scheduled backups
- New Bundled NAnt plugin

Read more in the Bamboo 1.2 release notes.

See the Bamboo upgrade guide.

Bamboo 1.1
07 May 2007
- Advanced notifications - rules, triggers, preferences, dynamic recipients
- Build Metadata - pass them to your build, global variables, view them
- File Trigger Inclusions/Exclusions
- More pluggability
- Improved Maven 2 error log parsing
- LDAP and external user management support
- Dashboard loading has been improved

Read more in the Bamboo 1.1 release notes.

See the Bamboo upgrade guide.
We are proud to present Bamboo 6.5 EAP. This release is part of our Early Access Program (EAP) leading up to the official Bamboo 6.5 release. We are making these EAP milestones publicly available so that developers can start assessing the impact of the changes that we are making.

Important

Development releases are snapshots of the ongoing Bamboo development process. For that reason:

- While we try to keep these releases stable, they have not undergone the same degree of testing as a full release.
- Features in development releases may be incomplete, or may change or be removed before the next full release.

Much as you are able to upgrade previous versions of Bamboo to the 6.5 EAP version, and smoothly upgrade from the 6.5 EAP to the final version, once it's released, we don't recommend installing the EAP release on your current production environment. For information about the supported upgrade paths, see Bamboo upgrade guide.

Bamboo Specs run on new repos

Bamboo Specs brings you support for a new set of repositories. Starting from version 6.5, you will be able to use Bamboo Specs Java and YAML with the following repositories:

- Git
- Bitbucket Cloud
- GitHub
- Subversion

For Bamboo Specs to work with repositories other than Bitbucket Server, users will need to set up proper webhooks. The webhooks must send HTTP requests to Bamboo on commits. On each request Bamboo will run "Specs detection" for targeted repository, to see if there are any Specs changes. If so, Bamboo will update necessary plans and deployments.

Bamboo 6.5 EAP ships with Bamboo Specs in version 6.4.1.

To enable webhooks in your repository:

1. In Bamboo, generate a URL used as a destination for your webhook:
   a. In the top navigation bar, click Create > Create Bamboo Specs.
   b. Select your project type.
   c. Select the repository for Bamboo Specs.
   d. Copy the URL that is generated for you as the destination for the webhook.

2. In the repository you want to use for storing Bamboo Specs, use the Bamboo URL to enable the webhook:
   a. Go to your repository settings.
   b. Find webhook-specific configuration.
   c. Paste in the URL Bamboo provided you with.

Bamboo webhook in your repository is now enabled.

New looks

Recently Atlassian has undergone a thorough rebranding which left Bamboo with a new logo. You can enjoy our new look starting from

Bamboo 6.5 EAP Release Notes v6.5

We are proud to present Bamboo 6.5 EAP. This release is part of our Early Access Program (EAP) leading up to the official Bamboo 6.5 release. We are making these EAP milestones publicly available so that developers can start assessing the impact of the changes that we are making.

Important

Development releases are snapshots of the ongoing Bamboo development process. For that reason:

- While we try to keep these releases stable, they have not undergone the same degree of testing as a full release.
- Features in development releases may be incomplete, or may change or be removed before the next full release.

Much as you are able to upgrade previous versions of Bamboo to the 6.5 EAP version, and smoothly upgrade from the 6.5 EAP to the final version, once it's released, we don't recommend installing the EAP release on your current production environment. For information about the supported upgrade paths, see Bamboo upgrade guide.

Bamboo Specs run on new repos

Bamboo Specs brings you support for a new set of repositories. Starting from version 6.5, you will be able to use Bamboo Specs Java and YAML with the following repositories:
For Bamboo Specs to work with repositories other than Bitbucket Server, users will need to set up proper webhooks. The webhooks must send HTTP requests to Bamboo on commits. On each request Bamboo will run “Specs detection” for targeted repository, to see if there are any Specs changes. If so, Bamboo will update necessary plans and deployments.

Bamboo 6.7 EAP ships with Bamboo Specs in version 6.4.1.

To enable webhooks in your repository:

1. In Bamboo, generate a URL used as a destination for your webhook:
   a. In the top navigation bar, click Create > Create Bamboo Specs.
   b. Select your project type.
   c. Select the repository for Bamboo Specs.
   d. Copy the URL that is generated for you as the destination for the webhook.

2. In the repository you want to use for storing Bamboo Specs, use the Bamboo URL to enable the webhook:
   a. Go to your repository settings.
   b. Find webhook-specific configuration.
   c. Paste in the URL Bamboo provided you with.

Bamboo webhook in your repository is now enabled.

New looks

Recently Atlassian has undergone a thorough rebranding which left Bambo with a new logo. You can enjoy our new look starting from version 6.5.

Bamboo 6.5 Release Notes

Bamboo 6.5 Release Notes v6.5

We are proud to present Bamboo 6.5 release. If you're upgrading, read the Bamboo upgrade guide.

Bamboo Specs run on new repos

Bamboo Specs brings you support for a new set of repositories. Starting from version 6.5, you will be able to use Bamboo Specs Java and YAML with the following repositories:

- Bitbucket Cloud
- Git
- GitHub
- Subversion

Webhooks allow your repositories other than Bitbucket Server to communicate with Bamboo. Once you set up a webhook for a repository, it sends the HTTP request to Bamboo with every new commit. This HTTP request, in turn, triggers Bamboo Specs scan repository to see if there are any changes to Specs. If Bamboo detects any changes in a repository, it automatically updates necessary plans and deployments. Learn more about setting up webhooks.

New looks

Recently Atlassian has undergone a thorough rebranding which left Bambo with a new logo. You can enjoy our new look starting from version 6.5.

### Bamboo 6.6 RN

#### Bamboo 6.6 Release Notes v6.6

June 2018

The Atlassian Bamboo team is proud to release **Bamboo 6.6**. If you're upgrading, read the Bamboo **upgrade guide**.

Get the latest version
**Embedded Crowd**

With Bamboo 6.6 we offer you a brand new user directories management mechanism. It significantly enhances remote user resources handling and is free of many known problems with LDAP and Crowd server synchronisation. Moreover, user directories management is now consistent with other Atlassian products such as Jira, Confluence or Bitbucket Server. You're free to define any number of user directories (local, LDAP, external Jira, external Crowd) and configure them to fit your needs.

Bamboo 6.6 drops the feature to write to external Crowd. Since Bamboo 6.6 all external user directories are treated as read only.

**Changelog**

**26 September 2018 - Bamboo 6.6.3**

**Summary**

- Scheduled Elastic Instance startup fails with Hibernate error
- Docker task - "Use the agent’s ~/.dockercfg credentials" registry authentication type is not persisted
- Bamboo branch detection and PR detection queues work as LIFO and not FIFO

3 issues

**16 August 2018 - Bamboo 6.6.2**

**Summary**

- Maven repos do not have Bamboo Specs 6.6.2 files
- XSS when deleting a user alias on user details admin page
- Renaming artifact in YAML break deployment
- [https://ecosystem.atlassian.net/browse/UPM-5903 for Bamboo](https://ecosystem.atlassian.net/browse/UPM-5903 for Bamboo) (on jira.atlassian.com)
- Deployment project item list not updated when plan artifact is added/modified/removed through specs
- Task condition can't prepare data before HTML rendering
- Crowd SSO doesn't work

---

Null data in column "COMMIT_COMMENT_CLOB" of the table DEPLOYMENT_VERSION_COMMIT results into export failure

Security vuln fix request: Open redirect via "cancelUrl" after trying to delete an environment (bypass with unicode characters)

Deployments Dashboard not respecting LIST_POSITION of environments when sorting for display

Showing 10 out of 12 issues

5 July 2018 - Bamboo 6.6.1

Summary

Upgrade can't migrate LDAP/AD that use objectCategory filter
Can't upgrade directly to version 6.6 if Bamboo is connected to Crowd
Ampersand in group name causes incorrect permission display
Concurrent Builds override can be lost when publishing Bamboo Specs
Specs fails to handle Docker job requirement
URL Encode "User management" API calls
Job Requirement is getting deleted when selecting Docker as a requirement.
Viewing Plan Permissions results in NullPointerException if one of the users has no full name

8 issues

26 June 2018 - Bamboo 6.6.0

Summary

Update JRE to latest version 171,172
One of our LDAP user is not able to log into Bamboo. Unable to find the user. The username <em>user-name</em> may be incorrect.
Bamboo does not paginate records over MaxPageSize
Repository password stored in 'Specs' code stored in plain-text
Build succeeds when Bamboo is unable to publish artifact
LDAP users intermittently unable to login
Search available groups functionality - similar to search users.
Stop distributing the user management files at <Bamboo-Install>/webapp/WEB-INF/classes/
Documentation - Integrating Bamboo with LDAP
Documentation: Document what to do when connecting to a remote user repository and the server goes down.

**Bamboo 6.7 Release Notes**

.Bamboo 6.7 Release Notes v6.7

August 2018

Bamboo has grown up a version. Don’t be green and read all about our new 6.7 features here. If you’re upgrading, make sure to swing by the Bamboo upgrade guide.

Get the latest version
**Parsing build warnings**

Bamboo 6.7 introduces a new task which scans build logs and output files for compiler warnings. The warnings are aggregated into a build artifact and the summary of the warnings is displayed in the build result page. You can also decide to fail builds based on the amount and severity of warnings. See Configuring Build warnings parser task.

---

### Build warnings parser configuration

**Task description**
- Parse Java compilation warnings

**Parser**
- Java Compiler (javac)

The parser corresponding to the warnings you want to get.

- **Associate warnings with a repository**
  - Choose whether to associate warnings parsed by this task with a particular repository of this plan.

**Repository**
- Default repository

Repository for which the warnings will be parsed. Default always points to plans default repository.

**Input**
- Parse output logs

Parse output logs produced by preceding tasks.

- **Fail build if too many warnings are found**

**Severity of warnings being counted**
- Medium and high

**Fail build threshold**
- 100

The build will fail if the number of warnings exceeds this number.

---

**New VCS tasks**

There’s a lot going on in the Bamboo Version Control System (VCS) tasks. First of all, to avoid ambiguity, we’ve decided to rename VCS tasks to Repository tasks. Secondly, we’ve added two new VCS tasks: **Commit** and **Push**.

The **Repository Commit** task can commit and push change to a remote repository. The **Repository Push** task, in turn, will only push changes created by other tasks. The repository Commit is designed to to help in simple use cases while Repository Push is intended to be used with more complex workflows.

Finally, we’ve expanded the repository support of Repository tasks from SVN to Git, Mercurial, Bitbucket Server, and Bitbucket Cloud. All repository tasks can now be used in build plans and deployment.
Welcome IPv6

Starting from Bamboo 6.7, we're introducing support for IPv6 environment. We've taken the dual-stack approach (IPv4 + IPv6), so your IPv4 addresses will still work. In most cases there’s nothing you need to do, however there are a few limitations that you need to be aware of. See IPv6 in Bamboo.

Bamboo Docker images

To get Bamboo up and running quickly and to help you isolate Bamboo from other application, we have prepared Bamboo Server and Bamboo Agent Docker images. Both are minimalistic and highly customisable images that allow you to get Bamboo ready for action in no time. You can download both images, Bamboo Server and Bamboo agent base, from the Docker Hub.

Deployment project configuration now in audit log

The audit log just got bigger in Bamboo 6.7. From now on deployment project and environment configuration changes will be logged to the audit log.

We are proud to present Bamboo 6.7 EAP. This release is part of our Early Access Program (EAP) leading up to the official Bamboo 6.7 release. We are making these EAP milestones publicly available so that developers can start assessing the impact of the changes that we are making.

Much as you are able to upgrade previous versions of Bamboo to the 6.7 EAP version, and smoothly upgrade from the 6.7 EAP to the final version, once it's released, we don't recommend installing the EAP release on your current production environment. For information about the supported upgrade paths, see Bamboo upgrade guide.

If you're upgrading, Bamboo 6.7 EAP contains upgrade tasks for changes to the audit log which can impact the upgrade time. It might take you extra 15 minutes for upgrade to Bamboo 6.7 EAP.

- DRAFT - Usage FAQ

### Can multiple plans share a common 3rd-party directory

For example, you might have three repository directories, say, A, B, and C, where A is a common 3rd-party library. A is used across projects.

At this stage, Bamboo doesn't support having multiple checkout directories per build plan. However, you can work around this by setting these three directories up as separate Bamboo build plans - P_A, P_B, and P_C.

To make this work, you will also need to specify as an argument to your build scripts for P_B and P_C the location of A, which will be something like this:

```
../Plan_key_for_A/
```

Using a set up like this, your library module (A) should only be checked out once across the Bamboo instance.

**See also:**
- Triggering a build when another build finishes

### Changing Bamboo database settings

The Bamboo database configuration is persisted in the `<Bamboo-Home>/bamboo.cfg.xml` file. You can change the database settings by editing this file, as detailed in the instructions below:

**Changing the Bamboo database username and password.**
If you want to change the database username and password, edit the following line,

```xml
<property name="hibernate.connection.password">YOUR_PASSWORD</property>
<property name="hibernate.connection.username">YOUR_USERNAME</property>
```

**Changing the Bamboo database URL**

If you want to change the database URL, edit the following line,

```xml
<property name="hibernate.connection.url">DATABASE_URL</property>
```

⚠️ You need to restart the Bamboo application server for the changes to take effect. If you have any elastic agents running, ensure that they are shut down before you restart the Bamboo server. If you do not shut down your elastic instances before restarting, they will continue to run and become orphaned from your Bamboo server.

**Deploying Multiple Atlassian Applications in a Single Tomcat Container**

Deploying multiple Atlassian applications in a single Tomcat container is not supported. We do not test this configuration and upgrading any of the applications (even for point releases) is likely to break it. There are also a number of known issues with this configuration:

- You may not be able to start up all of the applications in the container, due to class conflicts (in 3rd party libraries bundled with our application) that result from the Atlassian applications sharing a single JVM in the Tomcat container.
- You will not be able to determine the startup order of the applications. Hence, you may experience problems such as JIRA starting before Crowd, rather than vice versa.
- Memory problems are also common as one application may allocate all of the memory in the Tomcat JVM to itself, starving the other applications.

We also do not support deploying multiple Atlassian applications to a single Tomcat container for a number of practical reasons. Firstly, you must shut down Tomcat to upgrade any application and secondly, if one application crashes, the other applications running in that Tomcat container will be inaccessible.

Finally, we recommend not deploying any other applications to the same Tomcat container that runs the Atlassian application, especially if these other applications have large memory requirements or require additional libraries in Tomcat's `lib` subdirectory.

**How Bamboo processes task arguments and passes them to OS shell**

- **Parsing arguments**
- **Passing arguments to shell**
- **FAQ**
  - I want to pass double quotes with my argument to Unix shell.
  - My Maven Task doesn't work when I specify multiple targets in argument field

**Parsing arguments**

When executing different Tasks, Bamboo attempts to tokenize value entered in Arguments field. The general rules are:

- white characters are argument separators,
- single and double quotes are used to preserve white characters in arguments.

This particular string

```shell
clean install -DpartiallyQuotedArgument1="Partially Quoted Argument"
'Fully Quoted Argument'
```

would be tokenized as

```shell
clean install
-DpartiallyQuotedArgument1="Partially Quoted Argument"
'Fully Quoted Argument'
```

Each line here represents a single argument that will be passed to shell.

**Passing arguments to shell**
Bamboo generally doesn't modify tokenized arguments before passing them to shell with one exception:

- on non-Windows OS arguments that are fully enclosed in single or double quotes will be stripped from those quotes.

This particular string

```
clean install -DpartiallyQuotedArgument1="Partially Quoted Argument"
'Fully Quoted Argument'
```

would be passed to Windows shell as

```
clean
install
-DpartiallyQuotedArgument1="Partially Quoted Argument"
'Fully Quoted Argument'
```

but to Unix shell as

```
clean
install
-DpartiallyQuotedArgument1="Partially Quoted Argument"
Fully Quoted Argument
```

**FAQ**

*I want to pass double quotes with my argument to Unix shell.*

Try this

```
"Only external quotes will be stripped and double quotes will be preserved when passing this to Unix shell"
```

*My Maven Task doesn't work when I specify multiple targets in argument field*

Make sure you haven't quoted the whole contents of Arguments field:

```
"clean install"
```

You should simply delete quotes

```
clean install
```

**Securing your repository connection**

**About this page**

This page shows how to secure your bamboo server to source repository connection.

**Subversion**

**svn+ssh**

In your build plan you must specify the absolute path to the repository when using svn+ssh, for example

```
svn+ssh://<svnhost>/absolute/path/to/repository/root/your/module
```
Using a key pair

They key pair is shared between your bamboo agent box (the bamboo server box in case of local agents) and the repository server box. Your repository configuration allows you to specify the location of a private key file that must be stored on the agent box.

The key pair has to be in PKCS12/OpenSSH format and the private key must be passphrase protected, otherwise a runtime exception is thrown by JDK security engine while opening the user key.

Linux and related

1. On the repository box generate the keypair

   ```
   ssh-keygen -t rsa
   ```

2. add public key to ~/.ssh/authorized_keys

   ```
   cat id_rsa.pub >> ~/.ssh/authorized_keys
   ```

3. copy the private key to all the agent boxes into a directory that is common to all agents (remote and local) e.g.

   ```
   /var/keys/ssh/id_rsa
   ```

For windows agents

Store the private key file in the same location on the drive that the agent is started from. For example you start your agent with

```d:\bamboo-agent > java -jar
atlassian-bamboo-agent-installer-xxx.jar ....
```

Then the key file must be in

```d:\var\keys\ssh\id_rsa```

Windows

Private key should always be in OpenSSH format. On windows usually "putty" (plink) program is used that uses keys in its proprietary format (PPK - putty private key), this format is not supported by bamboo. The PuttyGen program may be used on Windows to convert key in PPK format to OpenSSH.

How to add the public key to the windows version of ~/.ssh/authorized_keys <<<< comment needed

Trouble shooting

You can test the svn+ssh connection from the command line. First you need to tell the svn command line client which key file to use:

```$ export SVN_SSH="ssh -i /absolute/path/to/private/key"
```

Then you can test the connection with

```$ svn list svn+ssh://<svn-server>/Absolute/Path/To/Repository/[Module]```

Changing the remote agent heartbeat interval

Remote agents periodically send a "heartbeat" signal to the Bamboo server. This is vital for tracking whether your remote agents are online or offline. The remote heartbeat is asynchronous, which means that if a remote agent goes offline and comes back online again it will reconnect instead of being shut down (as long as the same server is available).

However, you may wish to adjust the time parameters for the remote agent heartbeat, particularly if you have a lot of network activity already.

There are three configurable parameters on the bamboo server for the remote agent heartbeat:

```bamboo.agent.heartbeatInterval=60```
The frequency of the heartbeat signal from remote agents. The value is in seconds

**bamboo.agent.heartbeatInterval=60**

How often Bamboo checks for agents that have exceeded the heartbeat timeout specified in `bamboo.agent.heartbeatTimeoutSeconds`. The value is in seconds.

**bamboo.agent.heartbeatTimeoutSeconds=600**

How long the Bamboo server will wait before it times out an agent that it hasn't received a heartbeat signal from. A remote agent that has been timed out will be marked as 'Offline'. Any builds being run by agents which have timed out will be abandoned. The value is in seconds.

**bamboo.agent.heartbeatCheckInterval=30**

How often the Bamboo server will wait before it times out an agent that it hasn't received a heartbeat signal from. A remote agent that has been timed out will be marked as 'Offline'. Any builds being run by agents which have timed out will be abandoned.

See Configuring Bamboo on startup for instructions on how to change a Bamboo system property.

### Changing the remote agent heartbeat interval v5.14

Remote agents periodically send a "heartbeat" signal to the Bamboo server. This is vital for tracking whether your remote agents are online or offline. The remote heartbeat is asynchronous, which means that if a remote agent goes offline and comes back online again it will reconnect instead of being shut down (as long as the same server is available).

However, you may wish to adjust the time parameters for the remote agent heartbeat, particularly if you have a lot of network activity already.

There are three configurable parameters on the bamboo server for the remote agent heartbeat:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bamboo.agent.heartbeatInterval=60</code></td>
<td>The frequency of the heartbeat signal from remote agents. The value is in seconds.</td>
</tr>
<tr>
<td><code>bamboo.agent.heartbeatTimeoutSeconds=600</code></td>
<td>How long the Bamboo server will wait before it times out an agent that it hasn't received a heartbeat signal from. A remote agent that has been timed out will be marked as 'Offline'. Any builds being run by agents which have timed out will be abandoned. The value is in seconds.</td>
</tr>
<tr>
<td><code>bamboo.agent.heartbeatCheckInterval=30</code></td>
<td>How often Bamboo checks for agents that have exceeded the heartbeat timeout specified in <code>bamboo.agent.heartbeatTimeoutSeconds</code>. The value is in seconds.</td>
</tr>
</tbody>
</table>

See Configuring Bamboo on startup for instructions on how to change a Bamboo system property.

### Changing the remote agent heartbeat interval v6.1

Remote agents periodically send a "heartbeat" signal to the Bamboo server. This is vital for tracking whether your remote agents are online or offline. The remote heartbeat is asynchronous, which means that if a remote agent goes offline and comes back online again it will reconnect instead of being shut down (as long as the same server is available).

However, you may wish to adjust the time parameters for the remote agent heartbeat, particularly if you have a lot of network activity already.

There are three configurable parameters on the bamboo server for the remote agent heartbeat:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bamboo.agent.heartbeatInterval=60</code></td>
<td>The frequency of the heartbeat signal from remote agents. The value is in seconds.</td>
</tr>
<tr>
<td><code>bamboo.agent.heartbeatTimeoutSeconds=600</code></td>
<td>How long the Bamboo server will wait before it times out an agent that it hasn't received a heartbeat signal from. A remote agent that has been timed out will be marked as 'Offline'. Any builds being run by agents which have timed out will be abandoned. The value is in seconds.</td>
</tr>
<tr>
<td><code>bamboo.agent.heartbeatCheckInterval=30</code></td>
<td>How often Bamboo checks for agents that have exceeded the heartbeat timeout specified in <code>bamboo.agent.heartbeatTimeoutSeconds</code>. The value is in seconds.</td>
</tr>
</tbody>
</table>

See Configuring Bamboo on startup for instructions on how to change a Bamboo system property.

### Cloning a Bamboo instance

You can clone an existing Bamboo instance by getting a new Bamboo instance in the same version and using the setup of the existing one.

You may want to transfer a snapshot of your current production Bamboo instance to a test server as permitted in the license agreement.

Cloning Bamboo can be a step in preparation for migrating to another database or for upgrading.
License

Development licenses are available for any Commercial or Academic license. Create one or contact us for help.

Cloning a Bamboo instance to a new server

To clone a Bamboo instance to a new server:

1. Export/Backup your original Bamboo instance.
2. Install the same version of Bamboo on the new server.
3. On the new server, in the new <bamboo-install> directory, go to webapp/WEB-INF/classes/ and open the bamboo-init.properties file. In the bamboo-init.properties file, set the new <bamboo-home> path.
4. Start the new Bamboo instance and import the existing export/backup data prepared in Step 1.

Alternative cloning scenario

If your current instance has grown too large and export/import does not work, you can still clone your instance by using an alternative backup and restore strategy.

The approach is to clone the <bamboo-home> content and make it available to the new Bamboo instance:

1. Stop the original Bamboo instance.
2. Create a backup:
   - Compress the original <bamboo-home> directory into a .zip file. The embedded database is included in the directory.
   - Compress the original <bamboo-home> directory into a .zip file.
   - Create a database backup with the native tools.

You can reduce the size of a compressed <bamboo-production-home> file by deleting the xml-data/build-dir directory that contains working copies of the checked-out sources.

For more information about migrating databases, see Moving your Bamboo data to a different database.
3. Restart the original Bamboo instance.
4. Install the same version of Bamboo on the new server.

If you are cloning a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same <bamboo-home> installation path as the original Bamboo instance.
5. Transfer the compressed original <bamboo-home> directory to the new server where you installed the new Bamboo instance.
6. Replace the content of the new `<bamboo-home>` directory with the unzipped `<home-directory>` content.
7. On the new server, in the new `<bamboo-install>` directory, go to `webapp/WEB-INF/classes/` and open the `bamboo-init.properties` file. In the `bamboo-init.properties` file, set the new `<bamboo-home>` path.

   If you are cloning a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same `<bamboo-home>` path as the original Bamboo instance.

8. (External DB only) Create a new database for the cloned instance and import the external database backup.
9. In the new `<bamboo-home>` directory, open:
   - `bamboo.cfg.xml`
   - `xml-data/configuration/administration.xml`

   and change the server names/IP addresses according to the new location.
10. (External DB only) Go to the new `<bamboo-home>` directory, open the `bamboo.cfg.xml` file, and enter the new database connection details and credentials.
11. Start the new Bamboo instance.

Next steps

- (Optional) You can upgrade the new Bamboo instance.
- If the new server has different locations for:
  - JDKs
  - Ant
  - Maven
  - Perforce
  - Msbuild tools

  adjust the settings in the server capabilities settings to match the locations on the new server.

Cloning a Bamboo instance v5.14

You can clone an existing Bamboo instance by getting a new Bamboo instance in the same version and using the setup of the existing one.

You may want to transfer a snapshot of your current production Bamboo instance to a test server as permitted in the license agreement.

Cloning Bamboo can be a step in preparation for migrating to another database or for upgrading.

If you are using Jira or Crowd for user management, the URL of the Bamboo server may change when you clone the Bamboo instance, in which case you will need to edit that setting for the Bamboo application in Jira/CROWD to match the new URL.

License

Development licenses are available for any Commercial or Academic license. Create one or contact us for help.

**Cloning a Bamboo instance to a new server**

To clone a Bamboo instance to a new server:

1. Export/Backup your original Bamboo instance.
2. Install the same version of Bamboo on the new server.

   If you are cloning a Bamboo instance on the same server, make sure that the original Bamboo instance doesn't have the same `<bamboo-install>` installation path as the new Bamboo instance.

3. On the new server, in the new `<bamboo-install>` directory, go to `webapp/WEB-INF/classes/` and open the `bamboo-init.properties` file. In the `bamboo-init.properties` file, set the new `<bamboo-home>` path.

   If you are cloning a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same `<bamboo-home>` path as the original Bamboo instance.

4. Start the new Bamboo instance and import the existing export/backup data prepared in Step 1.
Alternative cloning scenario

If your current instance has grown too large and export/import does not work, you can still clone your instance by using an alternative backup and restore strategy.

The approach is to clone the `<bamboo-home>` content and make it available to the new Bamboo instance:

1. Stop the original Bamboo instance.
2. Create a backup:

<table>
<thead>
<tr>
<th>embedded DB</th>
<th>external DB</th>
</tr>
</thead>
</table>
   | Compress the original `<bamboo-home>` directory into a .zip file. The embedded database is included in the directory. | • Compress the original `<bamboo-home>` directory into a .zip file.  
   |                      | • Create a database backup with the native tools. |

You can reduce the size of a compressed `<bamboo-production-home>` file by deleting the xml-data/build-dir directory that contains working copies of the checked-out sources.

For more information about migrating databases, see Moving your Bamboo data to a different database.

3. Restart the original Bamboo instance.

  • JDKs
  • Ant
  • Maven
  • Perforce
  • Msbuild tools
  adjust the settings in the server capabilities settings to match the locations on the new server.

Cloning a Bamboo instance v6.0

You can clone an existing Bamboo instance by getting a new Bamboo instance in the same version and using the setup of the existing one.

You may want to transfer a snapshot of your current production Bamboo instance to a test server as permitted in the license agreement.

Cloning Bamboo can be a step in preparation for migrating to another database or for upgrading.
Cloning a Bamboo instance to a new server

To clone a Bamboo instance to a new server:

1. Export/Backup your original Bamboo instance.
2. Install the same version of Bamboo on the new server.
3. On the new server, in the new `<bamboo-install>` directory, go to `webapp/WEB-INF/classes/` and open the `bamboo-init.properties` file. In the `bamboo-init.properties` file, set the new `<bamboo-home>` path.
4. Start the new Bamboo instance and import the existing export/backup data prepared in Step 1.

Alternative cloning scenario

If your current instance has grown too large and export/import does not work, you can still clone your instance by using an alternative backup and restore strategy. The approach is to clone the `<bamboo-home> content and make it available to the new Bamboo instance:

1. Stop the original Bamboo instance.
2. Create a backup:

<table>
<thead>
<tr>
<th>embedded DB</th>
<th>external DB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compress the original <code>&lt;bamboo-home&gt;</code> directory into a .zip file. The embedded database is included in the directory.</td>
<td>• Compress the original <code>&lt;bamboo-home&gt;</code> directory into a .zip file. • Create a database backup with the native tools.</td>
</tr>
</tbody>
</table>

You can reduce the size of a compressed `<bamboo-production-home>` file by deleting the `xml-data/build-dir` directory that contains working copies of the checked-out sources.

For more information about migrating databases, see Moving your Bamboo data to a different database.

3. Restart the original Bamboo instance.
4. Install the same version of Bamboo on the new server.
5. Transfer the compressed original `<bamboo-home>` directory to the new server where you installed the new Bamboo instance.
6. Replace the content of the new `<bamboo-home>` directory with the unzipped `<home-directory>` content.
7. On the new server, in the new `<bamboo-install>` directory, go to `webapp/WEB-INF/classes/` and open the `bamboo-init.properties` file. In the `bamboo-init.properties` file, set the new `<bamboo-home>` path.

If you are cloning a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same `<bamboo-home>` path as the original Bamboo instance.

8. (External DB only) Create a new database for the cloned instance and import the external database backup.

9. In the new `<bamboo-home>` directory, open:
   - `bamboo.cfg.xml`
   - `xml-data/configuration/administration.xml`

   and change the server names/IP addresses according to the new location.

10. (External DB only) Go to the new `<bamboo-home>` directory, open the `bamboo.cfg.xml` file, and enter the new database connection details and credentials.

11. Start the new Bamboo instance.

Next steps

- (Optional) You can upgrade the new Bamboo instance.
- If the new server has different locations for:
  - JREs
  - Ant
  - Maven
  - Perforce
  - Msbuild tools

  adjust the settings in the `server capabilities settings` to match the locations on the new server.

Cloning a Bamboo instance v6.4

You can clone an existing Bamboo instance by getting a new Bamboo instance in the same version and using the setup of the existing one.

You may want to transfer a snapshot of your current production Bamboo instance to a test server as permitted in the license agreement.

Cloning Bamboo can be a step in preparation for migrating to another database or for upgrading.

- If you are using Jira or Crowd for user management, the URL of the Bamboo server may change when you clone the Bamboo instance, in which case you will need to edit that setting for the Bamboo application in Jira/CROWD to match the new URL.
- When cloning your Bamboo instance using the export/import process, you must re-install all of your add-ons manually.

License

Development licenses are available for any Commercial or Academic license. Create one or contact us for help.

Cloning a Bamboo instance to a new server

To clone a Bamboo instance to a new server:

1. Export/Backup your original Bamboo instance.
2. Install the same version of Bamboo on the new server.

   If you are cloning a Bamboo instance on the same server, make sure that the original Bamboo instance doesn't have the same `<bamboo-install>` installation path as the new Bamboo instance.

3. On the new server, in the new `<bamboo-install>` directory, go to `webapp/WEB-INF/classes/` and open the `bamboo-init.properties` file. In the `bamboo-init.properties` file, set the new `<bamboo-home>` path.

   If you are cloning a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same `<bamboo-home>` path as the original Bamboo instance.

4. Start the new Bamboo instance and import the existing export/backup data prepared in Step 1.
**Alternative cloning scenario**

If your current instance has grown too large and export/import does not work, you can still clone your instance by using an alternative backup and restore strategy.

The approach is to clone the `<bamboo-home>` content and make it available to the new Bamboo instance:

1. Stop the original Bamboo instance.
2. Create a backup:
   - **embedded DB**
     - Compress the original `<bamboo-home>` directory into a .zip file. The embedded database is included in the directory.
   - **external DB**
     - Compress the original `<bamboo-home>` directory into a .zip file.
     - Create a database backup with the native tools.

You can reduce the size of a compressed `<bamboo-production-home>` file by deleting the xml-data/build-dir directory that contains working copies of the checked-out sources.

For more information about migrating databases, see [Moving your Bamboo data to a different database](#).

3. Restart the original Bamboo instance.
4. **Install the same version** of Bamboo on the new server.

   If you are cloning a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same `<bamboo-install>` installation path as the original Bamboo instance.

5. Transfer the compressed original `<bamboo-home>` directory to the new server where you installed the new Bamboo instance.
6. Replace the content of the new `<bamboo-home>` directory with the unzipped `<home-directory>` content.
7. On the new server, in the new `<bamboo-install>` directory, go to `webapp/WEB-INF/classes/` and open the `bamboo-init.properties` file. In the `bamboo-init.properties` file, set the new `<bamboo-home>` path.

   If you are cloning a Bamboo instance on the same server, make sure that the new Bamboo instance doesn't have the same `<bamboo-home>` path as the original Bamboo instance.

8. (External DB only) Create a new database for the cloned instance and import the external database backup.
9. In the new `<bamboo-home>` directory, open:
   - `bamboo.cfg.xml`
   - `xml-data/configuration/administration.xml`
   - and change the server names/IP addresses according to the new location.
10. (External DB only) Go to the new `<bamboo-home>` directory, open the `bamboo.cfg.xml` file, and enter the new database connection details and credentials.

    Before starting Bamboo, depending on your motivation for cloning, you may also want to ensure any customizations that were made in the previous Bamboo instance’s installation directory are also copied to the clone. Examples of customizations include proxy settings, additional JVM arguments and JVM memory allocation tweaks. These customizations most commonly exist in:

    - `<bamboo-install>/bin/setenv.sh`
    - `<bamboo-install>/conf/server.xml`

11. Start the new Bamboo instance.

**Next steps**

- (Optional) You can upgrade the new Bamboo instance.
- If the new server has different locations for:
  - JDKs
  - Ant
  - Maven
  - Perforce
  - Msbuild tools
  
  adjust the settings in the server capabilities settings to match the locations on the new server.
How do I connect Bamboo to an unsupported database

We strongly recommend that you use Bamboo with one of the databases that we support (see Supported platforms for details). However, if you wish to connect Bamboo to an unsupported database, you can do so using the instructions below.

First, choose one of the following methods by which you will connect to your database:

- Connecting using JDBC
- Connecting using a datasource.

Then follow the instructions for that method. Note that using JDBC is generally simpler, and is therefore the recommended method.

On this page:
- Connecting using JDBC
- Connecting using a datasource

- Troubleshooting Databases

Connecting using JDBC

To connect Bamboo to an unsupported database, using JDBC:

1. Put the appropriate JDBC driver jar file into your application server's classpath by copying the jar file into the webapp/WEB-INF/lib directory.
2. Set the following system property before starting your upgraded Bamboo server to enable "Unsupported Database" as a selectable option in the Setup Wizard:
   -Dbamboo.enable.unsupported.db=true
3. At Step 2 of the Bamboo Setup Wizard, choose External Database > Unsupported Database.
4. In the 'Select Database Connection' screen, choose Direct JDBC connection.
5. In the 'Setup JDBC Connection' screen, make the following settings:

   - **Driver Class Name**: The classname of your JDBC driver (consult your JDBC driver documentation for details).
   - **Database URL**: The URL where Bamboo will access your database (consult your JDBC driver documentation for details).
   - **UserName**: The username that Bamboo will use to access your database.
   - **Password**: The password (if required) that Bamboo will use to access your database.
   - **Hibernate Dialect**: The Hibernate dialect for your particular database. Using these databases is not recommended as there is no guarantee that they will operate correctly with Bamboo. Please consider using a supported database instead.
   - **Overwrite existing data**: Select if you wish Bamboo to overwrite any tables that already exist in the database.

6. Go to Step 3 of the Setup Wizard.

Connecting using a datasource

To connect Bamboo to an unsupported database, using a datasource:

1. Configure a datasource in your application server (consult your application server documentation for details). For the syntax of the JDBC URL to use, please see your JDBC driver documentation.
2. Set the following system property before starting your upgraded Bamboo server to enable "Unsupported Database" as a selectable option in the Setup Wizard:
   -Dbamboo.enable.unsupported.db=true
3. At Step 2 of the Bamboo Setup Wizard, choose External Database > Unsupported Database from the list.
4. In the 'Select Database Connection' screen, select Connect via a datasource (configured in the application server).
5. The 'Setup Datasource Connection' screen is displayed. In the JNDI name field, type the JNDI name of your datasource, as configured in your application server.
   
   ![If java:comp/env/jdbc/DataSourceName doesn't work, try jdbc/DataSourceName (and vice versa).]

6. Select Overwrite existing data if you wish Bamboo to overwrite any tables that already exist in the database.
7. Go to Step 3 of the Setup Wizard.

How do I connect Bamboo to an unsupported database v5.14

We strongly recommend that you use Bamboo with one of the databases that we support (see Supported platforms for details). However, if you wish to connect Bamboo to an unsupported database, you can do so using the instructions below.
First, choose one of the following methods by which you will connect to your database:

### Connecting using JDBC

To connect Bamboo to an unsupported database, using JDBC:

1. Put the appropriate JDBC driver jar file into your application server's classpath by copying the jar file into the `webapp/WEB-INF/lib` directory.
2. Set the following system property before starting your upgraded Bamboo server to enable "Unsupported Database" as a selectable option in the Setup Wizard:
   ```
   -Dbamboo.enable.unsupported.db=true
   ```
3. At Step 2 of the Bamboo Setup Wizard, choose External Database > Unsupported Database.
4. In the 'Select Database Connection' screen, choose **Direct JDBC connection**.
5. In the 'Setup JDBC Connection' screen, make the following settings:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Driver Class Name</td>
<td>The classname of your JDBC driver (consult your JDBC driver documentation for details).</td>
</tr>
<tr>
<td>Database URL</td>
<td>The URL where Bamboo will access your database (consult your JDBC driver documentation for details).</td>
</tr>
<tr>
<td>UserName</td>
<td>The username that Bamboo will use to access your database.</td>
</tr>
<tr>
<td>Password</td>
<td>The password (if required) that Bamboo will use to access your database.</td>
</tr>
<tr>
<td>Hibernate Dialect</td>
<td>The Hibernate dialect for your particular database. Using these databases is not recommended as there is no guarantee that they will operate correctly with Bamboo. Please consider using a supported database instead.</td>
</tr>
</tbody>
</table>

6. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
7. Go to Step 3 of the Setup Wizard.

### Connecting using a datasource

To connect Bamboo to an unsupported database, using a datasource:

1. Configure a datasource in your application server (consult your application server documentation for details). For the syntax of the JDBC URL to use, please see your JDBC driver documentation.
2. Set the following system property before starting your upgraded Bamboo server to enable "Unsupported Database" as a selectable option in the Setup Wizard:
   ```
   -Dbamboo.enable.unsupported.db=true
   ```
3. At Step 2 of the Bamboo Setup Wizard, choose External Database > Unsupported Database.
4. In the 'Select Database Connection' screen, choose **Connect via a datasource (configured in the application server)**.
5. The 'Setup Datasource Connection' screen is displayed. In the **JNDI name** field, type the JNDI name of your datasource, as configured in your application server.

   ```
   java:comp/env/jdbc/DataSourceName
   ```

   ```
   jdbc/DataSourceName
   ```

6. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
7. Go to Step 3 of the Setup Wizard.

### How do I connect Bamboo to an unsupported database v6.1

We strongly recommend that you use Bamboo with one of the databases that we support (see Supported platforms for details). However, if you wish to connect Bamboo to an unsupported database, you can do so using the instructions below.

First, choose one of the following methods by which you will connect to your database:

- Connecting using JDBC
Then follow the instructions for that method. Note that using JDBC is generally simpler, and is therefore the recommended method.

**On this page:**

- Connecting using JDBC
- Connecting using a datasource

## Connecting using JDBC

To connect Bamboo to an unsupported database, using JDBC:

1. Put the appropriate JDBC driver jar file into your application server's classpath by copying the jar file into the webapp WEB-INF/lib directory.
2. Set the following system property before starting your upgraded Bamboo server to enable "Unsupported Database" as a selectable option in the Setup Wizard:
   ```
   -Dbamboo.enable.unsupported.db=true
   ```
3. At Step 2 of the Bamboo Setup Wizard, choose External Database > Unsupported Database.
4. In the 'Select Database Connection' screen, choose Direct JDBC connection.
5. In the 'Setup JDBC Connection' screen, make the following settings:

   - **Driver Class Name**: The classname of your JDBC driver (consult your JDBC driver documentation for details).
   - **Database URL**: The URL where Bamboo will access your database (consult your JDBC driver documentation for details).
   - **UserName**: The username that Bamboo will use to access your database.
   - **Password**: The password (if required) that Bamboo will use to access your database.
   - **Hibernate Dialect**: The Hibernate dialect for your particular database. Using these databases is not recommended as there is no guarantee that they will operate correctly with Bamboo. Please consider using a supported database instead.
6. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
7. Go to Step 3 of the Setup Wizard.

### Connecting using a datasource

To connect Bamboo to an unsupported database, using a datasource:

1. Configure a datasource in your application server (consult your application server documentation for details). For the syntax of the JDBC URL to use, please see your JDBC driver documentation.
2. Set the following system property before starting your upgraded Bamboo server to enable "Unsupported Database" as a selectable option in the Setup Wizard:
   ```
   -Dbamboo.enable.unsupported.db=true
   ```
3. At Step 2 of the Bamboo Setup Wizard, choose External Database > Unsupported Database from the list.
4. In the 'Select Database Connection' screen, select **Connect via a datasource (configured in the application server)**.
5. The 'Setup Datasource Connection' screen is displayed. In the JNDI name field, type the JNDI name of your datasource, as configured in your application server.
6. If java:comp/env/jdbc/DataSourceName doesn't work, try jdbc/DataSourceName (and vice versa).
7. Select **Overwrite existing data** if you wish Bamboo to overwrite any tables that already exist in the database.
8. Go to Step 3 of the Setup Wizard.

## How do I shut down my elastic instances if I have restarted my Bamboo server

If you restart your Bamboo server without shutting down your elastic instances first, your elastic instances will continue to run. Your elastic instances will also be orphaned from your Bamboo server, and you will not be able to shut them down via Bamboo after your Bamboo server has restarted. You will need to terminate them via the Amazon Web Services (AWS) Console.

To shut down an elastic instance via the AWS Console:

1. Log in to the AWS Console. The 'Amazon EC2' tab of the console should display.
2. Click the **Instances** link under the 'Images & Instances' section of the left navigation column. Your EC2 instances should be displayed.
3. Check the checkbox next to the instances that need to be terminated in the 'My Instances' panel. In most cases, it should be all instances unless you are running Elastic Bamboo on multiple Bamboo servers.
4. The buttons at the top of the 'My Instances' panel should become enabled. Click **Terminate** to terminate your instances.

**Screenshot: Shutting down an elastic instance via the AWS Console**

How do I stop the Bamboo server from automatically configuring my remote agent's capabilities

The Bamboo server automatically detects and populates the capabilities that a remote agent should be configured with upon agent start up. If you have modified the agent capabilities, they will be reset by the server's automatic capability detection when the agent is next restarted.

You can override this by adding the following flag, "--DISABLE_AGENT_AUTO_CAPABILITY_DETECTION=true", to the Bamboo server. Read [Starting Bamboo](#) for information on how to do this.

**JUnit parsing in Bamboo**

Bamboo can parse any test output that conforms to standard JUnit XML format. The implementation of this is pretty simple — Bamboo looks for specific tags in the JUnit XML output.

A failed JUnit XML report, that is successfully parsed by Bamboo.

```xml
<testsuite errors="0" tests="3" time="0.391" failures="1"
name="com.atlassian.bamboo.repository.perforce.PerforceSyncCommandTest">
    <properties>
        <property value="Java(TM) 2 Runtime Environment, Standard Edition" name="java.runtime.name"/>
        <property value="UnicodeBig" name="sun.io.unicode.encoding"/>
    </properties>
    <testcase time="0.001" name="testGeneratesCorrectP4CommandLine"/>
    <testcase time="0" name="testGettersReturnExpectedStuff"/>
    <testcase time="0.164" name="testUsingPerforceWhenNoFilesHaveChanged">
        <failure type="junit.framework.AssertionFailedError" message="Should not have any errors. [Perforce client error: Connect to server failed; ]">
            junit.framework.AssertionFailedError: Should not have any errors. [Perforce client error: Connect to server failed; check $P4PORT, TCP connect to keg failed., keg: host unknown.] expected:&lt;0&gt; but was:&lt;4&gt; at junit.framework.Assert.fail (Assert.java:47)
        </failure>
    </testcase>
</testsuite>

Known issues with CVS in Bamboo

Bamboo uses CVS `rlog` command - this lets you perform a CVS update on your local working directory without checking out your project.

**CVS Error logging in Bamboo**
Currently, if the server throws an error during a CVS build in Bamboo versions 2.0.x, the application will hang with no indication of any checkout/update problems. There is an open Jira issue tracking this problem.

In order to further debug any CVS issues, you will need to turn up the CVS logging by passing in the `-DcvsClientLog=system` argument to Bamboo.

1) **Incompatibility with CVS servers 1.11.1 and below**
Support for the `rlog` command 1.11.1p and performing a CVS `rlog` command returns the following error:

```
-cvs [rlog aborted]: server does not support rlog
```

2) **Incompatibility with CVS server version 1.11.x when using "." to denote the root module to be checked out.**
The CVS `rlog` command fails if you are using CVS version 1.11.x, with the following error.

```
INFO   | jvm 1    | 2008/05/15 14:19:10 | E cvs: recurse.c:642: do_recursion: Assertion `strstr (repository, "/./") == ((void *)0)’ failed.
INFO   | jvm 1    | 2008/05/15 14:19:10 | error
```

Please upgrade your CVS version to 1.12.x to get around this issue.

3) **CVS Checkout format**
Due to prior issues, Bamboo will checkout all files (including text files) from the CVS server as binary, however post Bamboo 2.1.2 this behavior can be changed via a system parameter. To do this restart Bamboo with the following parameter (if you have any elastic agents running, ensure that they are shut down before you restart the Bamboo server. If you do not shut down your elastic instances before restarting, they will continue to run and become orphaned from your Bamboo server).

```
-DCVS_CHECKOUT_BINARY_FORMAT=false
```

Post 2.1.5 this has been replaced with a more flexible option

```
-DCVS_CHECKOUT_FORMAT=BINARY
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Command Options</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY (Default)</td>
<td>-b</td>
<td>forces all files to be checked out in binary and won't convert any line endings</td>
</tr>
<tr>
<td>TEXT</td>
<td>-kv</td>
<td>forces all files to be checked out as text and converts all line endings (even Binary files)</td>
</tr>
</tbody>
</table>
Monitoring and Profiling Bamboo

This page helps you to set up profiling for bamboo. Profiling information can be useful to monitor bamboo’s performance, memory consumption and the server’s CPU load.

On this page
- Profiling with JMX
  - Enabling the profiler
  - Monitoring and Controlling the Profiler with JConsole
- Profiling with Yourkit
  - Installing Yourkit
  - Enabling the profiler

Profiling with JMX

Enabling the profiler

JMX is Sun’s native java platform monitor. JConsole can be used to visualize the profiling data.

To enable JMX add -Dcom.sun.management.jmxremote (or -Dcom.sun.management.jmxremote.port=<portNum> for remote monitoring) as a command line argument when starting bamboo.

For Unix: add the parameter to the RUN_CMD line in bamboo.sh
For Windows: add the parameter to the \conf\wrapper.conf file as wrapper.java.additional.4=-D....

Restart Bamboo.

Does not work when bamboo is run as a windows service
At the moment profiling via JMX only works when bamboo is run as a console application on windows.
Running bamboo as a windows service with profiling is currently not supported.

Monitoring and Controlling the Profiler with JConsole

Please refer to Sun’s documentation

Profiling with Yourkit

Installing Yourkit

Yourkit is an alternative (commercial) java profiler. Follow the installation instructions for your platform. You do not need a license if you just run the profiling agent with bamboo.

Enabling the profiler

Add -agentlib:yjpagent=onexit=snapshot to the command line in bamboo.sh or as an additional parameter to wrapper.conf

Then follow the instructions on enabling the profiler manually for your platform.

Restart Bamboo.

Monitor Memory usage and Garbage Collection in Bamboo

A simple way to do this is to turn on garbage collection and heap dump on out of memory.

Parameters

Please add the following parameters to Bamboo
Documentation for Bamboo 6.7

```
-XX:+PrintGCDetails -XX:+PrintGCTimeStamps -verbose:gc
-Xloggc:/path/to/gc.log
```

**Note:** Remember to substitute `/path/to/gc.log` with a meaningful file path on your server.

**GC log file location**

The garbage collection traces and the heap dumps are in `<bamboo-install>/gc.log`.

**Additional Note**

The `-XX:+PrintGCTimeStamps` flag, prints when GCs happen relative to the start of the application.

**Some helpful links:**

- [http://www.oracle.com/technetwork/articles/javase/gcportal-136937.html](http://www.oracle.com/technetwork/articles/javase/gcportal-136937.html)

**Moving Bamboo-Home of an agent**

To move an agent's Bamboo-Home -

1. Move the Bamboo-Home of the agent, to the intended location.
2. Edit the `<Bamboo-Agent-Home>/bamboo-agent.cfg.xml` file, find the following line -

   ```
   ``

3. Point the working directory and the artifact directory to the new Bamboo-Home.
4. Start your Agent with `-Dbamboo.home=your_new_agent_home` and point to your new Bamboo-Agent-Home.

**Performing a thread dump**

If Bamboo stops responding, or is performing poorly, you should create a thread dump to help Atlassian determine the cause of the problem.

This will show the state of each thread in the JVM, including a stack trace and information about what locks that thread is holding and waiting for.

**Linux (and Solaris and other Unixes) Users**

Find the process id of the JVM and issue the command:

```bash
ps
```

Use the `ps` command to get list of all processes.

```bash
kill -3 <pid>
```

**Note:** This will not kill your server (so long as you included the "-3" option, no space in between). The thread dump will be printed to Bamboo's standard output.

**Note:** This will not kill your server (so long as you included the "-3" option, no space in between). The thread dump will be printed to Bamboo's standard output.

Please note that some application servers (like tomcat) redirect stdout (to catalina.out for instance).

**Jstack (any Platform with an JAVA JDK)**

Sun JDK 1.5 and above ship with native tool called `jstack` to perform thread dump. To use the tool find the Process ID and execute the command:
If you run your Atlassian product via wrapper (as a service) on Windows, you may encounter this error, 'Not enough storage is available to process this command'. See the suggestions in this KB article for workarounds.

**Java VisualVM (any Platform with an JAVA JDK)**

Oracle JDK has a native tool `jvisualvm` to perform thread dumps (and much more). To use the tool execute the command:

```
jvisualvm
```

Find Bamboo process `{{com.atlassian.bamboo.server.Server}}` and execute "Thread Dump" option available from a context menu.

**Thread Dump Tools**

- Samurai
- Thread Dump Analyzer TDA

**Performing a thread dump v5.14**

If Bamboo stops responding, or is performing poorly, you should create a thread dump to help Atlassian determine the cause of the problem. This will show the state of each thread in the JVM, including a stack trace and information about what locks that thread is holding and waiting for.

**Linux (and Solaris and other Unixes) Users**

Find the process id of the JVM and issue the command:

```
Use the `ps` command to get list of all processes.
```

```
kill -3 <pid>

Linux (and Solaris and other Unixes) Users

Find the process id of the JVM and issue the command:

Use the `ps` command to get list of all processes.

```
kill -3 <pid>
```

Note: This will not kill your server (so long as you included the "-3" option, no space in between). The thread dump will be printed to Bamboo’s standard output.

Please note that some application servers (like tomcat) redirect stdout (to catalina.out for instance).

Jstack (any Platform with an JAVA JDK)

Sun JDK 1.5 and above ship with native tool called jstack to perform thread dump. To use the tool find the Process ID and execute the command:

```
jstack <ProccessID>
```

If you run your Atlassian product via wrapper (as a service) on Windows, you may encounter this error, 'Not enough storage is available to process this command'. See the suggestions in this KB article for workarounds.
Java VisualVM (any Platform with an JAVA JDK)
Oracle JDK has a native tool `jvisualvm` to perform thread dumps (and much more). To use the tool execute the command:

```
jvisualvm
```

Find Bamboo process `{{com.atlassian.bamboo.server.Server}}` and execute "Thread Dump" option available from a context menu.

Thread Dump Tools
- **Samurai**
- **Thread Dump Analyzer TDA**

### Performing a thread dump v6.2

If Bamboo stops responding, or is performing poorly, you should create a thread dump to help Atlassian determine the cause of the problem. This will show the state of each thread in the JVM, including a stack trace and information about what locks that thread is holding and waiting for.

Linux (and Solaris and other Unices) Users
Find the process id of the JVM and issue the command:

```
ps
```

Use the `ps` command to get list of all processes.

```
kill -3 <pid>
```

**Note:** This will not kill your server (so long as you included the "-3" option, no space in between). The thread dump will be printed to Bamboo's standard output.

Please note that some application servers (like tomcat) redirect stdout (to catalina.out for instance).

Jstack (any Platform with an JAVA JDK)
Sun JDK 1.5 and above ship with native tool called `jstack` to perform thread dump. To use the tool find the Proccess ID and execute the command:

```
jstack <ProccessID>
```

If you run your Atlassian product via wrapper (as a service) on Windows, you may encounter this error, 'Not enough storage is available to process this command'. See the suggestions in this KB article for workarounds.

Java VisualVM (any Platform with an JAVA JDK)
Oracle JDK has a native tool `jvisualvm` to perform thread dumps (and much more). To use the tool execute the command:

```
jvisualvm
```

Find Bamboo process `{{com.atlassian.bamboo.server.Server}}` and execute "Thread Dump" option available from a context menu.

Thread Dump Tools
- **Samurai**
- **Thread Dump Analyzer TDA**

### Performing a thread dump v6.7

If Bamboo stops responding, or is performing poorly, you should create a thread dump to help Atlassian determine the cause of the problem. This will show the state of each thread in the JVM, including a stack trace and information about what locks that thread is holding and waiting for.
Linux (and Solaris and other Unices) Users

Find the process id of the JVM and issue the command:

Use the `ps` command to get list of all processes.

```
kill -3 <pid>
```

**Note:** This will not kill your server (so long as you included the "-3" option, no space in between). The thread dump will be printed to Bamboo's standard output.

Please note that some application servers (like tomcat) redirect stdout (to catalina.out for instance).

Jstack (any Platform with an JAVA JDK)

Sun JDK 1.5 and above ship with native tool called `jstack` to perform thread dump. To use the tool find the Process ID and execute the command:

```
jstack <ProcessID>
```

When running jstack, please be sure to run it as the same user that runs the process you're targeting for thread dumps.

If you run your Atlassian product via wrapper (as a service) on Windows, you may encounter this error, 'Not enough storage is available to process this command'. See the suggestions in this KB article for workarounds.

Java VisualVM (any Platform with an JAVA JDK)

Oracle JDK has a native tool `jvisualvm` to perform thread dumps (and much more). To use the tool execute the command:

**Restoring passwords to recover admin users**

Use this document if you are unable to login as administrator or have forgotten your password and do not have Mail Server configured, to manually replace administrator passwords.

Follow the instructions for either the **External Database** or **Embedded Database**. If you have not configured a database, use the Embedded instructions.

**External Database Instructions**

**Stage One - Identify User**

The first user added is always an admin. To restore your password you simply need to update the password hash in the USERS table with the admin hash.

Connect to your database using a database admin tool such as DBVisualiser. Please download a database admin tool now if you do not have one installed already. Once installed, connect to your database and retrieve the list of administrator usernames with:

```
select * from USERS where ID=1
```
This command should list all users who belong to Bamboo-Admin user group.

Stage Two - Replace Administrator Password

Bamboo does not store passwords in plain text in the database, but uses hashes computed from the original password. You instead cut and paste a hash, rather than the plain password, over the existing password. Below is the hash for the password admin:

```
x61Ey612K12qpFL56FT9weDnpSo4AV8j8+qx2AuThdRyY036xxzTTrw10Wq3+4qQyB+XURPWx1ONxp3Y3pB37A==
```

To change the password to admin for a given username:

1. Shutdown Bamboo
2. Connect to your database. Run this SQL on your database: `select * from USERS where NAME='admin'` If you are using LDAP integration for user management (not only authentication) then your admin user will be in a different table. The SQL to run is:

```
update USERS set PASSWORD = 'x61Ey612K12qpFL56FT9weDnpSo4AV8j8+qx2AuThdRyY036xxzTTrw10Wq3+4qQyB+XURPWx1ONxp3Y3pB37A==' where NAME = 'USER_NAME_FROM_STAGE_ONE'
```
3. Start Bamboo
4. Login with your username and your password is now admin

Bamboo Password Hashing

- Before Bamboo 4.3.x the pure hashing method was used for which the hash of 'admin' is:

```
x61Ey612K12qpFL56FT9weDnpSo4AV8j8+qx2AuThdRyY036xxzTTrw10Wq3+4qQyB+XURPWx1ONxp3Y3pB37A==
```

- From Bamboo 4.3.x the salted hash is used which can be recognized by the PKCS. The hash for 'admin' using the new method is:

```
{PKCS5S2}2ji+BcvOsgM0h5QGHhc+reOU2qvyHdf20E/0caC/Lf+u3+JvEst9prD151LLpglJ
```

- However, the old hash will still work for all Bamboo versions when manually inserted into the DB.

Embedded Database Instructions

Stage One - Identify Administrator

This guide assumes that the first user added was an administrator. If this is not the case, search for the admin username and find their user id number, then modify their password hash instead.

1. Shutdown Bamboo
2. In your Bamboo home directory, open `\database\defaultdb.script` file in a text editor
3. Search for the text:

```
INSERT INTO USERS VALUES(1,'USERNAME','PASSWORD_HASH')
```

To find the administrator login entry:

```
INSERT INTO USERS VALUES(1,'USERNAME','PASSWORD_HASH')
```

Where the 1 is the user id number, and USERNAME and PASSWORD_HASH are actual values.

As an example, my table entry for user admin with password admin looks like this:
1. This step makes the administrator's password. Bamboo does not store passwords in plain text in the database, but uses hashes computed from the original password. The hash for the characters is below:

```
x61Ey612Kl2gpFL56FT9weDnpSo4AV8j8+qx2AuTHdRyY036xxzTTwr10Wq3+4qQyB+XURPWx1ONxp3Y3pB37A==
```

Paste the password hash between the " characters of their existing PASSWORD_HASH. The new administrator login entry should look like:

```
INSERT INTO USERS
VALUES(1,'USERNAME','x61Ey612Kl2gpFL56FT9weDnpSo4AV8j8+qx2AuTHdRyY036xxzTTwr10Wq3+4qQyB+XURPWx1ONxp3Y3pB37A==','EMAIL','DATE_TIME','FULL_NAME')
```

Where USERNAME is the administrator username.

2. Save the file
3. Start up Bamboo
4. Login with the administrator username and password

## Restoring passwords to recover admin users v5.14

Use this document if you are unable to login as administrator or have forgotten your password and do not have Mail Server configured, to manually replace administrator passwords.

Follow the instructions for either the Embedded Database or External Database. If you have not configured a database, use the Embedded instructions.

### Embedded Database Instructions

**Stage One - Identity Administrator**

This guide assumes that the first user added was an administrator. If this is not the case, search for the admin username and find their user id number, then modify their password hash instead.

1. Shutdown Bamboo
2. In your Bamboo home directory, open `database\defaultdb.script` file in a text editor
3. Search for the text:

```
INSERT INTO USERS VALUES(1
```

To find the administrator login entry:

```
INSERT INTO USERS VALUES(1,'USERNAME','PASSWORD_HASH')
```

Where the 1 is the user id number, and USERNAME and PASSWORD_HASH are actual values.

As an example, my table entry for user admin with password admin looks like this:
1. This step makes the administrator's password. Bamboo does not store passwords in plain text in the database, but uses hashes computed from the original password. The hash for the characters 'admin' is below:

```
x61Ey612Kl2gpFL56FT9weDnpSo4AV8j8+qx2AuTHdrY036xxzTrw10Wq3+4qQyB+XURPwx1ONxp3Y3pB37A==
```

Paste the 'admin' password hash between the '' characters of their existing PASSWORD_HASH. The new administrator login entry should look like:

```
INSERT INTO USERS
VALUES(1,'USERNAME','x61Ey612Kl2gpFL56FT9weDnpSo4AV8j8+qx2AuTHdrY036xxzTrw10Wq3+4qQyB+XURPwx1ONxp3Y3pB37A==','EMAIL','DATE_TIME','FULL_NAME')
```

Where USERNAME is the administrator username.

2. Save the file
3. Start up Bamboo
4. Login with the administrator username and password 'admin'

**External Database Instructions**

**Stage One - Identity User**

The first user added is always an admin. To restore your password you simply need to update the password hash in the USERS table with the admin hash.

Connect to your database using a database admin tool such as DBVisualizer. Please download a database admin tool now if you do not have one installed already. Once installed, connect to your database and retrieve the list of administrator usernames with:

```
select * from USERS where ID=1
```

This command should list all users who belong to Bamboo-Admin user group.

**Stage Two - Replace Administrator Password**

Bamboo does not store passwords in plain text in the database, but uses hashes computed from the original password. You instead cut and paste a hash, rather than the plain password, over the existing password. Below is the hash for the password 'admin'

```
x61Ey612Kl2gpFL56FT9weDnpSo4AV8j8+qx2AuTHdrY036xxzTrw10Wq3+4qQyB+XURPwx1ONxp3Y3pB37A==
```

To change the password to 'admin' for a given username:

1. Shutdown Bamboo
2. Connect to your database. run this SQL on your database:
```
update USERS set PASSWORD = 'x61Ey612Kl2gpFL56FT9weDnpSo4AV8j8+qx2AuTHdrY036xxzTrw10Wq3+4qQyB+XURPwx1ONxp3Y3pB37A==' where NAME = 'USER_NAME_FROM_STAGE_ONE'
```
Bamboo Password Hashing

- Before Bamboo 4.3.x the pure hashing method was used for which the hash of 'admin' is:

```
x61Ey612K12gpFL56FT9weDnpSc4AV8j8+qx2AuThdRyY036xxzTTrw10Wq3+4qQyB+XURPW x1ONxp3Y3pB37A==
```

- From Bamboo 4.3.x the salted hash is used which can be recognized by the PKCS. The hash for 'admin' using the new method is:

```
{PKCS5S2}2ji+Bcv0sgMOh5QGHHc+reOU2qvyHdf20E/0caC/Lf+u3+JvEst9prD151LLpgl J
```

- However, the old hash will still work for all Bamboo versions when manually inserted into the DB.

Restoring passwords to recover admin users v6.0

Use this document if you are unable to login as administrator or have forgotten your password and do not have Mail Server configured, to manually replace administrator passwords.

Follow the instructions for either the External Database or Embedded Database. If you have not configured a database, use the Embedded instructions.

External Database Instructions

Stage One - Identify User

The first user added is always an admin. To restore your password you simply need to update the password hash in the USERS table with the admin hash.

Connect to your database using a database admin tool such as DBVisualiser. Please download a database admin tool now if you do not have one installed already. Once installed, connect to your database and retrieve the list of administrator usernames with:

```
select * from USERS where ID=1
```

This command should list all users who belong to Bamboo-Admin user group.

Stage Two - Replace Administrator Password

Bamboo does not store passwords in plain text in the database, but uses hashes computed from the original password. You instead cut and paste a hash, rather than the plain password, over the existing password. Below is the hash for the password admin:

```
x61Ey612K12gpFL56FT9weDnpSc4AV8j8+qx2AuThdRyY036xxzTTrw10Wq3+4qQyB+XURPW x1ONxp3Y3pB37A==
```

To change the password to admin for a given username:

1. Shutdown Bamboo
2. Connect to your database, run this SQL on your database:
   ```
   select * from USERS where NAME='admin'
   ```
   If you are using LDAP integration for user management (not only authentication) then your admin user will be in a different table. The SQL to run is:
   ```
   update USERS set PASSWORD = 'x61Ey612K12gpFL56FT9weDnpSc4AV8j8+qx2AuThdRyY036xxzTTrw10Wq3+4qQyB +XURPWx1ONxp3Y3pB37A==' where NAME = 'USER_NAME_FROM_STAGE_ONE'
   ```
3. Start Bamboo
4. Login with your username and your password is now admin
Bamboo Password Hashing

- Before Bamboo 4.3.x the pure hashing method was used for which the hash of `admin` is:
  
x61Ey612K12gpFL56FT9weDnpSo4AV8j8+qx2AuTHdRyY036xxzTTrw10Wq3+4qQyB+XURPWx1ONxp3Y3pB37A==

- From Bamboo 4.3.x the salted hash is used which can be recognized by the PKCS. The hash for `admin` using the new method is:
  
  {PKCS5S2}2ji+BcvOsgMOh5QGHc+reOU2qvyHdf20E/0caC/Lf+u3+JvEst9prD151LLpgJ

- However, the old hash will still work for all Bamboo versions when manually inserted into the DB.

Embedded Database Instructions

Stage One - Identify Administrator

This guide assumes that the first user added was an administrator. If this is not the case, search for the admin username and find their user id number, then modify their password hash instead.

1. Shutdown Bamboo
2. In your Bamboo home directory, open `database\defaultdb.script` file in a text editor
3. Search for the text:

   INSERT INTO USERS VALUES(1,'USERNAME','PASSWORD_HASH')

   Where the 1 is the user id number, and USERNAME and PASSWORD_HASH are actual values.

   As an example, my table entry for user admin with password admin looks like this:

   INSERT INTO USERS
   VALUES(1,'admin','x61Ey612K12gpFL56FT9weDnpSo4AV8j8+qx2AuTHdRyY036xxzTTrw10Wq3+4qQyB+XURPWx1ONxp3Y3pB37A==','admin@admin.com','2007-08-14 11:26:18.504000000','admin')

   This step makes admin the administrator's password. Bamboo does not store passwords in plain text in the database, but uses hashes computed from the original password. The hash for the characters admin is below:

   x61Ey612K12gpFL56FT9weDnpSo4AV8j8+qx2AuTHdRyY036xxzTTrw10Wq3+4qQyB+XURPWx1ONxp3Y3pB37A==

   Paste the admin password hash between the `"` characters of their existing PASSWORD_HASH. The new administrator login entry should look like:

   INSERT INTO USERS
   VALUES(1,'USERNAME','x61Ey612K12gpFL56FT9weDnpSo4AV8j8+qx2AuTHdRyY036xxzTTrw10Wq3+4qQyB+XURPWx1ONxp3Y3pB37A==','EMAIL','DATE_TIME','FULL_NAME')
Where USERNAME is the administrator username.

2. Save the file
3. Start up Bamboo
4. Login with the administrator username and password admin

.Restoring passwords to recover admin users v6.6

Send Errors to stderr - Script Builder in Visual Studio WinXP to build Solutions Files

To display an Error Summary for erroneous builds in bamboo build summary is not available for the Script Builder - going through the build logs seems tedious.

There is a section named "Error summary" which collects all errors during the build process that are printed to stderr. For example a build script

```bash
#!/bin/bash
echo "ERROR build xyz failed" >&2
```

would print this message into the build summary section. It is up to you to insert the appropriate messages into your build script.

**Problem**

The actual problem is devenv.com/msbuild not being very helpful: both build tools only append to stdout stream, even in the case of warnings/errors during the build.

**Solution**

I solved the issue by writing a simple Ruby script that invokes the build tool and filters the stdout stream for any warnings and errors via regexp; the matching warning/error lines are then echoed to stderr and Bamboo picks them up nicely.

```ruby
pipe = IO.popen("devenv.com $#{ARGV[0]} /Rebuild ")
errors = 0
warnings = 0
while line = pipe.gets
  if line =~ /^.* : .* error .*$/
    stderr.puts line
    errors += 1
  elsif line =~ /^.* : warning .*$/
    stderr.puts line
    warnings += 1
  else
    stdout.puts line
  end
end
exit errors > 0 ? 1 : 0
```

Using Bamboo with Clover

Clover is now available as an open source project. Learn more

Getting Started
**One-click Clover Integration**

Clover reports can be activated in the Builder configuration screen. Please see Enabling the Clover add-on # Automatic Clover integration for further details.

**Would you like to view Clover Code Coverage for this plan?**

- Use Clover to collect Code Coverage for this build
- Clover is a code coverage tool that reports how well tested your code is and also highlights parts of code that require more testing.
- For more information use Atlassian Clover or view the online documentation.
- Attention: as Clover modifies your classes, ensure that you will not publish them to production - more details here.

**Integration Options**

- **Automatically integrate Clover into this build.**
- **Clover is already integrated into this build and a clover.xml file will be produced.**
- **Generate a Clover Historical Report**
- **Generate a JSON report**
  - JSON makes it very easy to integrate Clover data into a webpage.
- **Global Clover license has been configured in administration panel. To override use option below**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| Use plan-defined Clover license key | Overwrite globally defined Clover license and provide dedicated license for this plan.

To configure Clover activity refer to Clover Reference Guides for your builder:

- Clover for Ant
- Clover for Maven 2

**Classic Clover Integration**

To use Clover with Bamboo, you need to:

1. Integrate Clover with your build and ensure that HTML and XML reports are generated:
   - Clover-for-Ant Installation Guide
   - Clover-for-Maven 2 and 3 Installation Guide
2. Ensure that there are tests present in your build plan that generate test results in JUnit test report format.
3. Configure where Bamboo can find Clover reports:
   - see Enabling the Clover add-on # Manual Clover integration

For further details, please see Configuring tasks.

**Common Problems**

**Q:** I have managed to get Clover statistics displayed in numerical form for each build, but the graphs do not show a history of these statistics?
**A:** The history of Clover is displayed over time periods (e.g. a day, a week, a month), and the minimum data point is per day. The Clover coverage will not display data that is less than a day old.

**Q:** Will the Bamboo/Clover integration run on failed builds?
**A:** Before Bamboo version 1.2.1, Bamboo would only report Clover coverage for successful builds. As of Bamboo 1.2.1, Bamboo will report Clover coverage regardless of the build outcome.

**Getting gcov results in Clover coverage summary**

Clover is now available as an open source project. Learn more

This feature is not officially supported by Atlassian. It is being maintained by open source community, feel free to contribute.

**Description**

Clover does not support code coverage for C/C++. However, it is possible to display C/C++ coverage statistics on "Clover" tab on "Job Summary" and "Plan Summary" pages. In order to get this working:

- create a task in which gcov is used and produces coverage file
- create a task in which python script (see references below) converts gcov data to clover.xml file
- enable Clover on Miscellaneous tab on Job Configuration page
  - enable "Use Clover to collect code coverage for this build"
- select option "Clover is already integrated into this build and a clover.xml will be produced."
- enter path to clover.xml file
References

Source code for Python script performing conversion is kept in Mercurial bamboo-gcov-plugin repository on bitbucket.org:

hg clone ssh://hg@bitbucket.org/atlassian/bamboo-gcov-plugin

Discussion about Clover schema on Atlassian Answers:

- https://answers.atlassian.com/questions/68875/clover-xml-schema

.Collect gcov results in Clover coverage summary v5.14

This feature is not officially supported by Atlassian. It is being maintained by open source community, feel free to contribute.

A: The history of Clover is displayed over time periods (e.g. a day, a week, a month), and the minimum data point is per day. The Clover coverage will not display data that is less than a day old.

Q: Will the Bamboo/Clover integration run on failed builds?
A: Before Bamboo version 1.2.1, Bamboo would only report Clover coverage for successful builds. As of Bamboo 1.2.1, Bamboo will report Clover coverage regardless of the build outcome.

Working with Java libraries

Due to licensing restrictions, we are not allowed to re-distribute native Java libraries through our maven2 public repositories.

If you are developing plugins for Bamboo or building Bamboo from source, you might need `javax.mail` and `javax.transaction:jta:jar` for Bamboo to build successfully. The relevant POMs for this look something like this:

```
........
<dependency>
    <groupId>javax.mail</groupId>
    <artifactId>mail</artifactId>
    <version>1.3.2</version>
    <scope>compile</scope>
</dependency>
<dependency>
    <groupId>jta</groupId>
    <artifactId>jta</artifactId>
    <version>1.0.1</version>
    <scope>compile</scope>
</dependency>
........
```
Before building, please install the Oracle JAR’s into your local Maven2 repositories by following the instructions below.

**To install the `javax.mail` jar into your local Maven2 repository:**

1. Download the `javax.mail.jar` from the Oracle website.
2. Install it on your local machine by entering the following command in a terminal:

   ```bash
   mvn install:install-file -DgroupId=javax.mail -DartifactId=mail
   -Dversion=1.3.3 -Dpackaging=jar -Dfile=YOUR/PATH/TO/FILE
   
   To install into your local Maven2 repository:
   ```

**To install `javax.transaction:jta:jar` into your local Maven2 repository:**

1. Download the `javax.transaction:jta:jar` from the Oracle website.
2. Install it on your local machine by entering the following command in a terminal:

   ```bash
   mvn install:install-file -DgroupId=javax.transaction
   -DartifactId=jta -Dversion=1.0.1B -Dpackaging=jar
   -Dfile=/path/to/file
   ```

Bamboo indicates that my Ant or Maven builds failed, even though they were successful

Please note this Bamboo functionality relates only to the Maven Task and Ant Task outputs.

If your plan’s build logs indicate that your Maven or Ant builds are passing but Bamboo is reporting them as failed (or vice-versa), it could be that:

- Bamboo is not finding ‘BUILD SUCCESS’ in your build logs
- Bamboo is finding ‘BUILD FAILED’ in your build logs when it should not be doing so. (This marker is not used in Maven.)
- Your builds are returning a non-zero return code. (For example, the build log will indicate Build process for ‘ABC Application - XYZ Build’ returned with return code = 1.)

If your builds produce atypical or non-standard output, you can make Bamboo check for text other than ‘BUILD SUCCESS’ or ‘BUILD FAILED’ in your build logs. An additional system property is available to specify how far back in the logs Bamboo checks for these text markers.

<table>
<thead>
<tr>
<th>System Property</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>atlassian.bamboo.builder.success</td>
<td>Specifies the text (or string) that Bamboo looks for in the build log to determine if the build was successful</td>
<td>BUILD SUCCESS</td>
</tr>
<tr>
<td>atlassian.bamboo.builder.failedMarker</td>
<td>Specifies the text (or string) that Bamboo looks for in the build log to determine if the build failed</td>
<td>BUILD FAILED</td>
</tr>
<tr>
<td>SUCCESS_MESSAGE_LINES</td>
<td>Specifies the number of lines from the end of the build log in which to check for the values of atlassian.bamboo.builder.successMarker or atlassian.bamboo.builder.failedMarker.</td>
<td>250</td>
</tr>
</tbody>
</table>

For instructions on how to configure a system property, please refer to the Starting Bamboo page.

**Raising a request with Atlassian Support**

If you encounter any problems when setting up or using Bamboo, please let us know — we’re here to help!

You may want to search the following first:

- the [Atlassian Answers site](https://answers.atlassian.com/) (the Bamboo forum), where Atlassian staff and Bamboo users can answer your questions.
- the [Bamboo Knowledge Base](https://confluence.atlassian.com/display/DOCS/Bamboo+Knowledge+Base).

If you’ve found a bug in Bamboo, or want to request a feature or improvement, raise a ticket in the Bamboo project of our [public issue tracker](https://jira.atlassian.com). Try searching for similar issues - voting for an existing issue is quicker, and avoids duplicates.

If you still need assistance, please raise a support request, either from within Bamboo or on the Atlassian Support site, as described in the
following sections.

*Providing as much information as possible about your Bamboo installation with your initial request will help our Support Engineers to give you a faster and more complete response.*

On this page:

- Raising a Support Request from within Bamboo
- Raising a Support request yourself at Atlassian Support
- Information you should provide

### Raising a Support Request from within Bamboo

This method depends on having a [mail server configured for Bamboo](https://confluence.atlassian.com/display/BAMBOO/Configure+the+Bamboo+mail+server) that supports large zip file attachments.

1. Log in to Bamboo (as a [System Administrator](https://confluence.atlassian.com/display/BAMBOO/Configure+Bamboo+as+a+system+administrator)) and go to the admin area.
2. Click [Atlassian Support Tools](https://confluence.atlassian.com/display/BAMBOO/Support+Request) under 'System' then [Support Request](https://confluence.atlassian.com/display/BAMBOO/Support+Request).
3. Provide as much information as possible in the Description, including steps to replicate the problem, and any error messages that are appearing on the console or in the logs. For performance issues, please include profiling logs. See the section below about information you should provide.
4. Click Send.

This will produce a zip file containing the information categories selected from the list and will email this to Atlassian Support. You will receive an email advising you of details of the Support Request that was automatically created, and you will receive emailed updates about progress on your issue. You can also see the status of your request directly by visiting the [Atlassian Support System](https://confluence.atlassian.com/display/BAMBOO/Atlassian+Support+System).

### Raising a Support request yourself at Atlassian Support

1. Log in to Bamboo (as a [System Administrator](https://confluence.atlassian.com/display/BAMBOO/Configure+Bamboo+as+a+system+administrator)) and go to the admin area.
2. Click [Atlassian Support Tools](https://confluence.atlassian.com/display/BAMBOO/Support+Request) under 'System' then [Support Zip].
3. Select information categories to include in the zip file.
4. Click Create.

The zip file is created in the home directory of the Bamboo server, for example `<Bamboo_HOME>/export/Bamboo_support_2013-11-17-20-49-18.zip`.

When you now go to [Atlassian Support](https://confluence.atlassian.com/display/BAMBOO/Atlassian+Support) and create a Support Request, you can attach the Support Zip file to the request.

Please provide as much information as possible in the request, including steps to replicate the problem, and any error messages that are appearing on the console or in the logs. For performance issues, please include profiling logs. See the section below about information you should provide.

### Information you should provide

In addition to the logs and configuration information that you can include in the Support Request zip file, the following information can help to give you a faster response:

**Environment details**

- Bamboo version
- Java version (for example OpenJDK 1.7.0 JDK)
- Operating system (for example, Windows 7, Mac OS X 10.6.8)
- Database type (for example, MySQL) and version
- Browsers and versions
- Network topology - is Bamboo running behind a reverse proxy? Is that secured using HTTPS (SSL)?

**Configuration**

- Java settings, including JVM_MINIMUM_MEMORY, JVM_MAXIMUM_MEMORY

**Logs**

You may need to adjust the logging level, or enable profiling in Bamboo, in order to get more detailed logs. See [Bamboo debug logging](https://confluence.atlassian.com/display/BAMBOO/Bamboo+debug+logging).

- Debug logs – Bamboo debug logs can be found in `<Bamboo_HOME>/log`.
- Profiling logs – Bamboo profiling logs can help with analyzing performance issues and can be found in `<Bamboo_HOME>/log`.

**Performance factors**

- Number of users
- CPU spec, number of cores, whether hyperthreading is enabled
- RAM and cache sizes
Integrations

- Other Atlassian applications (and their versions)
- Which build servers are integrated with Bamboo, if any?
- Are Application Links configured?

Support Policies

Welcome to the support policies index page. Here, you'll find information about how Atlassian Support can help you and how to get in touch with our helpful support engineers. Please choose the relevant page below to find out more.

- Bamboo Support Policy
- New Features Policy
- Finding Your Bamboo Support Entitlement Number (SEN)

To request support from Atlassian, please raise a support issue in our online support system. To do this, visit support.atlassian.com, log in (creating an account if need be) and create an issue under Bamboo. Our friendly support engineers will get right back to you with an answer.

Bamboo Support Policy

This page contains details about the scope of Bamboo Support.

On this page:

- Build Failures
- Distributed Builds
- EC2
- Plugins

Build Failures

Atlassian will provide Troubleshooting Guide(s) and documentation to help customers resolve Bamboo-related issues.

Ultimately, users are responsible for the administration and maintenance of their build systems and infrastructure.

However, if the root cause of the problem is partially or wholly related to Bamboo, we will create a Bug Report or Feature request to address the issue.

Any bug or feature request reported during the course of investigation is subject to Atlassian's Bug Fixing and New Features Policies, as outlined in the Atlassian Support Offerings document.

Distributed Builds

The pre-requisites outlined in the Technical Overview section of Troubleshooting Guide must be met for server/agent communication to work.

If Atlassian determines that a customer's agent connectivity or communication problem results from a network or environmental factor, it is the customer's responsibility to address this problem and keep their network maintained.

EC2

Atlassian does not support custom elastic images (custom AMIs) and recommends using an EBS volume to customize your image if desired.

While we are happy to assist with issues related to the elastic agent, we can not help troubleshoot modifications to the Stock images which are not directly related to Bamboo functionality.

Plugins

Atlassian offers support for certain third party plugins as listed in our supported plugins list. For unsupported plugins, issues should be raised with the provider of the plugin.

The following can be classified as being third-party plugins:

- Integration with repositories other than Subversion, CVS and Perforce.
- Third party builders, test and code coverage tools other than what is shipped with Bamboo.

Each plugin's supported status is listed on its page in the Plugin Exchange.

New Features Policy

Summary

- We encourage and display your comments and votes openly in our issue tracking system, http://jira.atlassian.com.
- We don't publish roadmaps.
• Product Managers review our most popular voted issues on a regular basis.
• We schedule features based on a variety of factors.
• Our Atlassian Bug Fixing Policy is distinct from this process.
• Atlassian provides consistent updates on the top 20 issues.

How to track what features are being implemented

Cloud products

We're continuously improving and updating our cloud products. To see the latest changes that have been or are being delivered to your products, take a look at the Atlassian Cloud release notes blog.

Server products

When a new feature or improvement is scheduled, the 'fix-for' version will be indicated in the Jira issue. This happens for the upcoming release only. We maintain roadmaps for more distant releases internally, but because these roadmaps are often pre-empted by changing customer demands, we do not publish them.

How Atlassian chooses what to implement

In every major server release we aim to implement highly requested features, but it isn't the only determining factor. Other factors include:

• Customer contact: We get the chance to meet customers and hear their successes and challenges at Atlassian Summit, Atlassian Unite, developer conferences, and road shows.
• Customer interviews: All product managers at Atlassian do customer interviews. Our interviews are not simply to capture a list of features, but to understand our customers’ goals and plans.
• Community forums: There are large volumes of posts on the Atlassian Community, of votes and comments on jira.atlassian.com, and of conversations on community forums like groups on LinkedIn.
• Customer Support: Our support team provides clear insights into the issues that are challenging for customers, and which are generating the most calls to support.
• Atlassian Experts: Our Experts provide insights into real-world customer deployments, especially for customers at scale.
• Evaluator Feedback: When someone new tries our products, we want to know what they liked and disliked and often reach out to them for more detail.
• In-product feedback: The Jira Issue Collectors that we embed our products for evaluators and our Early Access Program give us a constant pulse on how users are experiencing our product.
• Usage data: Are customers using the features we have developed?
• Product strategy: Our long-term strategic vision for the product.

Please read our post on the Atlassian Community for a more detailed explanation.

How to contribute to feature development

Influencing Atlassian’s release cycle

We encourage our customers to vote on issues that have been raised in our public Jira instance, http://jira.atlassian.com. Please find out if your request already exists—if it does, vote for it. If you don’t find it, you may wish to create a new one.

Extending Atlassian products

Atlassian products have powerful and flexible extension APIs. If you would like to see a particular feature implemented, it may be possible to develop the feature as a plugin. Documentation regarding the plugin APIs is available. Advice on extending either product may be available on the user mailing-lists, or on the Atlassian Community.

If you require significant customisations, you may wish to get in touch with our partners. They specialise in extending Atlassian products and can do this work for you. If you are interested, please contact us.

Further reading

See Atlassian Support Offerings for more support-related information.

Finding Your Bamboo Support Entitlement Number (SEN)

Your Support Entitlement Number (SEN) is required when raising a support request in our Support system: http://support.atlassian.com.

See How to find your Support Entitlement Number (SEN) in the Support space for more general information about how Atlassian Support uses this number.

The three ways of finding your SEN are described below.

On this page:

• Method 1 — Check the Bamboo Administration Interface
• Method 2 — Check my.atlassian.com
• Method 3 — Check your Atlassian Invoice

Method 1 — Check the Bamboo Administration Interface

To find your SEN in the Bamboo administration interface:

1. Click the
1. Click **Overview** in the Bamboo header and choose **Overview**.

2. Click **License Details** in the left navigation panel (under "System"). The SEN is shown, as in the screenshot below:

![License Details](image)

Method 2 — Check my.atlassian.com

To find your SEN via my.atlassian.com:

1. Log into my.atlassian.com as the Account Holder or Technical Contact for your Bamboo product.
2. The SEN will be shown, as per the screenshot below:
Method 3 — Check your Atlassian Invoice

Your Support Entitlement Number (SEN) appears on the third page of your Atlassian Invoice.

Bamboo resources

**Resources for Evaluators**

- default repository
- elastic agent
- elastic Bamboo
- elastic block store
- elastic image
activity log
Every plan has an activity log. An activity log is a temporary display of the latest output from the plan's most recent build log.

agent
A Bamboo agent is a service that can run job builds. There are the following types of Bamboo agents:

- local agents run as part of the Bamboo server.
- remote agents run on computers, other than the Bamboo server, that run the remote agent tool.
- elastic agents run in the Amazon Elastic Compute Cloud (EC2).

Local agents run in the Bamboo server's process, i.e. in the same JVM as the server. Each remote agent runs in its own process, i.e. has its own JVM.

Each agent has a defined set of capabilities and can only run builds for jobs whose requirements match the agent's capabilities.

agent-specific capability
An agent-specific capability is a capability that applies to one agent only. Note that the value of an agent-specific capability will override the value of a shared capability of the same name (if one exists).

See
Agents and capabilities and

Configuring capabilities for more information.

artifact

Artifacts are files created by a job build (e.g. JAR files). Artifact definitions are used to specify which artifacts to keep from a build and are configured for individual jobs.

See Sharing artifacts.

authors in Bamboo

An author is any person who checks in code to a repository that is associated with a Bamboo plan. An author need not be a Bamboo user.

See Generating reports on selected authors.

build

A build is the execution of either a plan or a job. The execution of a plan is referred to as a 'plan build' and that of a job is a 'job build'.

build activity

Build activity is the number of builds that occur in a given period of time.

build duration

Build duration is the total time taken to execute a plan - from the time the plan is dispatched till the plan is finished and the build results are processed.

Variations in a plan's build duration can be over time.

build log

Every build has a build log. A build log is a permanent record of all the output generated by compiling the job's source-code and executing the tests.

build queue

The Bamboo build queue controls the sequence of builds. When a plan submits a build to the build queue, the build will wait in the build queue until a suitable agent is available to run the build.

The build queue is displayed on the Build Activity tab of the Dashboard.

build result

Every completed build has a build result:

- 'Successful' — the code compiled, with or without errors, and all tests completed successfully.
- 'Failed' — either the code did not compile, or at least one test failed.
- 'Incomplete' — the build was not completed, e.g. it may have been stopped manually.

Additionally,

- if the build result is 'Failed', and the previous build result was 'Successful', the build is said to be 'Broken'.
- if the build result is 'Successful', and the previous build result was 'Failed', the build is said to be 'Fixed'.

build telemetry

Build telemetry is the insight provided by Bamboo's dynamic reports, charts and collation of build metrics. Build telemetry helps identify trends across build plans and across authors — not just focusing on the results of a single build.

capability

A capability is a feature of an agent. A capability can be defined on an agent for:

- an executable (e.g. Maven)
- a JDK
- a Version Control System client application (e.g. Git)
- a custom capability. This is a key-value property which defines a particular characteristic of an agent (e.g. 'operating.system=WindowsXP' or 'fast.builds=true').

Capabilities typically define the path to an executable that has already been installed, and must be defined in Bamboo before Bamboo or its agents can make use of those.

Capabilities can be defined specifically for an agent, or they can be shared between either all local agents or all remote agents. Note that the value of an agent-specific capability overrides the value of a shared capability of the same name (if one exists).

See Configuring capabilities for more information.
A child is a plan which gets triggered when another plan completes a build. See Setting up plan build dependencies.

committer

A committer is the Bamboo user(s) who committed code to a particular build (i.e. someone who committed code after the previous build was checked out by Bamboo).

Administrators can configure a plan's notifications to be sent to the build's committer(s).

custom capability

Custom capabilities can be used to control which jobs will be built by a particular agent, since agent capabilities are required to match job requirements. For example, if the builds for a particular job should only run in a Windows environment, you could create a custom capability 'operating.system=WindowsXP' for the appropriate agent(s), and specify it as a requirement for this job.

- To create a new custom capability in your Bamboo system, see Defining a new custom capability.
- To specify a job's requirement for a custom capability, see Configuring a job's requirements.

default repository

The first repository in the list of plan repositories is the Plan's Default Repository. The default repository will be automatically checked out by any new job created.

Repository specific Plan Variables, such as repository.revision.number, will point to the default repository of a Plan. To address a specific repository, you must add the name of the repository to the end of the variable as follows: repository.revision.number.product_core.

elastic agent

An elastic agent is an agent that runs in the Amazon Elastic Compute Cloud (EC2). An elastic agent process runs in an elastic instance of an elastic image. An elastic agent inherits its capabilities from the elastic image that it was created from.

elastic Bamboo

Elastic Bamboo allows you to use computing resources from the Amazon Elastic Compute Cloud (EC2) to run builds. Elastic Bamboo uses a remote agent AMI (Amazon Machine Image) to create instances of remote agents in the Amazon EC2.

elastic block store

The Amazon Elastic Block Store (EBS) provides 'EBS volumes' which can attach to EC2 instances. EBS volumes (and the 'EBS snapshots' created from these volumes) provide persistent storage for your elastic instances.

If you have relatively static resources required for building your Bamboo jobs (such as, source code checkouts and Maven repository artifacts), you can add these to an EBS volume. From this volume, you can create an EBS snapshot, which effectively records the 'state' of an EBS volume at a given point in time.

elastic image

An elastic image is an Amazon Machine Image (AMI) that is stored in one of Amazon data centers for use with the Elastic Bamboo feature. An elastic image is used to create elastic instances, which in turn create elastic agents. Conceptually, an elastic image is equivalent to an operating system running on a computer's boot hard drive and elastic instances would be the software that runs on this operation system.

Each elastic image registered with the Amazon Web Services (AWS) has its own unique identifier, known as an AMI ID.

You can associate multiple elastic images with a Bamboo server. One default shared image is maintained by Atlassian in AWS, and is available to all Elastic Bamboo users.

You can also create your own custom elastic images.

elastic instance

An elastic instance is a running instance of an elastic image. One elastic instance is created whenever an elastic image is started. Hence, starting one elastic image multiple times, results in the creation of multiple elastic instances. Each time an elastic instance is created, one ela
elastic agent is created on that instance.

Conceptually, an elastic instance can be thought of as a computer. The elastic agent’s processes are run on this computer and the elastic image is the boot hard drive. Unlike computers, however, elastic instances are temporary and stateless. When an elastic instance is shut down:

- Any changes that an elastic instance makes to the boot hard drive (e.g. agent log file) will not persist
- Any customizations to the instance itself will also be lost.

The Amazon Elastic Block Store can provide persistent storage for your elastic instances.

executable

An executable is an external program that Bamboo uses during the build process. Generally, executables compile source code to generate compiled executable files (referred to as artifacts in Bamboo). Ant, Maven, MSBuild or PHPUnit are just some examples of executables that can be used as part of your build process.

New executables can be defined as capabilities in Bamboo. Once an executable has been defined in Bamboo, it can be configured as part of a task.

See Defining a new executable capability.

favorites

Each Bamboo user can nominate their favorite plans — that is, the plans they work with the most.

Each user’s favorites are displayed on the ‘My’ page of the Dashboard. Bamboo administrators can also configure each plan to send build result notifications to users who have nominated the plan as one of their favorites (these users are known as the plan’s watchers).

global permission

A global permission is the ability to perform a particular operation in relation to Bamboo as a whole. See Granting global permissions to users or groups.

See also plan permission.

job

A Bamboo job is a single build unit within a plan. One or more jobs can be organized into one or more stages. The jobs in a stage can all be run at the same time, if enough Bamboo agents are available. A job is made up of one or more tasks.

A job:

- Processes a series of one or more tasks that are run sequentially on the same agent.
- Controls the order in which tasks are performed.
- Collects the requirements of individual tasks in the job, so that these requirements can be matched with agent capabilities.
- Defines the artifacts that the build will produce.
- Can only use artifacts produced in a previous stage.
- Specifies any labels with which the build result or build artifacts will be tagged.

Each new plan created in Bamboo contains at least one job known as the 'Default Job'.

Projects and plans can only be configured by Bamboo administrators (see Creating a plan).

label

A label is a convenient way to tag and group build results that are logically related to each other. Labels can also be used to define RSS feeds.

Labels can be applied to build results automatically, by specifying the label(s) in a plan (note that only Bamboo administrators can do this). Labels can also be applied to build results manually by Bamboo users.

local agent

See agent.

parent

A parent is a plan which triggers another plan to build whenever it completes a build. See Setting up plan build dependencies.

permission

See plan permission and global permission.

plan

A plan defines everything about your continuous integration build process in Bamboo.

A plan:

- Has a single stage, by default, but can be used to group jobs into multiple stages.
- Processes a series of one or more stages that are run sequentially using the same repository.
- Specifies the default repository.
• Specifies how the build is triggered, and the triggering dependencies between the plan and other plans in the project.
• Specifies notifications of build results.
• Specifies who has permission to view and configure the plan and its jobs.
• Provides for the definition of plan variables.

Every plan belongs to a project.

Projects and plans can only be configured by Bamboo administrators (see Creating a plan).

**plan permission**

A plan permission is the ability to perform a particular operation on a plan and its jobs. For each plan, different permissions can be granted to particular groups and/or users.

See Configuring a plan’s permissions and Granting plan permissions in bulk.

See also global permission.

**projects in Bamboo**

A project is a collection of plans. Projects enable you to easily group and identify plans which are logically related to each other. They are especially useful when generating reports across multiple plans.

A project:
• Has one, or more, plans.
• Provides reporting (using the wallboard, for example) across all plans in the project.
• Provides links to other applications.

Projects are created from the create plan screen. Select New Project from the project drop down when creating a new plan.

A project is a collection of plans. Projects enable you to easily group and identify plans which are logically related to each other. They are especially useful when generating reports across multiple plans.

A project:
• Has one, or more, plans.
• Provides reporting (using the wallboard, for example) across all plans in the project.
• Provides links to other applications.

Projects are created from the create plan screen. Select New Project from the project drop down when creating a new plan.

A project is a collection of plans. Projects enable you to easily group and identify plans which are logically related to each other. They are especially useful when generating reports across multiple plans. For example, you can control access to your projects easily by using project-level permissions.

A project:
• Has none, one, or more, plans.
• Provides reporting (using the wallboard, for example) across all plans in the project.
• Provides links to other applications.
• Allows setting up permissions for all the plans it contains

Projects are created from the create plan screen. Select New Project from the project dropdown when creating a new plan.

If you’re using repository-stored specs in Bamboo, you can define which repositories may have access to your projects.

A project is a collection of plans. Projects enable you to easily group and identify plans which are logically related to each other. They are especially useful when generating reports across multiple plans. For example, you can control access to your projects easily by using project-level permissions.

A project:
• Has none, one, or more, plans.
• Provides reporting (using the wallboard, for example) across all plans in the project.
• Provides links to other applications.
• Allows setting up permissions for all the plans it contains

Projects are created from the create plan screen. Select New Project from the project dropdown when creating a new plan.

If you’re using repository-stored specs in Bamboo, you can define which repositories may have access to your projects.

queue

See build queue.

reason
A build's reason is the way in which the build was triggered. Triggering in Bamboo allows plan builds to be started automatically. Bamboo has the following trigger methods:

- **Polling the repository for changes** — Bamboo polls the source repository for changes, either periodically or according to a schedule. This ensures that a plan build only runs when code has changed in the plan's source repository.
- **Repository triggers the build when changes are committed** — Requires that your source repository is configured to fire an event to Bamboo. This has the advantage of placing minimal load on your Bamboo server.
- **Cron-based scheduling** — Builds are run according to a schedule, regardless of whether any code changes have occurred. This can allow a team to structure the day according to a predictable schedule.
- **Single daily build** — The build is run at a specified time every day.

For more information, see Triggering builds.

**remote agent**

See agent.

See also the Bamboo remote agent installation guide.

**remote agent supervisor**

A *remote agent supervisor* is an application that is installed alongside a Bamboo remote agent, by default. The remote agent supervisor is an implementation of the [Java Service Wrapper](https://service-wrapper.sourceforge.net/).

The remote agent supervisor monitors remote agents on the machine that it is installed on. If any remote agent crashes, the remote agent supervisor will automatically attempt to restart it. If communications are lost with the Bamboo server, the remote agent will shut itself down and wait for the remote agent supervisor to restart it.

The remote agent supervisor will run on the following operating systems:

- **Linux**:
  - x86
  - x86_64
  - IA64
  - PPC 64 bit (*but not* 32 bit)
- **Mac OSX**: all architectures
- **Solaris**:  
  - x86
  - x86_64 (running in 32 bit mode)
  - IA64 (running in 32 bit mode)
  - SPARC (both 32 bit and 64 bit)
- **Windows**:  
  - 32 bit
  - 64 bit

**requirement**

A *requirement* is specified in a *job* or a *task*. A requirement specifies a *capability* that an *agent* must have for it to *build* that job or task. A job inherits all of the requirements specified in its tasks.

Together, capabilities and requirements control which agents can execute builds for particular *jobs*. Each job can only be built by agents whose capabilities match the job's requirements. See Configuring a job's requirements for more information.

**shared capability**

Shared capabilities are inherited by all applicable agents, that is, (shared) local server capabilities are inherited by all local agents, and shared remote capabilities are inherited by all remote agents. Note, however, that the value of a shared capability will be overridden by the value of an *agent-specific capability* of the same name (if one exists).

See:

Agents and capabilities and Configuring capabilities.

**stage**

*Stages* group (or 'map') *jobs* to individual steps within a plan's *build process*. For example, you may have an overall plan build process that comprises a compilation step, followed by several test steps, followed by a deployment step. You can create separate Bamboo stages to represent each of these steps.

A stage:
- Has a single job, by default, but can be used to group multiple jobs.
- Processes its jobs in parallel, on multiple agents (where available).
- Must successfully complete all its jobs before the next stage in the plan can be processed.
- May produce artifacts that can be made available for use by a subsequent stage.

Each new plan created in Bamboo contains at least one stage (for the default job) and is known as the 'Default Stage'. Stages can only be configured by Bamboo administrators.

Stock images

This page describes the latest available stock elastic images. The previously released elastic images are still available.

For more information about how to get a list of stock images available for your Bamboo version, see Viewing the list of Bamboo stock images.

Atlassian maintains public 'default' elastic images, which are currently available as follows:

<table>
<thead>
<tr>
<th>Operating system</th>
<th>AWS availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ubuntu</td>

## Windows stock image

The Windows stock image is built from:

- the Windows Server 2012 R2 Standard 64-bit operating system, with all updates applied.
- the Bamboo elastic agent.
Note that:

- the elastic agents now run on Java JDK 8.
- the image now uses Git for Windows and its SSH.
- support for MSBuild 2.0 and 3.5 has been removed.

The Windows stock image has the following default packages and capabilities:

<table>
<thead>
<tr>
<th>Default packages/capabilities</th>
<th>Path/value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Builders</strong></td>

</tbody>
</table>
Notes

Be aware that the default packages and capabilities listed above may change with each major release of Bamboo. There is a new default image (with its own AMI ID) for each new version of Bamboo. However, older default images will still be available for use.

**stock images v5.14**

This page describes the latest available stock elastic images. The previously released elastic images are still available.

For more information about how to get a list of stock images available for your Bamboo version, see [Viewing the list of Bamboo stock images](#).

Atlassian maintains public ‘default’ elastic images, which are currently available as follows:

<table>
<thead>
<tr>
<th>Operating system</th>
<th>AWS availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ubuntu</td>
<td>All regions</td>
</tr>
<tr>
<td>Windows 2012</td>
<td>All regions</td>
</tr>
<tr>
<td>Amazon Linux</td>
<td>US East region</td>
</tr>
</tbody>
</table>

All stock images in Bamboo use Java 8 for the system Java.

Bamboo’s Elastic Bamboo feature uses these images by default. In your list of elastic image configurations, an image will have '(stock image)' appended to its name.

---

**Amazon Linux/Ubuntu stock image**

The stock images available for Bamboo contain one of the following operating systems:

- Amazon Linux
- Ubuntu

as well as the Bamboo elastic agent.

The images have the following default packages and capabilities:

<table>
<thead>
<tr>
<th>Default packages/capabilities</th>
<th>Path/value</th>
</tr>

### Windows stock image

The Windows stock image is built from:

- the Windows Server 2012 R2 Standard 64-bit operating system, with all updates applied.
- the Bamboo elastic agent.

Note that:

- the elastic agents now run on Java JDK 8.
- the image now uses Git for Windows and its SSH.
- support for MSBuild 2.0 and 3.5 has been removed.

The Windows stock image has the following default packages and capabilities:
Grails 2.2 | C:\opt\grails-2.2
Grails 2.3 | C:\opt\grails-2.3
Grails 2.4 | C:\opt\grails-2.4
Maven 2.0 | C:\opt\maven-2.0
Maven 2.1 | C:\opt\maven-2.1
Maven 2.2 | C:\opt\maven-2.2
Maven 3.0 | C:\opt\maven-3.0
MSBuild 4.0 (32bit) | C:\Windows\Microsoft.NET\Framework\v4.0.30319\MSBuild.exe
MSBuild 4.0 (64bit) | C:\Windows\Microsoft.NET\Framework64\v4.0.30319\MSBuild.exe
NAnt 0.92 | C:\opt\nant-0.92

**JDKs**

JDK 6 | C:\opt\jdk-6
JDK 7 | C:\opt\jdk-7
JDK 8 | C:\opt\jdk-8

**Browsers**

Firefox 10 | C:\Program Files (x86)\Mozilla Firefox
Internet Explorer 9 | C:\Program Files (x86)\Internet Explorer

**Other**

Git (Cygwin Git 2.1) | C:\Program Files (x86)\Git\bin\git.exe
Mercurial 3.2 | C:\Program Files\TortiseHg\hg.exe
Node.js 0.10 | c:\opt\node-0.10
PHP 5.3 (with xdebug support) | c:\opt\php-5.3
PHPUnit 4.4.1 | c:\opt\phpunit-4.4

**Notes**

Be aware that the default packages and capabilities listed above may change with each major release of Bamboo. There is a new default image (with its own **AMI ID**) for each new version of Bamboo. However, older default images will still be available for use.

For more information about how to get a list of stock images available for your Bamboo version, see Viewing the list of Bamboo stock images.

Atlassian maintains public 'default' elastic images, which are currently available as follows:

</table>
All stock images in Bamboo use Java 8 for the system Java.

Bamboo’s Elastic Bamboo feature uses these images by default. In your list of elastic image configurations, an image will have '(stock image)' appended to its name.

On this page:
- Amazon Linux/Ubuntu stock image
- Windows stock image
- Notes

Amazon Linux/Ubuntu stock image

The stock images available for Bamboo contain one of the following operating systems:
- Amazon Linux
- Ubuntu

as well as the Bamboo elastic agent.

The images have the following default packages and capabilities:

<table>
<thead>
<tr>
<th>Default packages/capabilities</th>
<th>Path/value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Builders</td>
<td></td>
</tr>
<tr>
<td>Ant 1.8</td>
<td>/opt/ant-1.8</td>
</tr>
<tr>
<td>Ant 1.9</td>
<td>/opt/ant-1.9</td>
</tr>
<tr>
<td>Grails 1.3</td>
<td>/opt/grails-1.3</td>
</tr>
<tr>
<td>Grails 2.0</td>
<td>/opt/grails-2.0</td>
</tr>
<tr>
<td>Grails 2.1</td>
<td>/opt/grails-2.1</td>
</tr>
<tr>
<td>Grails 2.2</td>
<td>/opt/grails-2.2</td>
</tr>
<tr>
<td>Grails 2.3</td>
<td>/opt/grails-2.3</td>
</tr>
<tr>
<td>Grails 2.4</td>
<td>/opt/grails-2.4</td>
</tr>

</table>

**Other**

- AWS CLI
- Bash (Command) /bin/bash
- Docker
- The latest version supplied with your Linux distribution, might be different for Amazon, Linux, and Ubuntu. /usr/bin/docker
- Git /usr/bin/git
- Mercurial /usr/bin/hg
- Node.js
- Node 0.12.18
- Node 4.7.2
- Node 6.9.4
- PHPUnit 3.7 /opt/phpunit-3.7
- PHPUnit 4.4 /opt/phpunit-4.4

**Windows stock image**

The Windows stock image is built from:
- the Windows Server 2012 R2 Standard 64-bit operating system, with all updates applied.
- the Bamboo elastic agent.

Note that:
- the elastic agents now run on Java JDK 8.
- the image now uses Git for Windows and its SSH.
- support for MSBuild 2.0 and 3.5 has been removed.

The Windows stock image has the following default packages and capabilities:

<table>
<thead>
<tr>
<th>Default packages/capabilities</th>
<th>Path/value</th>
</tr>
</thead>
<tbody>

</table>

**Notes**

Be aware that the default packages and capabilities listed above may change with each major release of Bamboo. There is a new default image (with its own AMI ID) for each new version of Bamboo. However, older default images will still be available for use.

**task**

A task:

- Is a small discrete unit of work, such as source code checkout, executing a Maven goal, running a script, or parsing test results.
- Is run sequentially within a job on a Bamboo working directory.

Tasks may make use of an executable if required. Tasks are configured within the scope of a job. A job can be configured to execute a number of tasks, on the same working directory. For example, before executing a Maven goal, the user could substitute specific files within the working directory, substitute version numbers, check out source repositories, or execute a script.

Final tasks for a job are always executed, even if previous tasks in the job failed.

**triggering**

Triggering in Bamboo allows plan builds to be started automatically. Bamboo has the following trigger methods:

- **Polling the repository for changes** — Bamboo polls the source repository for changes, either periodically or according to a schedule. This ensures that a plan build only runs when code has changed in the plan’s source repository.
- **Repository triggers the build when changes are committed** — Requires that your source repository is configured to fire an event to Bamboo. This has the advantage of placing minimal load on your Bamboo server.
Cron-based scheduling — Builds are run according to a schedule, regardless of whether any code changes have occurred. This can allow a team to structure the day according to a predictable schedule.

Single daily build — The build is run at a specified time every day.

For more information, see Triggering builds.

**watcher**

A plan’s watchers are the Bamboo users who have marked this plan as one of their favorites. Administrators can configure a plan’s notifications to be sent to the plan’s watchers.

**Contributing to the Bamboo documentation**

Would you like to share your Bamboo hints, tips and techniques with us and with other Bamboo users? We welcome your contributions.

**Blogging your technical tips and guides**

Have you written a blog post describing a specific configuration of Bamboo or a neat trick that you have discovered? Let us know, and we will link to your blog from our documentation.

**Contributing documentation in other languages**

Have you written a guide to Bamboo in a language other than English, or translated one of our guides? Let us know, and we will link to your guide from our documentation.

**On this page:**

- Blogging your technical tips and guides
- Contributing documentation in other languages
- Updating the documentation itself
  - Getting permission to update the documentation
  - Our style guide
  - How we manage community updates

**Related pages:**

- Author Guidelines
- Atlassian Contributor License Agreement

**Updating the documentation Itself**

Have you found a mistake in the documentation, or do you have a small addition that would be so easy to add yourself rather than asking us to do it? You can update the documentation page directly.

**Getting permission to update the documentation**

Please submit the Atlassian Contributor License Agreement.

**Our style guide**

Please read our short guidelines for authors.

**How we manage community updates**

Here is a quick guide to how we manage community contributions to our documentation and the copyright that applies to the documentation:

- **Monitoring by technical writers.** The Atlassian technical writers monitor the updates to the documentation spaces, using RSS feeds and watching the spaces. If someone makes an update that needs some attention from us, we will make the necessary changes.

- **Wiki permissions.** We use wiki permissions to determine who can edit the documentation spaces. We ask people to sign the Atlassian Contributor License Agreement (ACLA) and submit it to us. That allows us to verify that the applicant is a real person. Then we give them permission to update the documentation.

- **Copyright.** The Atlassian documentation is published under a Creative Commons CC BY license. Specifically, we use a Creative Commons Attribution 2.5 Australia License. This means that anyone can copy, distribute and adapt our documentation provided they acknowledge the source of the documentation. The CC BY license is shown in the footer of every page, so that anyone who contributes to our documentation knows that their contribution falls under the same copyright.

.Hello World in CASC

.Part 1 - Creating a simple project v6.0

This tutorial will show you how to create a simple project containing Bamboo Specs (plan configuration written as code) and next execute it to create a plan in Bamboo. You use a Maven archetype to create a skeleton and next add a simple script task.

Prerequisites
In order to walk through this tutorial you need to install:

- JDK 8 or higher
- Maven 3 or higher
- Eclipse or IntelliJ IDEA IDE
  - you may also use a different IDE, but tutorial provides examples for the two above
- Bamboo 6.0 or higher

Step 1: Create a Maven project using archetype

Execute the following Maven archetype to create a skeleton of the project:

```
mvn archetype:generate -B \
-DarchetypeGroupId=com.atlassian.bamboo \
-DarchetypeArtifactId=bamboo-specs-archetype \
-DarchetypeVersion=5.16.25 \
-DgroupId=com.atlassian.bamboo -DartifactId=bamboo-specs-tutorial \
-Dversion=1.0.0-SNAPSHOT \ 
-Dpackage=tutorial -Dtemplate=minimal
```

Explanation of options used ...
- the archetypeGroupId, archetypeArtifactId and archetypeVersion identify the Bamboo archetype
- the groupId, artifactId, version properties identify the project you want to create
- the package is a Java package prefix which shall be used in the project
- the template parameter lets you choose code to be generated ('minimal' is for the purpose of this tutorial)

The project will be created in bamboo-specs-tutorial directory:

```
cd bamboo-specs-tutorial
```

Step 2: Import the project into IDE

You can now import the project into your IDE.

How to import into Eclipse ...
1. Run Eclipse.
2. Select the "File > Import ..." from the main menu.
3. In the Import dialog select the "Maven > Existing Maven Projects" and click "Next".
4. On the next wizard page click "Browse ...", point to the bamboo-specs-tutorial folder and click "Open".
5. On the list of Projects you shall see the com.atlassian.bamboo:bamboo-specs-tutorial. Click the "Finish" button.
6. Eclipse will create a new project and download necessary dependencies (it may take a minute or so).

How to import into IntelliJ IDEA ...
1. Run IntelliJ IDEA.
2. Select "File > Open" from the main menu and select the pom.xml file.
3. In the dialog "pom.xml is a project file. Would you like to open this project?" click the "Open as Project" button.
4. IntelliJ IDEA will create a new project and download necessary dependencies (it may take a minute or so).

Open the src/main/java/tutorial/PlanSpec.java file and have a look how it is structured:

- the class is named PlanSpec, but you can use any class name you want
- it is annotated with the BambooSpec annotation
  - this annotation is used by the spec-runner Maven plugin to find classes containing Bamboo plans
- it has the main method, so you can run it as a normal Java application
- it uses Bambooserver class to publish a plan using password authentication (user name and password are read from the '.credentials' file from current working directory)

Step 3: Define a job with a script task
In the `createPlan` method put a cursor after the `description` method call:

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
        .description("Plan created from (enter repository url of your plan)");
}
```

Type `.` and let your IDE show you available options:

Pick the `stages` method and add `new Stage("Stage 1")` constructor call inside method's argument.

Next, add a job to the stage using the `jobs` method and `new Job()` constructor. Name the job "Build & run".

```java
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
        .description("Plan created from (enter repository url of your plan)")
        .stages(
            new Stage("Stage 1")
            .jobs(new Job("Build & run", "RUN")))
    }
```

Now, let's add a task to the job. Type `.tasks()` and declare a `new ScriptTask()` inside as shown below. Call `.InlineBody` on the ScriptTask:
private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
        .description("Plan created from (enter repository url of your plan")
        .stages(
            new Stage("Stage 1")
                .jobs(new Job("Build & run", "RUN")
                    .tasks(
                        new ScriptTask().inlineBody("echo Hello world!"))));
}

Using an IDE (such as Eclipse or IntelliJ IDEA) can greatly improve your productivity, thanks to features such as:
- code autocompletion (names of classes, methods)
- inline help (method's arguments, JavaDocs)
- code compilation and syntax checking

Step 4: Validate Bamboo Specs offline

As you can see, validation fails because the job name contains an invalid '&) character:

    com.atlassian.bamboo.specs.api.exceptions.PropertiesValidationException:

    Chain or job's name can not contain any of those characters: [", ", ", ", <, >, \]

Let's correct the job name and remove "&" character. Your code should look like this:

private Plan createPlan() {
    return new Plan(
        project(),
        "Plan Name", "PLANKEY")
        .description("Plan created from (enter repository url of your plan")
        .stages(
            new Stage("Stage 1")
                .jobs(new Job("Run", "RUN")
                    .tasks(
                        new ScriptTask().inlineBody("echo Hello world!"))));
}

- How to run from Maven ...
  mvn test

- How to run from an IntelliJ IDEA ...
1. Right click on the PlanSpecTest class in the "Project" view.
2. Select "Run PlanSpecTest".

**How to run from Eclipse ...**
1. Select "Run > Run configurations ..." from the main menu.
2. Select "Java application" and click the "New launch configuration" button.
3. Select PlanSpec in the "Main class" field.
4. Click "Run".

**Step 5: Publish Bamboo Specs to Bamboo server**

Ensure that your Bamboo instance is up and running.

**About URL and credentials ...**
In the steps below we assume that Bamboo runs on your local machine: `http://localhost:8085`. In case not, change the bambooUrl variable in the main method. In the steps below we assume that you have an administrator account with "admin" username and "admin" password. In case not, update the .credentials file located in project's root directory.

Bamboo performs validation of the plan sent. So let's check if your Bamboo Specs is valid and let's send the plan:

**How to run from Maven ...**
The pom.xml contains the 'publish' profile which executes the spec-runner Maven plugin in the "install" phase. So just type:

```
mvn install -Ppublish
```

**How to run from Eclipse ...**
1. Select "Run > Run configurations ..." from the main menu.
2. Select "Java application" and click the "New launch configuration" button.
3. Select PlanSpec in the "Main class" field.
4. Click "Run".

**How to run from a IntelliJ IDEA ...**
1. Right click on the PlanSpec class in the "Project" view.
2. Select "Run PlanSpec.main()".

Let's send the plan again. This time it succeeds with the console output like this:

```
Executing request POST http://localhost:8085/rest/api/latest/import/plan
HTTP/1.1
OK http://localhost:8085/browse/PROJ-PLANKEY
```

Bamboo together with the "OK" response returns URL of the created plan. Open this URL, select "Actions" > "Configure plan" and check that the stage contains a job with the "Hello World" Script Task.

**Summary**

In the first part of this tutorial you've learned how to quickly create a template project for Bamboo Spec, extend it and send the plan to Bamboo to have it created for you.

**Next steps**

Jump straight to the reference documentation and Bamboo Specs API JavaDocs to start coding your own Bamboo Spec.
How to...
.How to... v6.0

This page should contain step-by-step procedures that will tell users how to perform tasks with CasC.

Part 2 - Creating a build matrix
.Part 2 - Creating a build matrix v6.0

In the second part of tutorial you will learn how to set up a matrix build, containing of multiple plans and jobs. Such matrix can be useful to test a product in different environments, such as operating systems, databases or web browsers. Thanks to a fact that a high-level language (Java) is used to define configuration, you can reuse much of the code.

Prerequisites

Perform all steps from Part 1 - Creating a simple project.

Step 6: Create several plans at once

Let’s imagine that you’d like to test the product on three operating systems: “OSX”, “UNIX”, “WIN”. How to do this? You could define three distinct plans, for instance.

First, in the main method add a for loop iterating over three operating systems. Next, in the loop create a plan using the topLevelPlan method and execute it using a runner. Your code might look like this:

```java
public static void main(final String[] args) throws Exception {
    final Runner runner = createRunner(args.length > 0 ? args[0] : "--publish");
    for (String os : Arrays.asList("OSX", "UNIX", "WIN")) {
        final Plan topLevelPlan = new PlanSpec().topLevelPlan();
        runner.run(bambooUrl, topLevelPlan);
    }
}
```

Note that the code above creates the same plan three times. This is because a plan key is the same. Let add the planName and planKey attributes for the topLevelPlan method to parameterise it. Example:
private Plan topLevelPlan(String planName, String planKey) {
    return new Plan(
        project(),
        planName, planKey)
            .withDescription("Plan created from (enter repository url of your plan")
            .withStages(
                new Stage("Stage 1")
                    .withJobs(new Job("Run", "RUN")
                        .withTasks(new ScriptTask().withInlineBody("echo Hello world!"))
                    )
            );
}

We can include the operating system name in plan’s name and key. Example:

public static void main(final String[] args) throws Exception {
    final Runner runner = createRunner(args.length > 0 ? args[0] : "--publish");

    for (String os : Arrays.asList("OSX", "UNIX", "WIN")) {
        final Plan topLevelPlan = new PlanSpec().topLevelPlan("Plan for " + os, os);
        runner.run(bambooUrl, topLevelPlan);
    }
}

Execute the PlanSpec and publish it to your Bamboo instance. In the console output you shall see:

Executing request POST http://localhost:8085/rest/api/latest/import/plan
HTTP/1.1
OK
Executing request POST http://localhost:8085/rest/api/latest/import/plan
HTTP/1.1
OK
Executing request POST http://localhost:8085/rest/api/latest/import/plan
HTTP/1.1
OK

Open your Bamboo server and check that three plans have been created.

In a real-world scenario you would need build agents with different operating systems installed and add a proper requirement for a job.

You can learn more about agents and capabilities here.
Step 7: Create a plan with multiple parallel jobs

Let's imagine that you would like to not only test against different operating systems, but also against different databases: HSQLDB, MS SQL, MySQL and Postgres. Let's imagine that you don't want to create even more plans for this purpose. How this could be achieved? You could leverage jobs for this purpose, for instance. Every plan can consist of multiple jobs, all of them will be running in parallel.

Let's refactor the `topLevelPlan` method. First, extract the `ScriptTask` to a local variable and use this variable in `Job().tasks()` call.

Next, create a collection of jobs using the following databases: "HSQLDB", "MSSQL", "MYSQL" and "POSTGRES" and store in a local variable. You can use database name in job's name and key. **Hint:** you can use the `Stream.of().map().collect()` for this purpose.

Finally, use a collection of jobs in `Stage().jobs()`. Your code should be similar to the following:

```java
private Plan topLevelPlan(String planName, String planKey) {
    ScriptTask task = new ScriptTask().inlineBody("echo Hello world!");
    Collection<Job> jobs = Stream
        .of("HSQLDB", "MSSQL", "MYSQL", "POSTGRES")
        .map(db -> new Job("Run with " + db, db).tasks(task))
        .collect(Collectors.toList());
    return new Plan(project(), planName, planKey)
        .description("Plan created from (enter repository url of your plan)")
        .stages(new Stage("Stage 1")
                .jobs(jobs));
}
```

Execute the PlanSpec and publish it to your Bamboo instance. Check that three plans have been updated and they now contain four jobs each.

Stages run sequentially within a plan, jobs run in parallel within a stage, tasks run sequentially within a job.

You can learn more about Bamboo plan structure here.

Step 8: Use job requirements to run with different environments

**TODO** requirement for a property + requirement for an executable?

```java
job.withRequirements("os", "linux").
    "browser" Edge / Chrome / FF
```

Congratulations! With a simple code reuse and few more lines of code you've managed to create a test matrix for 12 different configurations.

**Conclusion**

With Configuration as Code, written in a high-level language, you can create reusable components, create patterns of plans and use parameterisation. Thanks to this you can manage hundreds of complex plans, different requirements, repositories, variables and more with just a few lines of code.
Part 3 - Checkout repositories and build artifacts

Reference

All information that users don't require immediately when performing their tasks should be stored here e.g. glossary of new terms (HLL, LLL, Blueprints), Java Docs etc.

- Create a Bamboo Specs project using Maven Archetype
- Configuring repositories
- Configuring build triggers
- Configuring stages, jobs and tasks
- Configuring artefacts
- Configuring requirements and variables
- <plus miscellaneous>
- Best practices

Configuring artefacts

An artefact definition has name and usually a folder containing files (relative to workspace directory) and a file pattern constituting an artefact.

```java
new Artifact("Artifact Name")
    .withLocation("target/reports")
    .withCopyPattern("**/*.xml")
```

An object identifier

An object identifier is a unique key defining the object in Bamboo, by setting this value you can ensure that the entity will be updated and not created as new one (e.g. after renaming an artefact).

```java
new Artifact("Artifact Name")
    .withOid("unique-identifier")
```

Sharing an artefact

You can share an artefact among other plans. Set the shared property to true and optionally define jobs subscribing to this artefact.

```java
new Artifact("Artifact Name")
    .withLocation("target/reports")
    .shared(true)
```

1. The Artifact list only shows artefacts from jobs in previous stages that have been marked as shared. This is described in Configuring a job's build artefacts.
2. The artefact from the most recent successful build will be used. If there are no successful builds from the artifact-producing plan or
the artifacts have expired, the artifact-consuming job will fail.

Using a shared artefact in another job of the same plane

You can share artefacts between jobs in different stages using artefact dependencies. For example, you may want to run acceptance tests on a build, sharing the same WAR from one job to another without rebuilding it each time. Each time the artefact is shared with a subsequent job, it is copied to the job’s agent.

In the job which shall consume the artefact type:

```java
new Artifact("Artifact Name")
    .withSubscriptions(
        new ArtifactSubscription()
            .withSubscribingJob(new BambooKey("PROJECT-PLAN-JOB1"))
            .withDestination("destination")
    );
```

1. You can refer only to artefacts from jobs in previous stages that have been marked as shared.
2. Destination directory is relative to the build directory. Do not use the absolute path to refer to the destination directory.

Using a shared artefact in another plan

TODO this task is not available yet

You have to use the Artifact Downloader Task for this purpose.

Source Plan The build plan that is the source of the artifact you need to download

Add another artifact to add another artifact to the download list.

```java
new TopLevelPlan(project, planName, planKey)
    .withStages(new Stage("Stage 1")
        .withJobs(new Job("Job1", "JOB1")
            .withTasks(
                new ArtifactDownloaderTask()
            )
        )
    )
);```

Configuring build triggers

Configuring build triggers v6.0

Polling the repository for changes

Poll periodically

You can poll source code repository every N minutes / hours / days etc for new commits. In case a new commit is found, a build will execute.

```java
new TopLevelPlan(project, planName, planKey)
    .withTriggers(
        new RepositoryPollingTrigger()
            .pollEvery(10, TimeUnit.MINUTES)
    );
```

Poll daily, weekly or monthly
You can define a time schedule when to poll the repository. You can poll daily, on specific days of a week or on specific days of a month:

```java
new TopLevelPlan(project, planName, planKey)
    .withTriggers(
        new RepositoryPollingTrigger()
            .pollOnceDaily(LocalTime.of(12, 59))
            // or .pollWeekly(LocalTime.of(12, 59),
            DayOfWeek.SATURDAY, DayOfWeek.SUNDAY)
            // or .pollMonthly(LocalTime.of(12, 59), 28)
    );
```

Poll with cron expression

You can also use a cron expression (see Constructing a cron expression in Bamboo):

```java
new TopLevelPlan(project, planName, planKey)
    .withTriggers(
        new RepositoryPollingTrigger()
            .pollWithCronExpression("0 0/30 9-19 ? * MON-FRI")
    );
```

Repository triggers a build on commit

In order to avoid necessary polling of repositories, you can configure that a repository will notify Bamboo about new commits.

See the Repository triggers the build when changes are committed how to set up the trigger on the repository side.

On the Bamboo side, define the following in your plan:

```java
new TopLevelPlan(project, planName, planKey)
    .withRepositories(
        new GitRepository()
            .withUrl("url")
            .withName("git-repo")
    )
    .withTriggers(
        new RemoteTrigger()
            .withTriggeringRepositories(new VcsRepositoryIdentifier("git-repo"))
            // optionally
            .withTriggerIPAddresses("12.34.56.78")
    );
```

Notes:

- the repositories listed in RemoteTrigger().withTriggeringRepositories() must be also declared in TopLevelPlan().withRepositories()
- use the withTriggerIPAddresses() if you want Bamboo to trigger on post-commit messages from other than the primary IP address for the repository
  - if you use a Mercurial or Git repository then you must type the IP address of your repository host
  - if you use Bitbucket Cloud:
    - for Bitbucket Cloud the current outbound IP addresses can be found at Access Bitbucket Cloud from Behind a Firewall
    - if you’re using the Bitbucket CloudBamboo post-push hook, ensure that the user you are using to authenticate triggering the build has the "build" permission on the plan you are attempting to trigger
- see also Triggering a Bamboo build from Bitbucket Cloud using Webhooks

Cron-based scheduling
In case of the cron-based scheduling, the build will always run at specified time, no matter whether content of repositories has changed or not.

**Schedule with time interval**

You can schedule a build to run every N minutes / hours / days.

```java
new TopLevelPlan(project, planName, planKey)
  .withTriggers(
    new ScheduledTrigger()
      .scheduleEvery(4, TimeUnit.HOURS)
  );
```

**Schedule with daily, weekly or monthly plan**

The schedule can be daily (specific time each day), weekly (days per week), monthly (days per month).

```java
new TopLevelPlan(project, planName, planKey)
  .withTriggers(new ScheduledTrigger()
      .scheduleOnceDaily(LocalTime.of(12, 59))
      // or .scheduleWeekly(LocalTime.of(12, 59),
      DayOfWeek.SATURDAY, DayOfWeek.SUNDAY)
      // or .scheduleMonthly(LocalTime.of(12, 59), 28)
  );
```

**Schedule with cron expression**

```java
new TopLevelPlan(project, planName, planKey)
  .withTriggers(
    new ScheduledTrigger()
      .withCronExpression("0 0/30 9-19 ? * MON-FRI")
  );
```

**Conditional build triggers**

You can choose to run builds of the plan only if other specified plans are currently passing. Those plans must build successfully before this plan will be built. Enable the trigger and tell which plans shall be checked as follows:

**Running a build when another plan has successfully completed**

You may want to trigger a plan build when another plan's build has successfully completed. This ensures that changes to any job's source code associated with one plan does not break the build of another dependent plan (known in this context as a 'child' plan).

Dependencies -> Child plans.

See also Dependency blocking strategies.
```java
new TopLevelPlan(project, planName, planKey)
  .withDependencies(new Dependencies()
    .withDependenciesConfiguration(new DependenciesConfiguration()
      .withEnabledForBranches(false)
      .withBlockingStrategy(
        DependenciesConfigurationProperties.DependencyBlockingStrategy
          .blockIfParentInProgress
      )
      .withRequireAllStagesPassing(true)
    )
  );
```

**Multiple triggers**

You can use many triggers for a single plan. In such case a build will run for a plan whenever condition of any trigger is satisfied.

**No triggers**

You can of course configure your plan to have no triggers at all. In such case the plan have to be executed manually. This is useful when human decision is required, for instance publishing a new product release.

**Configuring plan branches and merge strategies**

. Configuring plan branches and merge strategies v6.0

**Branch detection**

You can configure a plan to detect branches to run builds for them.

Create plans for branches matching given pattern

```java
new TopLevelPlan(project, planName, planKey)
  .withBranchMonitoring(
    new BranchMonitoring()
      .withPlanBranchCreation(
        new PlanBranchCreation()
          .withCreationEnabled(true)
        )
      .withMatchingPattern("^JIRA-[0-9]+.*")
    );
```

**Predefined list of branches**

In Bamboo UI it is possible to manually create plan branches. At the moment this feature is not available in the code. As a workaround, you can create separate plans for each branch.
for (String branch : Arrays.asList("master", "release_1_0", "integration")) {
    new TopLevelPlan(project, planName, planKey)
        .withRepositories(
            new GitRepository()
                .withName("repository-name")
                .withBranch(branch));
}

**Gatekeeper**

Automatic merge

**Branch cleanup**

Time period

What to cleanup

Enable/disable

```java
new TopLevelPlan(project, planName, planKey)
    .withBranchMonitoring(new BranchMonitoring()
        .withInactiveBranchCleanup(new BranchCleanup()
            .withPeriodInDays(30)
            .withCleanupEnabled(true)));
```

**Configuring repositories**

**Repositories**

**Git**

Any Git repository

With SSH authentication *(recommended)*:
new TopLevelPlan(project, planName, planKey)
  .withRepositories(
    new GitRepository(true)
      .withName("repository-name")
      .withAuthentication(
        new GitRepository.SshPrivateKeyAuthentication(sshPrivateKey)
          .withPassphrase(passphrase)));

With user/password authentication:

new TopLevelPlan(project, planName, planKey)
  .withRepositories(
    new GitRepository(true)
      .withName("repository-name")
      .withAuthentication(
        new GitRepository.UserPasswordAuthentication(username)
          .withPassword(password)));

With shared credentials:

new TopLevelPlan(project, planName, planKey)
  .withRepositories(
    new GitRepository(true)
      .withName("repository-name")
      .withAuthentication(
        new SharedCredentialsIdentifier("identifier")))

Bitbucket Cloud

TODO not available in MVP?

Bitbucket Server
```java
new TopLevelPlan(project, planName, planKey)
    .withRepositories(
        new BitbucketServerRepository(true)
            .withName("my-bitbucket-repository")
            .withServer(new ApplicationLink().withName("bitbucket-server"))
            .withProjectKey("PROJ")
            .withRepositorySlug("repository-slug")
            .withBranch("master")
            .withLfs(true)
            .withChangeDetection(
                new VcsChangeDetection()
                    .withCommitIsolationEnabled(false))
            .withShallowClones(true)
            .withFetchWholeRepository(false)
            .withCommandTimeout(Duration.of(30, MINUTES))
            .withSshPrivateKey(sshPrivateKey)
            .withSshPublicKey(sshPublicKey)
    );
```

Plan-local vs linked repositories

We strongly recommend using linked repositories over local repositories.

Linked repositories are available globally to all plans and jobs configured on the Bamboo server. Doing this can save you from having to reconfigure the source repositories in multiple places if these ever change - any changes to a linked repository are applied to every plan or job that uses that repository.

See Linking to source code repositories how to set up linked repositories.

Once the linked repository is set up you can easily refer to it in your plan configuration:

```java
// TODO will this refer to a linked repository? or create one?
.withRepositories(
    new GitRepository(true)
        .withName("repository-name")
)
```

You can also easily create new linked repository.
